RURAL LIFE

Described and Illustrated,

IN THE MANAGEMENT OF

HORSES, DOGS, CATTLE, SHEEP, PIGS, POULTRY, etc., etc.:

Their Treatment in Health and Disease;

WITH AUTHENTIC INFORMATION ON ALL THAT RELATES TO

MODERN FARMING, GARDENING, SHOOTING, ANGLING, etc., etc.

BY JOHN SHERER, F.R.G.S.

AND A

COMPLETE SYSTEM OF MODERN VETERINARY PRACTICE.

ILLUSTRATED.

THE LONDON PRINTING AND PUBLISHING COMPANY, LIMITED,
LONDON AND NEW YORK.
Preface.

Deferring to the opinion that the end of all writing ought to be instruction, the following pages have been produced with this end constantly in view: but as instruction may belong to the past, without, as well as within, the limits of existence allotted to man, the object in Rural Life has been to approximate as nearly as possible to the present, in order that, while we are in the land of the living, we may be participators in the enjoyment of the knowledge which, not only in Rural Life, but in every other condition, is daily developing itself around us. Thus, then, this Work has been produced in accordance with the approved principles of the most experienced, intelligent, scientific, and practical men of the present day, engaged in the pursuits of which its pages are the record; and the information it contains is brought down to the time of its publication.

Another end which has been kept in view in the production of Rural Life, is simplicity and clearness in the arrangement. This, it is believed, has been obtained, not only by laying the Work out in divisions, as a horticulturist does his ground, but in subdividing these into chapters, and these, again, into paragraphs, with, in many instances, separate or independent "headings." This, it is thought, has greatly tended to simplify its arrangement; to lighten any heaviness which might otherwise have appeared in some of its pages; to facilitate the desire of reference; and, altogether, to render Rural Life less wearisome in the perusal. As all pleasure consists in variety, the subjects have been disposed in such a manner as, it is hoped, will secure the reader, whilst seeking for information, from being baffled by confusion, or disgusted with dulness.

The veterinary portions may, by some, be considered of the first, and by others of the last, importance. But however this may be, they have been
carefully compiled, and not a single recipe given, except upon the authority of well-established practice. In treating such a subject as Farriery, a due degree of delicacy has been observed in the phraseology, but never to the sacrifice of perspicuity. He who would prevent, alleviate, or cure the maladies of brutes, must, in addressing those who may be ignorant of the scientific technicalities of language, be permitted some latitude of expression, in order that what he desires to be done, may be sufficiently understood by those on whom the duty of carrying out his recommendations is to devolve. To the other divisions of Rural Life equal attention has been given; the principal object having been to reproduce, in as clear a form as possible, the most recent information on the various subjects of which it treats.

The Engravings are by several of the highest animal artists of whose names this country can boast; and they have, as may readily be conceived, been produced at great expense. But that which is scarce and good must always command a price proportionate to its value. The original drawings from which the Engravings have been made, being of a class in which excellence is rarely attained, they have been procured with a view to enhance the interest and value of Rural Life; and it is hoped, that the laudableness and realisation of the desire, will secure the accomplishment of the end.

J. S.

London.
GENERAL INTRODUCTION.

Among the ancients, the literature of Agriculture occupied a far higher place than that to which it has attained in modern times; although, within these twenty years, Great Britain has made immense advances in the practical manipulations of the science. Mago, the Carthaginian, who is supposed to have flourished in the time of Darius, and to have been the founder of the great Punic family, from which Hannibal sprung, is declared to have been the father of agricultural literature. After him come Hesiod, Theophrastus, Xenophon, Cato, Varro, Virgil, Columella, Pliny, and Palladius—all of whom say something, more or less, of Agriculture. Among the writers on this science, if there were no great kings, there were certainly great generals. Columella tells us, that Mago, the Carthaginian, and Hamilcar, did not consider it beneath their dignity, when not engaged in the operations of war, to contribute, towards the general stock of human knowledge, treatises on farming. The books which Mago wrote on the subject amounted to twenty-eight, which were so highly esteemed, that, on the final destruction of Carthage, when the whole of her literature was handed over by the Romans to their African allies, these were specially excepted, carried to Rome, and ordered, by the senate, to be translated at the expense of the public. Such an honour proves the estimation in which his books were held; whilst it shows how deeply interested the Romans were in the subject of Agriculture. On neither Greek nor Carthaginian Agriculture, however, have we the means of gathering very much information. In reference to Greece, we know that Attica was arid, and Laconia full of swamps; that Megara was deformed with rocks; and that Corinth depended on foreign importations for her food-supply. But this is not telling us much; although she could not have been destitute of an agricultural literature, since Pliny laments the loss, in his day, of forty treatises upon the subject. The incidental notices of Herodotus and Thucydides do not yield us much information; and although we have the work of Theophrastus come down to us, it is not very satisfactory as a book on husbandry. The Economics of Xenophon are said to have been composed on a farm, which he had bought and occupied near Smyrna, and which is frequently appended to the Memorabilia. Farming, gardening, household management, and instructions relative to the government of wives, form the staple of its pages; and it contains the passage in which Cyrus the younger presents himself to Lysander in the character of "The Persian Farmer."

Passing from Greece to Rome, Cato the censor is the first distinguished personage that rises before us as an agricultural writer. He inherited from his father a Sabine farm, which he cultivated himself, but rather parsimoniously than otherwise. He was by no means an advocate for "high farming;" but preferred limiting his outlay to making active efforts at improvement. He died 150 years before the birth of Christ; and left room for Varro, one of Pompey's generals and admirals, to take his place in the list of writers on rural affairs. His work, entitled De Re Rustica, has descended
to us, and proves him to have been a practical farmer; although he chiefly relies upon the maxims of Mago, and some Greek writers, for the mode he pursued in cultivating the soil. He lived nearly throughout the century which immediately preceded the Christian era; and was, for some time, librarian both to Julius and Augustus Caesar. Virgil comes next; for Cicero can hardly be included in the list. The Georgics are poems of great originality, embracing much smoothness of versification, and elegance of diction, with precise, ample, and sound directions for the husbandman. To him succeeds Columella, who was a native of Spain, and apparently born about the time of the Christian era. His work has come down to us almost entire, and is divided into twelve books. Two of these are on farming and farming premises; but also contain some directions on the selection and management of agricultural slaves: three on the vine, olive, and orchard fruits; two on farming and domestic animals, from which he excludes the sporting-d g; one on poultry; and one on bees. In the ninth book he breaks into verse on the subject of gardening; and in three more books treats of the bailiff, his wife, wine, vinegar, jam-pots, and the kitchen garden. Pliny comes next. He died in A.D. 79, and was succeeded by Palladius, who wrote fourteen books of a farmer's calendar, and a poem on the art of grafting. He was a landed proprietor in Sardinia, and also near Naples. As an agricultural writer he is not very highly spoken of; although, in the middle ages, his work was held in considerable estimation.

The names we have thus given of the ancient writers on rural affairs, are spread over a period of eight centuries; and yet, throughout that long lapse of time, we look in vain for any sign of the science of Agriculture being considered a progressive art. There is not the smallest evidence of improvement. With the single exception of lucerne, there is no new object of culture introduced; and the system which the father unvaryingly pursued, seems to have been equally unvaryingly followed by the son. What were its characteristics is determined in a very few words—system, accuracy, carefulness, and a sharp eye against waste. The whole of the maxims of Cato have a tendency to the repression of outlay; and the consequence was, that the productive powers of their lands decreased, as the soil became exhausted from the frequency of the crops. What is called high farming—by which is meant a large expenditure, with a view to increase produce—was out of the question; and instead of looking forward with a view to the means of success, the Roman farmer seems rather to have possessed the faculty of looking backward, in order to preserve himself stationary in his position. This, of course, was fatal to advancement; and hence the dreary waste of his years, as well as of his lands, in the agricultural course he pursued. Under the division on farming, in the following pages, this subject is noticed in greater detail.

Of the system of farriery, as practised among the ancients, we possess very little knowledge. We have, occasionally, a slight notice from Columella, who treats at length on the general management of cattle; and in Renatus, who flourished a couple of centuries later, the subject of animal diseases is more elaborately handled. He urges the necessity of a high cultivation of the veterinary art, not only as being a source of pecuniary gain, but as being the means of enlarging our sympathies with the sufferings of the lower animals. With the exception of the necessarily crude and imperfect performances of these two writers on this subject, no ancient treatise, bearing directly on the diseases to which animals are subject, and composed by a professional man, has descended to us. There are no evidences whatever, in the writers just named, that they were acquainted with the sciences of anatomy and physiology—a circumstance
somewhat singular, as, both in Egypt and in Greece, considerable progress had been made in human and comparative anatomy. Among the ancients, Celsus is the only physician of celebrity who is said to have written on veterinary medicine; whilst Xenophon is the most ancient Greek writer who has specially written upon the horse. His performance, however, is confined to the training of the animal for war and the chase: it is supposed, however, that the ancients had a knowledge of the disease which is called the "glanders," and was known under the denomination of the "moist malady."

Whatever merit may be assigned to ancient writers on veterinary art, arises from the dietetic rules, and the works of domestic management they have bequeathed to us. In other respects they were but in their novitiates. They were powerful in the art of purging; but what they have left us on the symptoms of disease, has not tended to advance our knowledge; although it is an evidence that they were not inattentive observers, however far they failed in the application of the proper remedies. In bleeding they were as great as in purging; but whatever were their drawbacks, they were much superior, not only in learning and eloquence, but even in professional ability, to the vast majority of their pupils of the fifteenth, sixteenth, and seventeenth centuries. At these periods, the mental gloom, which had so long darkened the European continent, began to be dispelled, when, with the general dawn, the works of the ancient veterinary writers became objects of search and desire; and, as fast as they were found, they were translated into the Italian and the French languages. The art became a study. Ruini and others described, anatomically, the body of the horse; schools began to be established for professional instruction: and, notwithstanding the immense advantages which have arisen from the general diffusion of knowledge, the labours of these first teachers, after the revival of learning, must still be acknowledged with respect and gratitude. The medicinal part of veterinarianism was more generally cultivated, and, at least in some instances, under accredited medical professors. Every branch of the equine economy—whether as regards the harness or the trappings, equitation, the military ménage, or the riding of the horse; the methodical treatment of the foot, accompanied with the invention of various forms of iron shoes, as well as their scientific adaptation to the foot—were eagerly pursued, and mostly with success. In the shoeing department, one Cesar Fiaschi greatly distinguished himself; and either invented or recommended the welted shoe as a substitute for calkins and forknails, which were then in use. He is also said to have invented the lunette, a sort of short shoe in the shape of a half-moon, which, since his time, has met with favour from some of the faculty.

The new art having rapidly diffused itself over a large portion of the European continent, soon reached England, where the cure of diseased or injured animals had, from time immemorial, been given over to the tender mercies of leeches and farriers, whose ignorance generally was only rivalled by their inhumanity. In proof of this, an expression of Markham, a writer on the subject, is confirmative. "Other torments there are," says he, after expatiating upon his cures by the use of fire and the knife. It is probable that the future scintillations of knowledge, first received in this country, occurred in the days of the Tudors; as we learn from Blundeville, who wrote in the reign of Elizabeth, that French and German farriers were not only employed by the queen, but, in general, by the English nobility and gentry. Yet the progress of our practitioners was slow—possibly arising from the greater amount of countenance being given to the foreigners; but from the period of which we now speak, to that of the earlier
part of the eighteenth century, veterinarianism in England, like the lengthening chain of Goldsmith, only dragged its slow length along. No medical name of the smallest scientific pretensions appears on the veterinary list throughout that long, dreary interval in the medical, surgical, or anatomical branches of the art. To be sure, there is a person of the name of Snape, who crops up, and who was the farrier of Charles II. The family of this man, it appears from his book, had, for upwards of 200 years, served the crown in the capacity which, it is to be hoped, he himself worthily filled, as he seems to have been tolerably informed. His anatomical system, arrangements, and nomenclature, were a copy of the Italian school; but he was a dissector himself, and described from his own observations. Besides Snape, there are the names of Stephens, Martin, Clifford, and Morgan, all of whom are early writers on the veterinary art; but they are of no merit. Neither is the work of Mascal, the farrier of James I. This book is ludicrous in the extreme; and it may be taken as a significant sign of the ignorance of the age when he wrote in reference to farriery, that his book passed through numerous editions, notwithstanding that there were other national and even learned treatises on the same subject. It is difficult to account for this: but he was the king's farrier; and as there is something in position and a name even in these enlightened days, it is probable that there was a similar something in those of the Scotch Solomon who sat upon the English throne. To the above list may be added the names of De Gray and Gervase Markham, who continued to publish till after the Restoration. Markham's works have been said to comprise "every absurd, barbarous, and abominable juggling trick," as well as every useful invention which had, up to his time, issued from the brains of either ancients or moderns. Whatever may be the defects and deformities of the works of Markham, however, they had a rapid and widely-extended sale. They enjoyed a high reputation down to the days of Gibson; and even long afterwards were held in esteem among the country leeches and farriers. Fame of this sort is indicative of some merit. Mankind in general are slow to give praise where it is not justly due; and that which was conferred on the works of Markham, seems to have endured longer than that which was extended to preceding writers on the same subject. It is allowed that his work contains the amallest details of the practice of farriery as then in vogue, with delineations of the instruments in use, not very differently contrived from those employed in the practice of subsequent professors. As a specimen of the nonsense with which some of the writers on farriery disfigured their works, we may instance an example from Dr. Gray. In a case of furcey, this sage equine Esulapius orders the medicine to be administered to the ears of the horse, and drawn up therein. In a case of lameness, he orders a turf to be cut and secreted; and in proportion as the turf decays and wastes away, so shall the lameness of the animal gradually depart. Could folly go further? Yet men like these were the persons who took upon themselves the cure of the noblest of the lower race of animals, when unfortunately fallen ill or laid up by some injury, which, in all probability, nature herself would have cured, but for the officious assistance of these sagacious practitioners. In the reign of Elizabeth, a person of the name of Blundeville wrote a fashionable treatise on the "Horse," based on the practice of the continent; and, in the following reign, Baret produced his Hipponomie, or the Vineyard of Horsemanship. In this work is discussed the relative branches, including the principles and practice of racing, and of that system of equitation peculiar to England. This is followed by a huge folio by the Duke of Newcastle, who enters into details upon the regular management of the horse,
according to the method of the continental schools. Yet whatever light had, as yet, been thrown upon the subject of veterinary art, down to the reign of George I, the medical care and treatment of horses, and other domestic animals, was confined entirely to the leeches, farriers, and cow doctors of the period. Such was the deplorable condition of this art down to the early part of the eighteenth century, when it attracted the attention of William Gibson, who had acted as an army surgeon in the wars of Queen Anne; and who, to a sound judgment, seems to have added the essentiality of practical knowledge. He was the first professional man who, in this country, made the attempt to improve the veterinary art; and, like all men of sense and observation, seems to have commenced in the right way. Reasoning analogically, he gave those, or similar, medicines which acted favourably on the human system, to such animals as were affected with the same or a similar class of diseases. His work on farriery forms an era in the annals of veterinary literature; and the fundamental parts of his system became the basis of a very superior practice. A second edition of his work appeared about the middle of the eighteenth century, when it was followed by another excellent work on the same subject, by Dr. Bracken, a physician of Lancaster. After him came Bartlet, a surgeon in Bow Street, Covent Garden, who was rather a compiler than an originator of the art. He, however, was the first to introduce the impracticable system of short-shoeing, which had, at that time, been practised in France by La Fosse, a farrier of considerable experience, and a great practical veterinary anatomist. As Bartlet had no pretensions to the art of horse-shoeing, he adopted the rules of La Fosse; and these, fanciful as they seem to have been, operated beneficially on the practice of England, as it then existed. The subject, however, was not suffered to rest here. A Mr. William Osmer, a surgeon and a sportsman, took it up, and published an excellent treatise on horse-shoeing, reducing the speculative rules of La Fosse to the standard of his own, and that of English experience generally. His book proved of great usefulness; and being written in a plain and popular style, found its way into the hands of great numbers of the shoeing-smiths throughout the country. Those who had horses, and valued them, were now alive to the importance of the subject of horse-shoeing. The Earl of Pembroke wrote a treatise on it, and Berenger published a respectable work on the grand ménage. Clarke, then king’s farrier for Scotland, issued a couple of superior treatises on shoeing, and on the prevention of diseases in horses; and the eighteenth century may be said to have become prolific in veterinary publications and practice. France took the lead in the movement; but a zeal for the improvement of this branch of science also pervaded Germany, and other continental states. Colleges were founded and established in various countries, in which the science has since continued to be regularly taught. A catalogue of the various continental writers on black cattle and sheep, was made and published in the Giornal di Letterati, of Italy. Since that time, the writers on veterinary science on the continent have greatly increased, although comparatively few of them have found their way into this island through the medium of our language.

We have now arrived at 1792, when the Veterinary College, St. Pancras, London, was established for the treatment of the maladies of all domestic animals. At first, however, the institution did not flourish; but it gradually gained ground; and now, a much more widely-extended view of the benefits to be derived from its instructive modes of practice to all kinds of domestic animals, is receiving a more favourable recognition. A large number of valuable veterinary publications have issued from the press since the commencement of the present century; and these are still increasing.
GENERAL INTRODUCTION.

The structure of the horse, the diseases to which he is subject, and the injuries to which he is continually exposed, have been investigated with the greatest success, not only in Great Britain, but in other countries. Associations have been formed, and colleges founded, for the advancement of veterinary science; and eminent practical professors are engaged in the dissemination of its principles; so that it has now taken a very elevated position. Its practice is no longer left in the hands of the uneducated and unskilful: the horse, the dog, and the beasts of the farm generally, are no longer subjected to the tortures of callous-hearted and presumptuous ignorance, but are placed under the care of gentlemen who have gained the general respect of the community, and the confidence of those with whom they come in immediate contact, and whose experience, intelligence, and humanity entitle them to the onerous position their profession calls upon them to fill.

As it is hardly possible to over-estimate the value of the Dog to mankind, a comprehensive, yet sufficiently full description of all the species of that animal, will be found in the division assigned to their treatment. In the most primitive ages, the dog was the follower and the friend of man; and so much has his wonderful sagacity, united to his physical qualities, excited the admiration of some nations, that they have even bowed the knee, and worshipped him. In the first books of the Scriptures he is frequently mentioned, but not as an animal which had taken its place among the wild beasts. He is spoken of as one which had become domesticated, and had already identified himself with the social attributes and idiosyncrasies of the lords of the creation. From the remotest times he was held in especial veneration by the Egyptians; was actually worshipped at Hermopolis the Great; and, shortly afterwards, in all the towns and cities of Egypt. Juvenal tells us, "that whole cities worship the dog (Anubis); no one Diana"—a lamentation in which, no doubt, numbers of his mythological countrymen would join. Subsequently, Cynopolis, the "city of the dog," was built in honour of that animal, and splendid festivals instituted in his honour. In the Greek mythology he plays a no less prominent part, and guards the gates of Hades in the form of Cerberus, with three heads, as being indicative of the extreme watchfulness of his character. The Persian fire-worshippers, like the Egyptians, paid him divine honours, and elected his shape to symbolise the Good Principle, which enabled them to baffle the powers of evil, when assailed by them. By the modern Parsees he is still held in high veneration. Leaving the East, and crossing the Atlantic for the West, we find it stated by De la Vega that the Peruvians formerly worshipped the dog; but it somewhat detracts from any spiritual character with which they may have thought him invested, when we are told that they fed upon his flesh at their festivals.

If these facts exhibit the profound superstition of the different nations of whom they are recorded, they also go far in proving the possession of qualities which, in this animal, entitles it to universal esteem. But it need not be a subject of wonder why the dog has always held such a high and honourable place in the affections of mankind, as it is his nature to participate in the general enjoyments, sports, pastimes, and even duties and cares of those with whom his lot is cast. Those who have given the slightest study to his habits, must have observed how soon he moulds his disposition to that of his master, or that of the family with whom he is taken into membership. If he should chance to be the property of a poacher or a ruffian, his character usually degenerates, as his nature invariably assimilates itself to that of his possessor. Like his master, he becomes a sort of lawless animal, surly, gross, and rude, and ready for any sort of rough
GENERAL INTRODUCTION.

and terrible work that may fall in his way; but if he belong to a family in which order, regularity, gentleness, and good moral dispositions prevail, he is seldom other than an animal of great kindness and sociability. He becomes so tractable and docile that he really sometimes seems to know the character of the conversation which is being carried on; and by the silent attention with which he lies and listens, with open eyes, to conversation, one would almost believe that he understood the whole meaning of what was being said. We have had dogs by the score; and the last one we had possessed the peculiarity of frequently sitting before us, and, when we were reading, scanning our countenance for a quarter of an hour at a time, with a curiosity and an interest which no disciple of Lavater ever surpassed. He sometimes literally gazed us out of countenance, and must have profited wonderfully by his study, as he was a rare physiognomist; which, however, we think all sagacious dogs, more or less, are. The docility and intelligence of the dog, however, are in no situation witnessed to such a remarkable extent as when he has been thoroughly broken-in for the purposes of the sportsman in the field. Here he may be said to be, not only the companion, but the leader or director of his master; in every sense of the word, a real *pointer*, that, by his action and motions, indicates not only the direction, but *points* to the very spot where the game shall be found. The possession of the qualities requisite for a service of this kind naturally brings him into intimate relationship with our rural sports, more particularly those in which the gun takes a prominent part. This being the case, he has been, when opportunity occurred, introduced in the following pages, in the division assigned to *SHOOTING*; where, also, is introduced a condensed account of such birds and beasts as come under the denomination of *game*, which, in this country, confers upon them the privilege of legislative protection. In this division, a brief history of the gun is also given, down to such weapons as were exhibited in the International Exhibition of 1862; and, in order to complete this portion of the work, a description of the needle-gun—which may yet become a sporting instrument—so fatal to the Austrians in the late war, has also been given.

“He to whom an abode in the city lies close at heart, has no need of a country estate,” is one of the maxims of Mago; but he may, for all that, take a lively interest in witnessing, in the field, the massive development of our bovine breeds. Accordingly a large division has been, in the following work, devoted to the description of such of our breeds of black cattle as have been brought to the highest state of perfection. The ancient Carthaginian just quoted made the form of the ox a study, and wrote upon the best means of preserving it in health. “Upon the health of black cattle,” says Varro, “I have borrowed a good deal from the books of Mago, which I make my herdsmen carefully read.” We like this. All agriculturists should follow the plan of Varro, and make their herdsmen peruse the best works on the management of cattle, sheep, and such animals as form the stock of a farm, and come more directly under their care and management. It may interest our readers to peruse the directions of Mago for buying oxen for the plough. The translation is from a minutely critical article in the *Quarterly Review*. “The young oxen which we buy should be square in their form; large limbed; with strong, lofty, and dark-coloured horns; broad and curly fronts; rough cars; black eyes and lips; prominent and expanded nostrils; long and brawny neck; ample dewlaps, pendant nearly to the knees; a wide chest, and large shoulders; roomy-bellied, with well-boned ribs; broad on the loin, with a straight, level, or even slightly depressed back; round buttocks; straight and firm legs, by no means weak in
the knees; large hoofs; very long and bushy tails; the body covered with thick short
hair, of a red or tawny colour; and they should be very soft handlers." Oxen answering
to this description would meet with favour even at the present day. As the subject of
cattle, however, has been fully treated in the following pages, we will dismiss it here
with the remark, that the live-stock of Great Britain are distinguished by the early
period at which they become ready for the butcher; the enormous amount of food they
yield in return for the provender they consume; and the great proportion of meat, of
the finest quality, to be obtained from them.

With the general development and improvement of everything belonging to
agricultural science, the sheep has come in for a large share of attention; accordingly, it
is amply treated of in the division assigned to it. The various breeds are detailed; and
the manner in which Mr. Bakewell, of Dishley, proceeded to found his celebrated
Leicesters, has been, singularly enough, chosen by Archbishop Whately to illustrate a
position in his treatise on Logic. To the scholastic mind, sheep and logic, brought
into association by a reasoning archbishop, may sound somewhat strange; nevertheless,
one portion of Bakewell's mode of proceeding is so clearly set forth by the archbishop,
that we will make no apology for placing it before the reader. "He (Bakewell) observed,
in a great number of individual beasts, a tendency to fatten readily; and in a great
number of others, the absence of this constitution. In every individual of the former he
observed a certain peculiar make, though they differed widely in size, colour, &c. Those
of the latter description differed no less in various points, but agreed in being of a different
make from the others. These facts were his data. * * * * His principal merit
consisted in making the observations, and in so combining them as to abstract from each
of a multitude of cases differing widely in many respects, the circumstancese in which
they all agreed." This, as the archbishop has stated it, was the secret of Bakewell's
success. He chose the animals of the form and temperament which indicated the surest
signs of producing fat and muscle; at the same time declaring, that all that was not
beef in an ox was useless. Thus there was nothing like beef and mutton in the eyes of
Robert Bakewell; and he himself seems to have been a pretty fair specimen of his own
rearing, for he was tall, stout, broad-shouldered, and of a brown complexion; clothed in
a brown loose coat, and scarlet waistcoat, leather breeches, and top-boots. In sheep,
however, he regarded size as a vulgar test of merit; endeavouring to secure a circular
body, with as short legs as possible; a small head; small neck and bones. It is well
known that fat people are not generally large in bone. John Hunter, the great physiolo-
gist, confirmed, at least in one essential particular, the observations of Bakewell; for he
affirmed that, in the human subjects he had examined, he found that small bones were
the usual concomitant of corpulence.

The hog has also received its full share of attention. Both the habits and
appearance of this animal are calculated to excite, in a remarkable degree, feelings of
disgust; yet it is an animal of immense value to mankind. It has emphatically been
designated the poor man's friend; and there is no other which comes within the
boundaries of the farm-yard more deserving of the distinction. Its flesh is, by tens of
thousands, highly relished, in all the forms in which it can be put upon the table; and
however unintelligent, stupid, stubborn, contrary, or perverse it may seem in its
disposition, its docility has been frequently proved to be such as to excite general
wonder. To its management in health, and its treatment in disease; to the various
breeds which have extended its reputation; and to the care which is necessary to bring
it to the high state of perfection to which it is capable of attaining, a considerable portion of the following pages has been devoted.

Taking a comprehensive view of the subject of Poultry, it will be found that, in an extensive collection, the geographical history and commercial progress of the civilised globe might, with no inconsiderable degree of certainty, be indicated. “Thus,” says Mr. Richardson, “the peacock* represents India; the golden pheasant, and a tribe of lucks, China; the turkey (pride of our yard and table) is one of our many debts due to America; the black swan (rival of the snowy monarch of our lakes) reminds us of our Australian discoveries; while Canada and Egypt have each their goose. The large, fat, white ducks—models of what a duck should be—are triumphs of British breeding, and afford a specimen of one of the best productions of Buckinghamshire, since John Hampden. When, however, we turn to the fowl varieties, we find that Spain and Hamburg, Poland and Cochin China, Friesland and Bantam, Java and Negroland (besides our native Surrey, Sussex, Kent, Suffolk, and Lancashire), have each a cock to crow for them in our poultry-yards.” It is further to be observed, that the same close attention to the proper kinds of food, warmth, and symmetry of form, which have built up to their present perfection our short-horned cattle, Leicester sheep, and thoroughbred horses, have similarly brought out the improving qualities of the fowl. It is thus that the elegant, though diminutive and spirited, Bantam has been produced; as well as the beautiful Spanish and Poland fowls. In 1826, when poultry shows were first established, with a view to draw a wider range of public attention to this branch of rural life, they extended into many parts of the kingdom; and, gradually increasing, they were, by 1860, so numerous, that there was hardly a district in England, of any consideration, but could boast of its society for the improvement of poultry. Even the Crystal Palace, at Sydenham, has had its shows of poultry, pigeons, and rabbits. This has not been without its advantages, as it has enabled agricultural visitors to London to compare what has been doing in the way of improving the lesser denizens of the farm-yard; whilst at the annual Smithfield cattle show they are enabled to note the development of meat and fat, and the diminution of offal and bone, in the more stately occupants of the stall and the meadow. What the last half century has done for cattle, sheep, and swine, a comparatively limited period has sufficed to effect for the several varieties of domestic poultry. The increase of size and weight of all classes of improved fowls, is now so much a matter of course, that, to secure prizes, they must combine with those essential requisites, high condition, quality, beauty of plumage, purity of race, and even uniformity in the markings, as well as in the size and form of the comb and wattles. To all these particulars due attention has been given in the division in which the treatment of poultry will be found.

A few years since, some Englishmen accepted an invitation from the French government, to cross the Channel with their best live-stock and implements, and enter *At the siege of Lucknow, a touching incident occurred in connection with this beautiful bird. When the besieged were broken with sickness, sorrow, and comparative want, one day a bright-winged peacock lighted on one of the buildings of the beleaguered town, and attracted the eyes of many of the brave, though forlorn, inhabitants. How a taste of the fresh food of that bird would have been relished! Several muskets were presented at it; but, with an indescribable sense of humanity, they were lowered again, and the beautiful stranger was suffered to fly away uninjured. Yet, at that instant—

"Man's inhumanity to man"

was making countless thousands mourn.
into competition with the picked agricultural and mechanical skill of continental Europe. Arrived at the appointed spot, and the comparison made, it was found that they were almost immeasurably in advance of their neighbours in the arts and sciences necessary to the product of meat and corn in the most economical manner, although they worked under a climate not remarkable for its congeniality, and on a soil which has, for ages, been denuded of its virgin fertility. This must have been rather surprising, if not disheartening, to continental growers, breeders, and machinists; but the best evidence of the superiority of British live-stock, and agricultural machinery, is not to be proved by the medals awarded in Paris or Vienna, but in the constantly increasing exportation of both to all parts of the world where scientific cultivation has superseded the ruder modes of by-gone times. In regard to improvements, said the Earl of Carlisle, in addressing an agricultural meeting of Yorkshiremen, "I saw, on the plains of Troy, the clod-crusher of Crosskill; the drills, the horse-shoes of Garrett; and the ploughs of Howard and Ransome:" and, on the banks of the Danube, the Scheldt, and the Po; of the Mississippi and the Amazon; on the shores of the Baltic and the Black Sea; in Australia, and in Flanders (the cradle of modern agriculture), to English implements is given the same preference as that which is awarded them on the more classic ground of Troy. In so far as our own island is concerned, it has now, for some years, been proved, that the application of steam machinery to the cultivation of the soil, is, in many ways, preferable to the modes usually followed; and models of engines for the farm, which formerly appeared at our cattle shows, are now replaced by the machines, these represented in working order. This is the case at the Smithfield cattle shows, where the machines of several inventors are exhibited, accompanied with hundreds of testimonials, detailing the practical experience of those who have become purchasers, and who have given them a fair trial upon their own acres. The exhibition of these, united to the very extensive evidence in their favour, whether used on the churlish "clays," or the "lighter" soils, completely establish every essential point in the question of steam-power tillage. The saving of one-third of the farmer's teams, on a large holding, repays, in a few years, the prime cost of a steam plough; while two small farmers can join in the purchase of an apparatus too costly for one. The employment of several hundred machines in breaking up many thousands of acres in a single season, has demonstrated that the work is profitable, in point of economy, over horse labour; more profitable in the points of excellence and efficiency, and still more profitable in the point of augmented produce. From these circumstances, and the importance of the subject, a division has been devoted to the practice of modern Farming and Agricultural Machinery, in order that the gentlemen who keep their own horses, farm their own estate, and grow their own beef and mutton, may have at hand a means of reference, in Rural Life, to suggest such improvements as may arise from the perusal of its pages.

The cultivation of a garden was the only occupation of our first parents in Paradise; and from that hour to this, it has been considered, even by those whose position is such as to have placed one within the reach of their power, to be the purest of human enjoyments. "How did you endure your poverty?" asked Alexander the Great of Abdalonus, a Sidonian prince, who had been reduced from a throne to earn his livelihood by cultivating a garden with his own hands. "May Heaven enable me to bear my prosperity as well! I then had no cares, and my own hand supplied all I required." In this condition he was independent; and independence
and contentment are greatness and happiness united. The practice of horticulture, no doubt, helped to occupy, at least, much of the leisure hours of the patriarchs: Homer's garden of Alcinous enjoyed an eternal summer; and the fruits it produced were the apple, the fig, the pomegranate, the pear, the olive, and the vine, watered by a couple of fountains, and encompassed by a hedge. Judging by the mythology of the Greeks, they must have been great admirers of gardens, as well as lovers of flowers and vegetables, as they sought to identify some of the most essential and beautiful products of the earth with the deities whom they worshipped. Thus, the oak was sacred to Jupiter, the maiden-hair to Pluto, the cypress to Narcissus, and the lily to Juno. Ceres had the poppy, Minerva the olive, and Venus the apple, the myrtle, and the rose. Flowers, in general, were supposed to have sprung from the tears of Aurora; while the trembling of a leaf, or the waving of a few blades of grass, indicated the passing of the breath of Zephyrus. All this is redolent of the fine imagination and delicious sweetness which characterised the taste of the old Greeks. The Romans, too, had their horti, both flower and kitchen; and the Piso, the Fabii, the Cicero, the Lentuli, and other distinguished names, are derived from ancestors celebrated for the successful cultivation of those vegetables to which these names were attached. The Britons, in the time of Strabo, had plots of ground combining the properties of a kitchen garden with those of an orchard; and, after the introduction of Christianity, A.D. 507, gardening was practised as an art congenial to the manners of the Saxons. Under the Danes horticulture continued to advance; and, on the establishment of the Normans in this country, we find various notices, not only of public, but of private gardens being attached to the dwellings of the people. In 1107, Brithnod, Abbot of Ely, flourished, and is spoken of as being an improver in gardening. "He performed a great and useful work," says the historian of his monastery: "being skilful in the art of planting and gardening, he laid out very extensive gardens and orchards, which he filled with a great variety of herbs, shrubs, and fruit trees." Notwithstanding this, however, it is questionable whether there was either taste or design in the disposition of his flowers, vegetables, and fruit trees; although we think it hardly conceivable, that a man could take delight in an occupation without evincing some principles of design in view, that it might give a greater zest to his pleasures. But be this as it may, it would appear that, before the reign of Elizabeth, the art of gardening was nothing more than a piece of mechanical routine. It had, so to speak, neither taken shape nor form; but was pursued as it had always been pursued—namely, without departure from the stereotyped modes of preceding horticulturists. The mighty and majestic lie, however, had a great taste for flowers; and it was in her reign that the first regular establishment for the scientific cultivation of plants took place in England. Her successor was also a great patron of gardening; as was his son, Charles I., in whose reign the first glazed edifices for the preservation of tender plants were erected. All this, however, is described more at length in its proper place; as, also, is the most approved practice of horticulture in fashion at the present time.

In intimate association with fruits and flowers is the bee, an insect which has, perhaps, attracted more attention, and undergone more careful examination, than any other of the insect tribe. To this busy little creature it was deemed necessary to devote a brief division in the following work, that those who are in possession of a garden may gratify the natural desire of giving an occasional minute to watching the activity with which it seeks and dives into those flowers in which it finds the nectar upon which it
subsists, and the honey which it produces. For a very long period, the most diligent observers were totally at a loss to account for some circumstances in its history; therefore published to the world the most conflicting statements. At length, the Genevese naturalist, M. Huber, appeared; and, in a little work, published during the first decade of this century, he cleared away the difficulties. Many of the habits and instincts of the bee, unknown to our grandfathers, appear in the following pages.

Angling is a sport peculiarly congenial to the quiet of Rural Life, and has found suitable treatment in its proper place. The salmon has not been largely dealt with, notwithstanding that those who favour the pastime, consider the capture of this fish by the rod as their noblest prize. When this monarch of the stream is hooked, nothing can be more exciting; and the enthusiast, after an hour of terrible anxiety and skill, who lands him fairly upon the bank, we verily believe would feel less glory in having a Roman triumph voted to him, than in surveying the fair and silver side of his beautiful captive, now stretched at length upon the green grass. For the delights of angling we have stores of literary authorities. From gossiping Isaac Walton, down to John Wilson, the Christopher North of the Noctes Ambrosianae of Blackwood, we have the names of many literary lovers of the sport recorded. Even long before their day, the use of the rod was a delight to some of the lovers of literature. The great Raleigh, when banished from court, took to it as a recreation and a pleasure; and Archbishop Laud, in an epistle to Lord Strafford, in 1638, thus alludes to the salmon, when reposing from the cares of government, at his new residence in the woods of Wicklow:—"I find by your letters you are gone a hunting. I hope you will find time to go a fishing too; for I mean to be a very bold beggar, and desire you to send me some more of the dried fish (I do not know what you call it) which you sent me the last year. It was the best that ever I tasted." To this he adds—"Do not think to stop my mouth with more of your hung beef from Yorkshire, which was as hard as the very horn the old runt wore when she lived." It is supposed that the archbishop here alluded to salmon, preserved after the manner of the Scotch, who call it kippered. Cotton, the poet and voluptuary, occasionally fled from the world of gaiety in which he lived, to enjoy the pleasures of the rod: Davy left his laboratory; and even the ethical Paley quitted his desk and easy-chair, that he might enjoy some quiet hours by the stream, where meditation unites with silence to lead a man to thought and reflection.

Such is a brief résumé of the subjects treated in the following pages; and as information, rather than amusement, is their aim, it is hoped that the labour of producing them has not been spent in vain, but that their end will be accomplished.

JOHN SHERER.

London.
RURAL LIFE
DESCRIBED AND ILLUSTRATED.

DIVISION I.
HORSES.

CHAPTER I.
THE EARLY AND ANCIENT HISTORY OF THE HORSE.

As it is impossible to ascertain, with any certainty, the original country of the Horse, it is, in a practical work of this kind, unnecessary to enter upon the discussion of the different theories which, upon this subject, have occupied the minds of naturalists, and which have resulted only in the maintenance of opposite opinions. Which was the country where the animal was first brought into a state of subjection, is another unsettled point. Colonel Hamilton Smith, notwithstanding his extensive researches, seems to have felt the difficulty of this one, and to have abandoned it in a sentence which appears to indicate a slight sentiment of despair at the futility of his labours. "We know," he says, in the twelfth volume of the Naturalist's Library, "so little of the primitive seat of civilisation, the original centre—perhaps in Bactria, in the higher valleys of the Oxus, or in Cashmere, whence knowledge radiated to China, India, and Egypt—that it may be surmised that the first domestication of the post-diluvian horse, was achieved in Central Asia, or commenced nearly simultaneously in several regions, where the wild animals of the horse
form existed."* Quitting, therefore, these regions of probability, we approach those of greater certainty when we enter upon the fields of the scientific geologist. Here, from discoveries that have, in almost every country of the habitable globe, been made, remains of the horse have been found imbedded in the strata of the earth, in juxta-position with those of other animals. In all the continents of the Old World, vestiges of his bony structure have been exhumed, mingled not only with those of animals which are, now, known to have had an antediluvian existence, but with those of the bear, the deer, the elephant, and the tiger, in every latitude between the extremes of climate. Geological researches in the New World have been attended with similar results; so that the supposition of Colonel Smith, that "the post-diluvial horse commenced nearly simultaneously in several regions," may, we think, be taken as a theory, which, at least, has probability to support it. There is hardly a district in Great Britain in which equine remains have not been discovered: and when we consider this almost universal distribution of the animal, and further consider his tractability and his adaptation to the manifold purposes for which he is used in a state of domestication, we behold a striking evidence of the beneficence of the Creator to man—"the quintessence of dust"—in placing, so readily, within his reach the noblest of quadrupeds, and amongst the most easy to be rendered subservient to his power.

"Fossil remains," says Colonel Smith, "of the horse have been found in nearly every part of the world. His teeth lie in the Polar ice, along with the bones of the Siberian mammoth; in the Himalaya mountains, with lost, and but recently ascertained, genera; in the caverns of Torquay, Ireland; and in one in

* If Eastern tradition is to be considered of any value, Armenia—the mountainous region of the Minni—ought to be viewed as the region where the first post-diluvial horses were located. This country lies at the eastern extremity of Asia Minor, occupying an extent of about 300 miles from north to south, and about 430 from east to west. As it lies on the borders of the Caucasus and Mount Taurus, it is extremely mountainous, which would render it unfavourable for the breeding of large numbers of horses; but it has numerous plains and valleys, although of greater elevation than those of southern and western Asia. In the east it is highly fertile, and is the original country whence some of our finest fruits have

stance in Barbary, completely fossilised. His bones, accompanied with those of the elephant, rhinoceros, tiger, and hyena, rest by thousands in the caves of Cronstadt, in Sevron, at Argenteuil; with those of the mastodon in the Val d'Arno; and on the borders of the Rhine with the colossal urs. All the remains hitherto discovered, appear so perfectly similar in their conformation to the domesticated horse, that they can scarcely be ascribed to other species of the genus. From the commixture of their remains, there cannot be a doubt that they have existed together with several great pachydermata. But what is most deserving of attention is, that while all the other genera and species, found under the same conditions, have ceased to exist, or have removed to higher temperatures, the horse alone has remained to the present time, in the same regions, without, it would appear, any protracted interruption; since, from the circumstances which manifest deposits to be of the earliest era, fragments of its skeleton continue to be traced upwards, in successive formations, to the present superficial mould."

Commencing with the earliest period in which mention is made of the horse, we find, that in Judea, horses were, till the days of Solomon, very rare. The earliest indirect notice of him is in the book of Genesis, xxxvi. 24; where it is said of Anah, the son of Zibeon, that he found mules in the wilderness, as he was feeding the asses of his father. The mule being the offspring of the ass and the horse, it is evident that wild horses, at all events, had then an existence in the wilderness of Idumea or Soir, which is the spot to which reference is made. The earliest direct evidence of the existence of the animal, is in Genesis xlvii. 17, where Joseph is said to have given the Egyptians "bread in exchange, com, such as the apricot and the plum. In the warmer districts, almonds, figs, and pomegranates are cultivated; and here, according to tradition, Noah and his family settled on leaving the Ark. It is now divided into fifteen provinces; the central one of which is called Ararat, where rises the mountain of the same name, on the summit of which the Ark rested after the Deluge. In Armenia and Persia, it is still designated the Kubi Nuh—The Mountain of Noah. As horses, no doubt, formed a portion of the live-stock of the patriarch, here the first post-diluvial pair must have been located, to be in accordance with the Oriental tradition, which, even down to our own time, prevails in Armenia.—Eu.
for their horses." In the very minutely detailed enumeration of the cattle stores of Abraham, Isaac, Esau, Laban, Job, &c., though there is a superabundance of other quadruped property, no mention whatever is made of horses. Neither in the fourth or tenth commandments are horses noticed with the other working animals. In the enumeration, however, of the Egyptian cattle property affected by the murrain, they are mentioned in precedence of the rest: "Behold the hand of the Lord is upon thy cattle which is in the field, upon the horses, upon the asses, upon the camels, upon the oxen, and upon the sheep."

In Deuteronomy, chap. xvii. 16, Moses forbids the Israelites, in the event of their electing from among themselves a king, to allow him "to multiply to himself horses;" and thereby foster a lust of dominion and belligerent propensities; at the same time also creating, what the Lawgiver wished much to prevent—too frequent a communication with Egypt. In the Psalms of David, we find—

"A horse for preservation is
But a deceitful thing."—Psalm xxxiii. 17.

And in Eccles. x. 7, "I have seen servants on horses." Of Dan, Jacob says, on his death-bed, that, "he shall be a serpent by the way, an adder in the path, that biteth the horse's heels, so that his rider shall fall backwards." By this time, it is evident that the horse is now tamed and reduced to perfect subjection, for he is ridden.

From whatever country the horse was derived, Egypt was undoubtedly, in the most early times, his great breeding-place. The Old Testament proves this by many references; and Colonel Smith says, that to "Egypt we appear to be indebted for the first systematic attention for reviving and improving the breeds of horses. Numerous carved or outlined pictures represent steeds, whose symmetry, beauty, and colour, attest that they are designed for high-bred types." At Jacob's funeral in Judea, there came forth, from Egypt, "chariots and horsemen a very great company." The Hebrews were pursued into the Red Sea by Egyptian horsemen; horse and rider being there overwhelmed: and Pharaoh "took 600 chosen chariots, and all the horses and chariots of Egypt, and all the horsemen, and pursued the Israelites to the Red Sea." Solomon, several centuries afterwards, obtained all his horses from Egypt. This monarch had 1,400 chariots, and 12,000 cavalry; and stalling for 40,000 horses. With this testimony, the account given by the Greek writers concurs. According to them, Sesostris (or Sesonchosis, as others write his name) was the first who taught men to tame horses and to ride them.*

In Solomon's days, the price of a single horse from Egypt was 150 shekels, which, according to Bishop Cumberland's calculation of the shekel, is about £17 10s. of our money; a great sum in those times.

In this inquiry, the next in order, after the Egyptians, are the Assyrians, who became the celebrated cavaliers of the ancient world. These people are repeatedly alluded to by the Jewish prophets, not only as excelling in the beauty of their horses, and the skill of their horsemen, but also in all the showy ornaments of equestrian garniture. Their proficiency, however, in this branch of art, did not take place till long after the Egyptians had invented it, and attained to some degree of excellence in its manipulation. Then the Medes, Assyrians, and Persians, being possessed of more gold and silver than the Egyptians, decked and bespangled the animals they rode, with blue, with purple, and with gold. Persia latterly became most renowned for its horse-riding, and clothed its horsemen most gorgeously. Xenophon says, however, that, before the age of Cyrus, that country had, from its want of wealth, or its mountainous character, no horses; but that, after his time, from the personal example, encouragements, and recommendations of their king, every man in Persia rode on horseback.†

* The achievements of this monarch are supposed to have been the labours of several kings, attributed by Egyptian priests to Sesostris alone, whose very existence is a matter of doubt. Be this as it may, however, there is no date, perhaps, in the whole range of profane chronology, more disputed than that of the age in which he is said to have ascended the throne. Various epochs have been assigned, with a difference between them of nearly 600 years: 1618, 1308, and 972 n.c., have all been given as the periods of his rule.—En.

† In the history of Cyrus, furnished by Xenophon, it is said that this sovereign was the son of Cambyses, king of Persia, by Mandana, the daughter of Astyages, king of the Medes. Conformably to the Persian educational curriculum, he was trained to endure every kind of privation, exposure to hardships, constant and laborious
So universal was this the practice, that it is understood that the very name of Persia, by which, ever afterwards, that country became known, was taken from Peresh—a word in Chaldee and Hebrew; signifying a horseman. Both in the plains of Assyria and Persia, vast numbers of horses were reared. We read in some authors, of no less than 150,000 feeding on one vast plain near the Caspian Gates. The ancient Persian horse was esteemed a gift of the highest value. Alexander the Great considered the present of one, the noblest that could be made. That this animal was one of great beauty, is unquestionable. Vegetius says—The Persian horses surpassed other horses in the pride and gracefulfulness of their paces, which were so soft and easy as to please and relieve, rather than fatigue the rider. Their pace, it seems, was as safe as it was pleasant; and when they were bred on a large scale, they constituted a considerable part of their owner’s revenue. The Nysæan horses, which the kings of Persia used in their expeditions, were celebrated as the finest in the world.

About 500 years before the birth of Christ, Darius undertook his expedition against the Scythians—a people possessing neither towns nor fields, but living, like the modern Tartars, in movable camps, upon the milk and flesh of their numerous herds. The country of this people was nothing more than a rude waste, including, with Tartary, most of the present empire of Russia. They therefore had nothing valuable to lose with an enemy, because they had nothing to defend; and their force consisted entirely of cavalry. Here, then, in this barbarous region, the horse seems to have been completely subjugated, and to have formed the principal strength of the Tartars in repelling an invasion of their territory. Notwithstanding the excellence of the Persian cavalry, Darius was forced to retreat; and, before he reached the Danube, suffered great loss and hardship. When Xerxes, the succeeding Persian monarch, and son of Darius, invaded Greece, he had 80,000 horse; which, with his 1,700,000 foot, took him seven days and seven nights to cross the Hellespont. In northern Africa, in Mauritania, Libya, and Numidia, horses were numerous; but they are described as having been slightly made, and requiring little or no attention from their owners. Passing into Arabia, there is no mention whatever made by ancient writers of the horses of this country; and it was not till the later periods of the Jewish monarchy that they became numerous in Palestine. Indeed, generally speaking, Asia Minor had no ancient celebrity for its horses, with the exception of the country around Colophon, between Ephesus and Smyrna, where there was a strong and accomplished cavalry. This force was deemed invincible; and was frequently employed as mercenaries by other nations, when engaged in war.

Passing into Europe, we find that, in Greece, the art of riding the horse, and most probably the arrival of the animal himself, did not long precede the Trojan war. This country lies between the thirty-sixth and forty-first degrees of northern latitude, and is surrounded by seas, except upon the north, where it is bounded by Epirus and Macedonia. Its original inhabitants were Pelasgians, of whose origin but little is known, but whose tribes are supposed to have extensively settled in both Europe and Asia. The early inhabitants of Greece, however, are not so much to be distinguished by their respective localities as by their several tribes; for it is found, that as circumstances required, most, if not all of them, migrated from one place to another. The Pelasgi, however, chiefly occupied the Peloponnesus (now the Morea), from which they ramified into Thessaly and other parts. They Merodach, the successor of Nebuchadnezzar, and regent of Babylon, who had wantonly invaded the territories of Astyages. In this war, his conduct was marked by such wisdom and valour, that he materially promoted the success which attended the Median army. After this, he returned to Persia, and remained with his father till he was forty years old, when he was recalled to Media, to undertake the military command under his uncle Cyaxares, who was only one year older than himself.—Ed
were the most powerful of all the tribes, and were found in all parts of Greece. From this circumstance, the whole country was, at one time, called Pelasgia.

From a period previous to the Trojan war, Grecian fable has transmitted to posterity the story of the Centaurs—semi-human horses and semi-equine men, as Ovid calls them—which warrants the inference that horses had then first made their appearance in Thessaly, the most northern province of Greece—comprising an extensive vale of singular fertility, and encompassed on every side by the lofty ridges of Olympus, Ossa, Pelion, Æta, and Pindus. It was to the people of this country that the name Hellenes—afterwards adopted as the general designation of those whom we, from the Latin, call Greeks—was applied, and who early attained to great power. They must have enjoyed some degree of consideration before the Trojan war; for Chiron, their chief, was the preceptor of Achilles. They must also, however, have been ignorant of the picture represented by that of a man and a horse when engaged in the act of riding and being ridden; for, as the Mexicans did, when they first beheld the Spanish cavalry, the Thessalians fled, panic-stricken at the sight of the double-shaped, incomprehensible monster that charged them. This is the origin of those mythic absurdities which the genius of Greek sculpture has transmitted to future ages, chiselled, by the most accomplished art, upon their marble tablets. It is surmised that these Centaurs were a tribe of Pelasgi, or emigrants from Phrygia and the southern shores of the Euxine Sea, which were occupied, at an early period, by a colony of Egyptians, planted there by Sesostris in his Phrygian and Scythian expedition. Corroborative of this supposition is the Grecian tradition, recorded by antiquaries, that Phylere, the mother of the Centaurs, cohabited with Saturn in Philyreis, an island near the southern shore of the Euxine; and that, from that island, she emigrated to Thessaly and the mountains of the Pelasgi.

Mr. Youatt, in his able treatise on the horse, offers another interpretation, by which the origin of these monsters may more naturally be accounted for. "The Thessalians," says he, "were the pride of the Grecian cavalry. Before the other provinces of Greece were scarcely acquainted with the name of the horse, their subjugation of him was so complete, that, in the language of Shakspeare—

"These gallants

Had witchcraft in't—they grew into their sense;
And to such wondrous doing brought their horse,
As they had been incorpored, and demi-natured
With the brave beast."

This power of adhesion to the back of the horse, however extraordinary, and however astonishing to the Bard of Avon, has not been confined only to the ancients. Mr. Dunn, in his History of the Oregon Territory, and in his description of the Half-breeds of that country, lets us into the secret as to how this power is obtained, and how he has witnessed it exercised in North America. "The Half-breeds," says he, "are a well-informed race, and the men are remarkably ingenious, athletic, and vigorous. In horsemanship they are singularly adroit: nor is this to be wondered at; for, in fact, they have been trained from their extremest youth to the management of the horse, accompanying their parents generally in their trapping excursions on the plains and hills, on horseback. One of these practised 'Half-breeds' would receive applause from Alexander of Macedon himself, or the best-tutored equestrian at Astley's. He would mount the boldest and most high-mettled Bucephalus of the plains; give him full play over level and rough, high and low, river and hill, until he brought him back as tame as a mouse. The cleverest fellow of this school I ever saw, was Joseph McLoughlin,* a natural son of the present governor and a half-bred woman. He was a person of some little distinction from the accident of his birth, independently of his astonishing equestrian capabilities. In seeing his feats when managing a wild stallion that galloped and plunged to desperation—clinging to the animal as if he were an inseparable part of him; playfully tossing his bare head over the upcared head of the horse; while his breech clung to his back with the tenacity of wax, and his heels seemed glued to his ribs, with his hands fastened in his mane—he completely explained to me the fabulous stories of the Centaurs; for I at once saw that there was some ground for the old fictions of poets and painters in drawing a compound animal, man and horse."

* The name seems to denote either Irish or Scotch origin.
Continuing our history regarding the probable migrations of the horse, we might trace, even from the few data afforded by history, his circuit, with the consequent art of equestrian exercise, from Egypt (the original and central riding-school of the world), into Greece and into Europe. His probable route, however, was from Egypt into Assyria and Persia; from Assyria to Cappadocia, Amazonia, and Pontus; which, on the river Thermoden, was also the residence of the Amazons. In these countries horses were most reared and most admired; and holding the highest position among the lower species of animated nature, they were offered up as sacrifices to the sun. From Pontus they passed, with the streams of westward-rushing population, to Phrygia and the southern banks of the Propontis; and thence, with "horse-taming" Pelops and the Pelasgi, they migrated into Thessaly, where, as already observed, with their novel and terrifying appearance, they confounded the simple aboriginal inhabitants.

Even at the time of the Trojan war (1192 B.C.), it is believed that horses were but rare animals in Greece, and were possessed only by princes or great men, who kept them more for the purposes of display and chariot-drawing, than for use. In the Iliad there are only two references made to horse-riding, and but one in the Odyssey. The first is where Ulysses and Diomed capture the horses of Rhesus, and ride them into the Grecian camp. The second is where a horseman is exhibited as riding on four fair coursers, and performing some of the feats which were the common stock of Astleyan representations on the south side of Westminster-bridge. In the Odyssey the reference is made in the form of a simile, which compares Ulysses, after his shipwreck, bestriding a beam of wood, to the resemblance of a man astride on horseback.

In these ancient times, the art of shoeing the horse with iron had not been discovered; so that a strong hoof, "hard as brass," and solid "as the flint," was reckoned one of the good qualities of a steed. In Oriental countries, the dryness of the roads rendered this fortification of the hoof less necessary; and the muddy ways, and miriness of the ground’s surface in the north of Europe, we suppose, first caused and confirmed the practice. Hanni-
civilisation in the arts could make it. At a later period, we find both the bit and the bridle introduced into Grecian sculptures. Neptune made the Romans first to teach "with bits the generous horse to tame." The saddle is a comparatively modern invention; and we have no notice of the stirrup until about the middle of the 12th century of the Christian era. It, however, was in use a century prior to this period; for, in the Bayeux tapestry, which was the work of the wife of William the Conqueror, the figure of a horse appears, with saddle, bridle, and stirrups. The more ancient heroes made no use of artificial means for the purpose of mounting their steeds. Their agility enabled them to fling themselves upon the backs of their animals with the utmost ease; but those who fought on horseback with the lance or spear, usually had a loop or a cord depending about two feet from the bottom of the shaft, or a small projection on the shaft itself, by either of which they could assist themselves into their seats if necessary. The horse was sometimes trained to kneel, when his rider was going to mount him; and, as ease and efficiency further impaired the agility of men, short ladders came into use for the purpose of scaling their horses' backs. Great men had their slaves to assist them both to mount and dismount; and, subsequently, that all who rode might be accommodated with the means of easily getting upon their horses in situations where other sorts of assistance could not be procured, the local magistrates of both Greece and Rome had proper stepping-stones set up, at convenient distances along the roads. In earlier times, however, it was not as a ridden, but as a war-chariot animal, or as an animal for show, that the horse was principally used. Subsequently his speed came to be publicly tested in competing for the prize at the Olympic games, founded in honour of Jupiter. Here, in the chariot races, his qualities were put to a severe test. The Olympian festival was instituted 776 years before Christ; and consisted of sacrifices to Jupiter and Hercules, and in the exhibition of contests to their honour. Every fourth year was the period appointed for the recurrence of the celebration, and an olive garland was the only prize of victory in the different exercises. This, however, became a distinction greatly envied; and the interest taken in the contests, coupled with the sanctity and splendour of the religious ceremonies, brought together an immense concourse of spectators, and distinguished it beyond all the other institutions of a similar kind established in Greece. Not till the twenty-third Olympiad was the horse introduced into the contest; and not till the twenty-fifth as a chariot-racer. The description of the chariot-racing is thus given by Mr. Youatt:—

"The chariots were arranged abreast of each other at the starting-post—for it will appear that these gave some important advantages—having been previously decided by lot. An altar was erected on one side, upon which stood a brazen eagle, dedicated to Jupiter, and a dolphin sacred to Neptune. At a signal from the presiding officer, the eagle, by some mechanism, sprang into the air; the dolphin sank under the ground, and away the horses started. The hippodrome, or course, was about one-third of a mile in length; and at the further end was a pillar, round which the chariots were to be driven, and back again to the starting-place, six times—making rather more than four miles.

"The rounding of this pillar was the first test of the skill of the driver and the docility of the horses, and many an accident happened there. This dangerous spot was no sooner passed, than the competitors came at once upon a strange figure, placed to try the courage and nerve of the horses. It was an enormous statue, called Taraxippus, the terror of the horses; and, according to old writers, well worthy of the name. None of them describe this strange deity; but all agree that he used sadly to frighten the steeds, and often to endanger their lives, and also the life of the driver.

"A little further on was a lofty rock, in the very centre of the course, leaving only a very narrow defile, in the passing through which the skill of the charioteer was severely tried; while several men placed on the rock, increased the confusion and the terror of the horses, by the continual braying of their trumpets.

"As may be well supposed, the number of the competitors was much diminished ere the conclusion of the race. Some ran against the
pillar; others were frightened out of the course by the horrible statue; and not a few were wrecked on that fearful rock. Some were destroyed on the spot; others who escaped without serious injury, were derided by the spectators on account of their want of skill; and the fragments with which the course was covered, rendered almost every step perilous."

The conqueror in such a race, says Pausanias, well deserved the crown which he received, and the honours which were bestowed upon him.

The moral as well as the physical characteristics of the horse, have, from the earliest times, formed the subjects of poetical admiration and enthusiasm. This is especially the case when he is viewed as mingling, undismayed, in the heat of the fray—pawing the ground, distending his nostrils, dilating his eyes, and erecting his ears when he hears the braying of the trumpet, or the clashing of arms at no great distance from where he is standing. As the war-steed alone, he is thus sublimely depicted in the Book of Job:—"Hast thou given the horse strength? Hast thou clothed his neck with his beautiful mane? Canst thou make him afraid as the grasshopper? The glory of his nostrils is terrible. He paweth in the valley, and rejoiceth in his strength. He goeth on to meet the armed men. He mocketh at fear, and is not affrighted. Neither turneth he his back from the sword. The quiver rattleth against him, the glittering spear and the shield. He swalloweth the ground with fierceness and rage: neither believeth he that it is the sound of the trumpet. He sayeth among the trumpets ha! ha! and he smelleth the battle afar off, the thunder of the captains and the shoutings."

Job was an inhabitant of that country from which our English breed has been so much improved by the importation of horses from the desert; and this description of the animal, under the influence of a noble excitement, is not less remarkable for its accuracy than for its lofty poetical tone. In the nineteenth verse of the Scriptures, the Hebrew word is translated as signifying "thunder;" but it also signifies the mane of the horse. Accordingly, we have substituted the natural feature of the animal for the hyperbolical and unmeaning attribute of "thunder," with which his neck is said to be clothed, but which is quite inappropriate, if not altogether absurd, in the significance of its application.

In estimating the qualities necessary for war-horses, much depends upon natural disposition. Those of a fretful temper being proverbially soft, and not generally to be depended upon, would be ill-suited for the "tented field," and this does not seem to have escaped the observation of our greatest of dramatists. Such horses are made by him to symbolise false friends. Thus he makes Julius Caesar exclaim—

"Hollow men, like horses, not at hand,
Make gallant show, and promise of their mettle;
But when they should endure the bloody spur,
They fall their crest, and, like deceitful jades,
Sink in the trial."

Homer, on the other hand, always speaks of the horse with admiration, and considers him as by nature invested with great dignity. In his conception, an additional respectability is conferred, even upon his princes and his war-grooms, by the titles which he bestows upon them of "horse-tamers" and "horse-whippers"—epithets which, however honourable in days of remote antiquity, are, in ours, associated only with the persons and the mean employments of groom of the stable and horse-jockeys. It was the practice of ancient poets, as well as of people generally, to dilate upon the beauty and majesty of their horses; to invest them with attributes of the loftiest description, and to place them in situations in accordance with these high ideas. In this, it must be confessed they were, to a great extent, justified, not only by the noble shape and gallant appearance of the animal, but by his singular disposition, and, consequently, high price; his being the friend and, as it were, the attendant of princes; the terrible, yet graceful, accompaniment of war; and never seen, as in modern times, degraded to the familiar, yet far more useful purposes of draught in our streets, and husbandry in our fields. In Grecian fable, as well as in Grecian mythology, he is also represented in the most imposing situations and attitudes. Proserpine is carried off by Plautus in a chariot drawn by four horses. Neptune, swift as light, strikes the earth with his trident, and the first-born horse rushes forth from its centre. Aurora ushers in the light of the
morning by being represented as drawn by four milk-white horses in a rose-coloured chariot. These are all striking evidences of the might and majesty possessed by the horse in the Grecian mind, and of the noble purposes for which they believed him to have been ordained. The chariot of the Sun is, in Ovid's beautiful fable of Phaeton, drawn by grey-footed steeds; and Erecboinus, a prince, is by profession, a horse-breaker. In the third Georgic of Virgil, his wonderful performances are thus immortalised:—

"Bold Erecboinus was the first who joined
Four horses for the rapid race designed,
And o'er the dusty wheels presiding sat:
The Lapithæ to chariots add the state
Of bits and bridles; taught the steed to bound,
To run the ring, and trace the airy ground;
To stop, to fly, the rules of war to know,
T'obey the rider, and to dare the foe."

A modern reader, therefore, must enter somewhat into the sentiments and feelings of antiquity, in order to perceive the beauty or propriety of Theocritus's comparison of Helen to a horse, or of Solomon's likening his love "to a company of horses in Pharaoh's chariots." The light in which the horse is thus considered as an ornament of royalty, or an appendage of war—not only ornamental, but efficient—is explanatory of many passages scattered over the pages of the Old Testament, and of those of the Greek and Latin Classics.

In the days of Xenophon, 600 years later than those of Solomon, the price of a good horse was about 50 denars, or £27 12s.; at least, such was the price paid by Sennethes, the Thracian, to Xenophon, for the steed whereon he rode during his retreat from Babylon. As this general was a skillful horseman, as well as a good judge of a horse, it is interesting to see the opinions which, in his age, prevailed respecting the points of that animal.

"The first thing which ought to be looked at," says he, "is the foot; for as a horse would be of no use, though all the upper parts of it were beautiful, if the lesser parts of it had not a proper foundation—so a horse would not be of any use in war if he had tender feet, even though he should have all other good qualities; for his good qualities could not be made any valuable use of. Thick hoofs make a horse's foot better than thin ones; and it must not be forgotten to see whether the hoofs are high or low, and near the ground both before and behind. The pasterns, or bones immediately above the hoofs and below the fetlocks, ought not to be straight like those of a goat, for this would shake the rider; and such legs are more subject to inflammation: nor ought these bones to be too low, for the fetlock would be chafed and ulcerated if the horse were ridden over ploughed grounds or among stones. The bones of the legs, being the supporters of the whole body, ought to be large; not, however, too thick with veins. The thighs, under the shoulders, are both strong and graceful when they are large; and when the chest is also large, it greatly contributes, not only to the beauty and strength of the horse, but to his being able to continue a long time in one pace. The neck should proceed from the chest, and it should be free about the bend of the head, which should have a small cheek. The eyes should stand well out; the nostrils be wide, and the ears small. The loins should be broad and short; the hanches large and fleshy, and such as to correspond with the sides and chest of the animal."

Such is the description of Xenophon; to which we may add that of Blundeville, who thus speaks of the Greek horses:—"The horses of Greece have good legs, great bodies, comely heads, and are of a high stature; and very well made forward, but not backward, because they are pyn-buttocked. Notwithstanding, they are very swift, and of a bold courage. But of all the races in Greece, both the horses and mares of Thessaly, for their beauty, bigness, bounty, and courage, of all authors, are most celebrated. For which cause, Xerxes, on his coming into Greece, made a running of horses in chariots, to be proclaimed only in Thessaly, because he would have his own horses to run with the best horses in Greece. Julius Caesar, being dictator of Rome, knowing the courage of these horses, was the first that ordained them as a spectacle before the people, to fight with wild bulls, and to kill them."

After the Greeks, the Romans followed pretty much in the same path, in reference to the management of the horse. Chariot and horse-races were, at an early period, introduced among them; and down to the reigns of
the Caesars, the young men belonging to the equestrian order were enthusiastically devoted to horsemanship. They performed, in the field, similar feats to those which the modern exhibitor executes in the circus-ring: vaulting off and on; picking up things from the ground; stretching themselves on the backs of the animals; standing upright; and leaping from one horse to another, were amongst their favourite exercises. This people invented the curb bit, and were the first to employ veterinary surgeons to attend their horses. To each of their legions horse-surgeons were attached. But after the overthrow of the empire in the fifth century, we lose all trace of any progress having been made in the management and treatment of the horse, whether in a state of health or disease.

CHAPTER II.

HORSES OF DIFFERENT COUNTRIES.

THE HORSE OF EGYPT.

Egypt being the country where, it is generally supposed, the horse was first reclaimed, necessarily takes priority in treating of the different breeds of that animal as described by travellers and others, who have had opportunities of making observations upon their forms, and testing their qualities in their native climates. This country was, in the earliest ages, distinguished by its culture, and has a length of about 600 miles, with a varying width. From Syene to Cairo, a distance of about 500 miles, its great valley is about eight miles in breadth; while, in the Delta, it widens, and adds to the extent of the country about ninety or a hundred miles. It has two great divisions, named Lower and Upper Egypt. The first comprises that portion of territory which lies between Cairo, the Mediterranean Sea, the Isthmus of Suez, and the Libyan Desert, on the north, and has Grand Cairo for its capital. The second extends from Cairo to Assouan, or Syene, and holds within its area the ruins of ancient Thebes and Dendera. The river Nile is the special glory of this country, watering and fertilising it to an extent which makes it, even at the present time, as fruitful as it was in that of Joseph—"There is corn in Egypt," having become a proverbial expression to denote plenty. This river rises in Abyssinia, traverses Nubia and Egypt, and, after a course of about 2,000 miles, enters the Mediterranean. Like most of the African rivers within the tropics, it annually overflows its banks; and thus, in a land where rain seldom or ever falls, fulfills all the purposes which a luxuriant vegetation demands for the promotion of its growth. The rise commences about the 17th of June, or near the summer solstice: by the middle of August it reaches half its greatest height; and, towards the end of September, attains its maximum, when the waters begin to subside. The fields, on which a rich sediment has been left, are then sown with all sorts of grain; and, in an amazing short space of time, the face of the whole country is variegated with plants of every hue, and with the rapidly-ripening corn. As the fertility of the country may be said almost entirely to depend upon the inundations of the river, their progress is anxiously watched and measured by a pillar, called a Nilometer. This instrument consists of a thin column or pillar, placed about the middle of the river, on the point of an island called Rhoda, between Cairo and Geeza. It has twenty divisions of twenty-two inches each; and its height is thirty-six feet eight inches. When the river has risen to the proper height, all the canals connected with the Nile are opened, and the whole country laid under water.
The domestication of the horse, in this country, took place very early; and as he was then used principally as a war animal, or perhaps for the ornamental purposes of a state pageant, he must have been well kept and properly attended.

The modern animal, however, has immensely degenerated. He is no longer the noble quadruped which the poet delighted to describe as the companion of princes; yet, under the vigorous government of Mehemet Ali, in 1821, a veterinary school was established at Abou-Zabel, of which we have an account in the 7th volume of the Veterinarian. The degeneracy of the Egyptian horse arose chiefly from the oppressive system which the Turks long pursued, in forcibly taking from the population any valuable animals they happened to have, and appropriating them themselves, without giving, in return, the slightest remuneration.

Mr. Wilson—speaking of the corps of the Mamelukes, the body-guard of the Bey—in his Expedition to Egypt, says—"Although these horses seldom pass out of a foot-page, except for a gallop of a hundred yards, most of them are foundered; and none, if quickly trotted ten miles, would be able, from want of wind and stamina, to go further." The shape of the animal, too, is neither prepossessing nor engaging. Burehardt says that he is ugly and coarse, bearing a stronger resemblance to the cart-horse than to the racer. He is frequently to be found with a short thick neck, and thin legs and knees. His head is, occasionally, fine; but the same writer declares that he never saw good legs in an Egyptian horse. Nor are the race capable of bearing much fatigue in any situation; but they are possessed of impetuosity sufficient to render them very desirable as cavalry horses; and it is upon this quality alone, that any celebrity which they enjoy is founded.

The physical features of Egypt are by no means unfavourable to the production of a beautiful breed of horses. The country consists mostly of a long and narrow vale, on each side of the Nile; bounded by parallel ridges of hills and mountains, and covered with a rich vegetation, in the highest degree congenial to the nature of the horse. The Delta—lying between the two extreme branches of the Nile and the sea, and taking its name from its triangular shape, resembling that of the fourth letter in the Greek alphabet—is the broadest and the most fertile part; and presents a fine region for successfully rearing the animal. Here he might roam at will; and, in the days of old, as he "increased and multiplied," he supplied other countries with his kind for the purposes of war. It is a remark-
able fact, however, that although there was a mounted cavalry in Egypt, and, as already observed, that Solomon's horsemen were mounted on trained Egyptian animals, there is but one representation of a man on horseback in the whole range of the sculptured and painted antiquities of that country.

In the Adventures of Giovanni Finati, the following anecdote is given of an Arab robber, who, when the Mamelukes were in Egypt, had taken a fancy to the horse and the robe of one of their Beys:—

"When some of the Mamelukes were encamped about Minich, a thief set his mind upon carrying off the horse and wearing apparel of one of their Beys; and, with this intention, contrived, in the dead of the night, to creep unperceived within the tent, where, as it was winter, embers were burning, and showed the rich clothes of the Bey lying close at hand. The thief, as he squatted down by the fire, drew them softly to him, and put them all on; and then, after filling a pipe and lighting it, went deliberately to the tent door, and tapping a groom, who was sleeping near, with the pipe end, made a sign to him for the horse, which stood piquetted in front. It was brought; he mounted and rode off. On the morrow, when the clothes of the Bey could not be found, no one could form a conjecture as to what could have become of them, until the groom, on being questioned, maintained to his fellowservants, that their master was not yet returned from his ride! and told them how he had suddenly called for his horse in the night; which, at last, seemed to give some clue to what had really happened. Upon this, the Bey, anxious to recover his horse, as well as curious to ascertain the particulars, ordered it to be published abroad, that, if the person who robbed him would, within two days, bring back what he had taken, he should not only be freely pardoned, but should receive also the full value of the animal and of the suit of clothes.

"Relying on the good faith of his promise, and possibly, too, not a little vain of his exploit, the Arab presented himself, and brought his booty. The Bey also, on his part, punctually kept his word; but since, besides the loss, there was something in the transaction that placed the Bey in rather a ludicrous light, it went hard with him to let the rogue depart so freely, and he seemed to be considering what he should do. Whilst thus resolving, and in order to gain time, he kept continually asking, over and over again, fresh and more circumstantial accounts of the manner in which the stratagem had been conducted: but the other was too crafty not to perceive that no good was preparing for him, and began to feel anxious to get safe out of the scrape. He showed no impatience, however, but entered minutely into every detail, accompanying the whole with a great deal of corresponding action; at one time sitting down by the fire, and making believe as though he were sily drawing on the different articles of dress, so as to throw the Bey himself, and all who saw and heard him, into fits of laughter. When he, at last, came to what concerned the horse, 'It was,' he said, 'brought to me, and I leaped upon his back;' and so in effect filings him-self again into the saddle, and spurring the flanks sharply with the stirrup-irons, he rode off with all the money that he had received for the animal, in his pocket, and had got much too far, during the first moments of surprise, for any of the bullets to take effect that were fired at him in his flight; and nothing further was ever heard of him or the horse."

The animal of the Bey was, no doubt, of a better quality than are the generality of Egyptian horses, or the speed of the robber would have relaxed soon enough to have allowed him to have been overtaken by that of some of the others that joined in the pursuit.

THE BARB.

Proceeding from Egypt along the northern coast of Africa, we enter the states of Barbary, which are understood to comprise the Mauritania, Numidia, Africa Proper, and Libya of antiquity. These, in succession, answer to the modern Morocco, Algiers, Tunis, and Tripoli—states which formerly seemed to constitute one great political confederacy, though regulating their internal policy and government entirely independent of each other. Barbary derives its modern name from Bar, a desert; and is divided into two parts by the Atlas mountains, which extend from east to west, and are intersected by deep and beautiful valleys. This, then, is the country
of the horse known as the Barb. Its original country is Arabia; and it was brought into Africa by those Arabs who either voluntarily left their country, or were driven from it by force of arms. The true animal is found in Morocco, Fez, and Tripoli, and is described by Berenger as seldom exceeding fourteen and a-half hands high. He further says that the countenance is indicative of spirit, though frequently rounded, and, in this particular, presenting a marked distinction to that of the Arabian. The ears are pointed and small, but occasionally they are to be found long and drooping. The crest is generally fine, but prominent, and not overlaid with mane. "The neck is of a good length; the shoulders flat and oblique; the withers prominent, and the chest almost invariably deep; the back is moderately curved, and the carcass somewhat round; the arms and thighs are muscular, and strongly marked; the knee and hock are broad and low-placed; the back-sinews singularly distinct, and well-marked from the knee downwards; the pasterns rather long; the feet firm, and but moderately open at the bars." The croup, as compared with the Arab, is said to be a little too long; but the quarters are muscular and well developed. The Barb has vastly contributed to the beauty and excellence of the horses of the Iberian peninsula; and when higher qualities in the horses of Great Britain were anxiously sought, the Barb was introduced, and has been the means of greatly improving the racing blood of this country. In Africa mares are never ridden, but always stallions—a practice just reversed in Arabia. The reason for these national peculiarities is obvious. The Arab is almost always at war; and as the stallion neighs whenever it smells the stale of the mare, this would frequently be the means of alarming his enemies when secretly approaching their encampments during the night, in his predatory expeditions. The African pursues a different mode of warfare from this. He trusts to the superiority of his force or skill; fights by day; and therefore rides the animal that he deems best adapted to carry him safe through his enterprises, whatever may be the danger in which these may involve him.

Bruce, in his African travels, observes, that "the best African horses are said to be descended from one of the live on which Mahomet and his four immediate successors fled from Mecca to Medina, on the night of the Hegira." But this must be taken as an Oriental fiction, rather than as a statement of sober truth. The affection of the Arab for his horse is so strong, that there is no origin, however noble, to which, so far as breed or race is concerned, he would not assign him. D'Arvieux describes the lamentations of one Ibrahim Abou Vouasses, over a favourite mare of noble race which he had parted with, and which he frequently made a journey to Rama to see. "He would embrace her, and wipe her eyes with his handkerchief, and rub her with his shirt sleeves, and would give her a thousand blessings during whole hours that he would be talking to her. 'My eyes, my heart, my soul!' would he exclaim, 'must I be so unfortunate as to have thee sold to many masters, and not be able to keep thee myself? I am poor, my gazelle. You know well enough, my sweet, that I have brought thee up like a child. I never beat thee, never chid thee, but did cherish thee as the apple of mine eye. God preserve thee, my dearest! Thou art beautiful, thou art sweet, thou art lovely. God defend thee from the evil eye.' And so he would go on saying a thousand things like these; he then embraced her, kissed her eyes, and went backwards, bidding her the most tender adieux."

THE ARABIAN HORSE.

It is not a characteristic of either the English or the Scotch mind, to indicate any
affection which they may have for their horses in such generous expressions of endearment as mark those of the poor Arab; yet few can read the touching narrative which Mungo Park gives of his parting with his horse, the worn-out associate of his adventures, in the wilds of Africa, without entering largely into his feelings, and deeply sympathising with his forlorn and destitute condition. “Early in the morning,” says he, under the date of July 29th, “my host observing that I was sickly, hurried me away, sending a servant with me as a guide to Kea. But though I was little able to walk, my horse was still less able to carry me; and about six miles to the east of Modiboo, in crossing some rough clayey ground, he fell; and the united strength of the guide and myself could not place him again upon his legs. I sat down for some time beside this worn-out associate of my adventures; but finding him still unable to rise, I took off the saddle and bridle, and placed a quantity of grass before him. I surveyed the poor animal as he lay panting on the ground, with sympathetic emotion; for I could not suppress the sad apprehension, that I should, myself, in a short time, lie down and perish in the same manner, of fatigue and hunger. With this foreboding I left my poor horse, and with great reluctance I followed my guide on foot along the bank of the river until about noon, when we reached Kea, which I found to be nothing more than a small fishing village.” The horse, however, did not die, but was restored, and Park had the great gratification of once more hearing him neigh on his return to Modiboo.

Major Denham, another celebrated African traveller, also laments the death of his horse. After telling us that the animal had carried him from Tripoli to Mourgouk and back again, and also over the whole journey from Tripoli to Bourou, he thus philosophises:—

“There are situations in a man’s life in which losses of this nature are felt most keenly, and this was one of them. It was not grief, but it was something very nearly approaching to it; and although I felt ashamed of the degree of deprangement which I suffered from it, yet it was several days before I could get over the loss. Let it, however, be remembered, that the poor animal had been my support and comfort—may I not say my companion?—through many a dreary day and night; had endured both hunger and thirst in my service with the utmost patience; so docile, that he would stand still for hours in the desert while I slept between his legs, his body affording me the only shelter that could be obtained from the powerful influence of a noon-day sun; he was the fleetest of the fleet, and ever foremost in the race.”

In the Biographical Sketches of Horses, by Captain Brown, we find recorded the following interesting description of a Barb and his rider at the Cape of Good Hope:—“I should have found it difficult to give credit,” says Mr. De Pages, “had what I am now about to relate not happened at this place, on the evening of my arrival there (Cape of Good Hope), and had I not been an eye-witness of those vehement emotions of sympathy, blended with admiration, which it had justly excited in the mind of every individual at the Cape. A violent gale of wind setting in from the north-north-west, a vessel in the road dragged her anchors, was forced on the rocks, and bulged; and while the greater part of the crew fell an immediate sacrifice to the waves, the remainder were seen from the shore, struggling for their lives by clinging to the different pieces of the wreck. The sea ran high, and broke over the sailors with such amazing fury, that no boat whatever could venture off to their assistance. Meanwhile a planter, considerably advanced in life, had come from his farm to be a spectator of the shipwreck. His heart was melted at the sight of the unhappy seamen; and knowing the bold and enterprising spirit of his horse, and his particular excellence as a swimmer, he instantly determined to make a desperate effort for their deliverance. He alighted, and blew a little brandy into his horse’s nostrils; when, again seating himself in the saddle, he instantly pushed into the midst of the breakers. At first, both disappeared; but it was not long before they floated on the surface, and swam up to the wreck; when, taking with him two men, each of whom held by one of his boots, he brought them safe to shore. This perilous expedition he repeated no less than seven times, saving the lives of fourteen individuals; but, on his return the eighth time, his horse being much fatigued,
and meeting a most formidable wave, caused him to lose his balance, and he was overwhelmed in a moment. The horse swam safely to land, but his gallant rider, alas! was no more."

Whilst giving a description of the horse's services in this dangerous undertaking, we regret the writer has not rescued from oblivion the name of its gallant rider. The exploit of the horse becomes the more prominent feature in this description; but without any wish to decry the merits of this noble animal, we think, in justice to its rider, who fell a sacrifice to his humanity, an effort should have been made to preserve the name of the man who had performed such repeated acts of heroism. The colony was at this time in the possession of the Dutch; and, we believe, a vessel was named after the rider, and a pillar ordered to be erected to his memory. The local authorities, however, with the proverbial meanness of little minds, refused to bestow upon the son a trilling place which had been filled by his generous father.

THE DESERT HORSE, AND SWIFT HEIRIES
OF AFRICA, Etc.

As we proceed towards the west coast of Africa, the Barb is said to improve both in form and gracefulness of action; but deep in the Sahara desert, there is a species called the "wind-sucker, or desert horse"—a description of which, in conjunction with that of the heiries, will now occupy our attention. Mr. Jackson, in his account of Morocco, says, that the skrubach errech, or desert horse, is to the common horse what the desert camel is to the camel of burden; the only difference between them in point of feeding is, that this horse requires a portion of camel's milk every day; if it cannot get this, and is obliged, from hunger, to eat barley and straw, particularly when first brought to Morocco, it falls away. However, it gradually recovers, fills up, and becomes handsome to the sight, but loses all its former speed, so that it is afterwards employed to hunt ostriches, at which sport it is very expert. To the Arabs of the desert, the chase of the ostrich is the most attractive and eagerly sought of the many aristocratic diversions in which they indulge; and the training through which the horse passes, previous to the sport, is rather hard. Seven or eight days before the intended hunt, they are entirely deprived of straw and grass, and fed on barley only. They are only allowed to drink once a-day, and that at sunset—the time when the water begins to freshen: at that time also they are washed. They take long daily exercises, and are occasionally galloped, at which time care is taken that the harness is right, and suited to the chase of the ostrich. "After seven or eight days," says the Arab, "the stomach of the horse disappears; while the chest, the breast, and the croup remain in flesh: the animal is then fit to endure fatigue." They call this training techaka. The harness used for the purpose in question is lighter than ordinary, especially the stirrups and saddle, and the martingale is removed. The bridle, too, undergoes many metamorphoses; the mountings and ear-flaps are taken away, as too heavy. The bit is made of a camel rope, without a throat-band, and the frontlet is also of cord; and the reins, though strong, are very light. The period most favourable for ostrich-hunting is that of the great heat; the higher the temperature, the less is the ostrich able to defend himself. The Arabs describe the precise time as that, when a man stands upright, his shadow has the length only of the sole of his foot.

Each horseman is accompanied by a servant called zemmar, mounted on a camel, carrying four goat-skins filled with water, barley for the horse, wheat-flour for the rider, some dates, a kettle to cook the food, and everything which can possibly be required for the repair of the harness. The horseman contented himself with a linen vest and trousers, and covers his neck and ears with a light material called haeuli, tied with a strip of camel's hide; his feet are protected with sandals, and his legs with light gaiters called trobog. He is armed with neither gun nor pistol, his only weapon being a wild olive or tamarind stick, five or six feet long, with a heavy knob at one end.

The exact position of the ostriches being known, the plans are arranged; the horsemen divide and form a circle round the game at such a distance as not to be seen. The servants wait where the horsemen have separated, and as soon as they see them at their posts, they walk right before them; the ostriches fly,
but are met by the hunters, who do nothing at first but drive them back into the circle; thus their strength is exhausted by being made to continually run round in the ring. At the first signs of fatigue in the birds, the horsemen dash in—presently the flock separates; the exhausted birds are seen to open their wings, which is a sign of great exhaustion; the horsemen, certain of their prey, now repress their horses; each hunter selects his ostrich, runs it down, and finishes it by a blow on the head with the stick above mentioned. The moment the bird falls, the man jumps off his horse, and cuts her throat, taking care to hold the neck at such a distance from the body as not to soil the plumage of the wings. The male bird, while dying, utters loud moans, but the female dies in silence.

When travelling in the desert on these horses, as well as on the heirie, or desert camels, the bowels of the riders become relaxed by the time they have arrived at the end of their journey. They are then forced to take a draught of camel's milk, which being rejected by the stomach, they drink again. This second draught is, after a longer time, also rejected; when a third is taken, by which time the tone of the stomach is generally restored to be capable of retaining the beverage, which is converted into nourishment.

Although hardly coming within the legitimate province of our subject, yet in speaking of the "wind-sucker," we deem it necessary to make a few observations on the heirie, of which he is a frequent companion in the desert.

This animal is, in figure, similar to the common camel of burden, but more elegantly formed. The Arab, with his loins, breast, and ears bound round, to prevent the percussion of air proceeding from a quick motion affecting him, rapidly traverses, upon the back of this abstemious quadruped, the scorching desert, the fiery atmosphere of which parches, and almost impedes respiration, to such an extent as nearly to produce suffocation.

The motion of the heirie is violent, and can be endured only by those patient and hardy Arabs who are accustomed to it. These riders will make a journey of three days almost without food—a few pipes of tobacco, or a handful of dates, serving to supply their necessities.

With a bakul, or goat-skin, a porous earthen vessel filled with water, a few dates, and some ground barley, the Arab travels from Timbuctoo to Tafilelt, feeding his heirie but once, at the station of Arzawad; and this camel, on an emergency, will abstain from drinking seven days. In general, he has a ring put through the upper lip, to which is fixed a leathern strap, answering the purposes of a bridle; the saddle is similar to that used by the Moors, or what the mountaineers of Andalusia make use of.

The swiftness of the heirie is thus figuratively described by the Arabs:—"When thou shalt meet a heirie, and say to the rider 'Salem Alie' (peace be unto thee), ere he shall have answered the salutation, he shall be nearly out of sight; for the swiftness of his camel is like the wind."

The most inferior kind of heieres are called Talatayee—a term expressive of their going the distance of three days' journey in one. The next kind is called Sebayee—expressing an animal that goes seven days' journey in one; and this is their general character. There is also one called Tasayee, or the heirie of nine days; but this species is extremely rare.

THE NUBIAN OR DONGOLA, AND ABBYSSINIAN HORSES.

Nubia, or Dongola, lies to the south of Egypt, and has, on the east, the Red Sea; on the west the Desert; and is bounded on the south by Sennaar. The Nile is also its great river, and the date is the principal fruit of the country. The low shrub of the Senna is abundant, and the climate is considered healthy in general. Here there is said to be a breed of horses distinct from any other which either Africa or Arabia produces. Ludolph, who passed through this country in the 17th century, says, that the horses are spirited, powerful, and active, and mostly of a black colour; that they are used for the chase and for war; and that they are not fatigued by travelling long journeys, for the labour of carrying or drawing loads is put upon mules. The appearance of this animal is mostly described as especially noble and majestic. He is usually well-caparisoned; and although the colour is generally black, yet there are to be found some of them bay and sorrel. Bruce, the Abyssinian traveller, speaks of the Nubian
horse in the following terms:—"What figure the Nubian breed of horses would make in point of swiftness is very doubtful, their form being so entirely different from that of the Arabian; but if beautiful and symmetrical parts, great size and strength, the most agile, nervous, and elastic movements, great endurance of fatigue, docility of temper, and, beyond any other domestic animal, seeming attachment to man, can promise anything for a stallion, the Nubian is, above all comparison, the most eligible in the world. Few of them are less than sixteen hands high."

Bosman, another traveller, describes the Nubian horse as the most perfect of his kind; and says that, in 1816, one of them was sold in Grand Cairo for a thousand pounds. Several of the species have been introduced to England, but with what results we have been unable to ascertain.

The Abyssinians, according to Bruce, destroy the elephant for food. "They cut the whole of the flesh off his bones into thongs, like the reins of a bridle, and hang these, like festoons, upon the branches of trees, till they become perfectly dry, without salt; and then they lay them up for their provisions in the season of the rains." This traveller has given an animated description of an elephant hunt, conducted by the Africans, who, on such occasions, are greatly assisted by their spirited horses.

"An hour before day, after a hearty breakfast, we mounted on horseback, to the number of about thirty. But there was another body, both of horse and foot, which made hunting the elephant their particular business. These men dwell constantly in the woods, and know very little of the use of bread, living entirely upon the flesh of the beasts they kill, chiefly that of the elephant and rhinoceros. They are exceedingly thin, light, and agile, both on horseback and foot; are very swarthy, though few of them are black; none of them woolly-headed, and all of them have European features. They are called agagcer, a name of their profession, not of their nation; which comes from the word agar, and signifies to hamstring with a sharp weapon. More properly it means the cutting of the tendon of the heel, and is a characteristic of the manner in which they kill the elephant, which is shortly as follows:—"

"Two men absolutely naked, without any rag or covering at all about them, get on horseback; this precaution is for fear of being laid hold of by the trees or bushes, in making their escape from a very watchful enemy. One of these riders sits upon the back of the horse, sometimes with a saddle, and sometimes without one, with only a switch or short stick in one hand, carefully managing the bridle with the other; behind him sits his companion, who has no other arms but a broadsword. His left hand is employed in grasping the sword by the handle; about fourteen inches of the blade is covered with whip-cord. This part he takes in his right hand, without any danger of being hurt by it; and, though the edges of the lower part of the sword are as sharp as a razor, he carries it without a scabbard."

"As soon as the elephant is found feeding, the horseman rides before him as near his face as possible; or, if he flies, crosses him in all directions, crying out, 'I am such a man and such a man; this is my horse, that has such a name. I killed your father in such a place, and your grandfather in such another place; and I am now come to kill you. You are but an ass in comparison of them.' This nonsense, he verily believes, the elephant understands, who, chased and angry at hearing the noise immediately before him, seeks to seize him with his trunk or proboscis; and, intent upon this, follows the horse everywhere, turning and turning round with him, neglectful of making his escape by running straight forward, in which consists his only safety. After having made him turn once or twice in pursuit of the horse, the horseman rides close up alongside of him, and drops his companion just behind on the off side; and while he engages the elephant's attention upon the horse, the footman behind gives him a drawn stroke just above the heel or what in man is called the tendon of Achilles. This is the critical moment; the horseman immediately wheels round, takes his companion up behind him, and rides off at full speed after the rest of the herd, if they have started more than one; and sometimes an expert agagcer will kill three out of one herd. If the sword is good, and the man not afraid, the tendon is commonly entirely separated; and if it is not cut through, it is generally so far divided, that the animal, with the stress he puts upon it, breaks the remaining part asunder. In either
case, he remains incapable of advancing a step till the horseman's return, or his companions, coming up, pierce him through with javelins and lances; he then falls to the ground, and expires with loss of blood.

"The agager nearest me presently lamed his elephant, and left him standing. Ayto Engedan, Ayto Confu, Guebra Marran, and several others, fixed their spears in the other before the agager had cut his tendons. My agager, however, having wounded the first elephant, failed in the pursuit of the second; and being close upon him at the entrance of the wood, he received a violent blow from the branch of a tree which the elephant had bent by his weight, and, after passing, allowed it to replace itself, when it knocked down both the riders, and very much hurt the horse. This, indeed, is the great danger in elephant-hunting; for some of the trees, that are dry and short, break by the violent pressure of so immense a body moving so rapidly, and fall upon the pursuers, or across the road. But the greatest number of these trees bend without breaking, and return quickly to the former position, when they strike both horse and man so violently, that they often beat them to pieces."

**THE ARABIAN HORSE.**

Arabia has been considered, by some naturalists, the original country of the horse, but upon what grounds it is not so easy to determine. It has already been shown that Solomon received all his own horses from Egypt; and those which he sent to the sovereigns of Phoenicia, he also procured from that country. Even so late as the second century of the Christian era, there is a record extant, showing that horses were among the articles exported from Egypt to Arabia; and, in the seventh century, when Mahomet attacked Koreish, near Mecca, he had no more than two horses in his whole army. Such circumstances speak strongly against the assertion that the horse is originally Arabian; for if he were so, it is difficult to account for his scarcity in a country which, of all others, ought to have been the most natural for his rapid propagation. At what time the Arabs began to employ him is not very clear. At all events, from the facts just given, it must have been at a comparatively late era. Where they obtained their breed, it is likewise impossible accurately to determine. In our opinion, Arabia is more likely to have been supplied from the Egyptian stock, rather than from that of any other land; for if, in the days of Solomon, the Arabian horses had been distinguished, that monarch would have supplied his stables with, at least, a few of them, for the mere purposes of display, if for nothing else. Taking into account the physical features of Arabia, we should think it is not very favourable for rapidly increasing the breed of horses. Designated, in its three great geographical divisions, as the Stony, the Desert, and the Happy, it has been compared to a coarse garment with a rich border. In its centre it presents nothing more than a dreary plain of sand, alike destitute of water and vegetation—marked only by the tracks of caravans. A chain of mountains runs along the west to the Arabian Sea on the south; but it has no river of a magnitude sufficient to make it important. The few streams which wander over the country are generally absorbed by the sandy tracts they pervade, and decrease in volume during their progress to the sea. The mountains are few, and its climate is sultry. Vegetables of every description are scarce. The coffee shrub, planted on terraces in the form of an amphitheatre, grows to perfection; and the date, the tamarind, and the orange, also flourish: but horses neither drink coffee, nor eat tamarinds or oranges; and hence are more likely to have had their origin in a country much better adapted by nature to their wants than Arabia seems to be. Burckhardts says that the tribes richest in horses, are those who dwell, during the spring of the year at least, in the fertile plains of Mesopotamia; for, notwithstanding all that is said of the desert horse, plenty of nutritious food is absolutely requisite for its reaching its full vigour and growth. The numerous tribes in the Red Sea, between Akab and Mecca, them, the Arabs thinking that much liquid affects the wind, as well as mars the proportions of their favourite animal, and renders him less beautiful to look upon.
and especially those to the south of Mecca, as far as Yemen, have very few horses, but the Kurds and the Bedouins, in the east, and especially in Mesopotamia, possess more horses, and more valuable ones, than all the Arabian Bedouins put together; for the richness of their pastures easily nourishes the colts, and fills the studs. "The number of horses in Arabia," he adds, "is not more than 50,000—a number far inferior to that found in any part of Europe or Asia, on an equal extent of ground."

According to the same author, there are in Syria, at the present day, three breeds of horses—the true Arab breed, the Turkman, and the Kourdy; the last being a mixture of the two former. From the superior size, and more martial appearance of the Turkman horse, he makes a splendid figure when dressed in Turkish trappings; and, on this account, is, by the Osmanlis, preferred to the Arab horses. They are trained to walk with great grace; to start suddenly off at full speed; to turn with the gentlest touch, and to stop short instantaneously. The Arab horse is more hardy, more beautifully limbed, and much fleeter than the Turkman; but he is more slender, and less strong in his appearance. The esteem in which the Arab holds his animal, however, has no counterpart in any other country. The Rev. V. Monro, in his Summer's Ramble in Syria, when on a visit to the river Jordan, says, that "one of the Arab escort, a great ruffian, was mounted on a white mare of great beauty; her large fiery eye glanced from the edge of an open forehead, and her exquisite little head was finished with a pouting lip and expanded nostrils; her ribs, thighs, and shoulders, were models of make, with more bone than commonly belongs to the Syrian Arab; and her stately step received additional dignity from the manner in which she took it; whilst the carriage of her tail gave the infallible indication of good family. Having inquired her price, I offered the sum; whereon the dragoon asked one-third more. After much abating and debating, I acceded; and he immediately stepped back in the same proportion as before. This is invariably the practice with the Arabs; I, therefore, discontinued my attempts to deal. The Arab said he loved his mare better than his own life; and that, when mounted upon her, he felt rich as a pasha. Shoes and stocking, he had none; and the net value of his dress and accoutrements might be calculated at something under seventeen-pence sterling."

M. De Chateaubriand, upon what authority we know not, records an instance of reciprocal affection between an Arab horse and his master; which, if it be not of pure invention, has seldom, if ever, been paralleled.

An Arab and his tribe had, with complete success, attacked in the desert the caravan from Damascus; and when the Arabs were occupied in packing their booty, the horsemen of the pasha of Acre, who had come to meet the caravan, rushed suddenly on the robbers, and killed a considerable number of them, and made others prisoners. Having tied these with cords, they took them to Acre, as presents to the pasha.

Abon el Massel, the hero of this predatory attack, had received a ball in his arm during the engagement; but as his wound was not mortal, the Turks had fastened him upon a camel, and took his horse along with him.

The evening of the day of their approach to Acre, the party encamped with their prisoners upon the mountain of Safhadt. The legs of the wounded Arab were tied together by a leathern belt, and he was laid near the spot where the Turks slept. Kept awake, during the night, by the pain of his wound, he heard his horse neigh among others picketed round the tents, according to the Eastern custom. Recognising his voice, he could not resist the desire to see once more the former companion of his life. Accordingly, with great difficulty, he managed to crawl on his hands and knees to his steed. "My poor friend," said he, addressing the animal of his affections; "what canst thou do among these Turks? Thou wilt be imprisoned under the roof of a khan, with the horses of an aga or pasha. The women and children will no longer bring thee the camel's milk, or barley, or doura in their palms. Thou wilt no more course the desert, like the wind from Egypt. No more wilt thou divide, with thy chest, the refreshing waves of Jordan. O that, though I remained a slave, I could at least set thee free! Let me try! There, go! return to our tent; tell my wife that Abon el Massel returns..."
to it no more, and lick the hands of my four children."

Thus speaking, Abon had, with his teeth, gnawed the goat's hair which had served to fasten the Arab horses, and the animal became free. Seeing, however, his master manacled and bound at his feet, the faithful and intelligent creature seized his master by the leathern girdle round his body, set off at a gallop, and carried him to his tent. Arriving there, and letting him drop on the sand, at the feet of his wife and children, the horse expired from fatigue.

The whole tribe wept his loss; poets sang his merits; and his name is constantly in the mouths of the Arabs who inhabit the country about Jericho.

If this is not a fiction, truth is certainly much more strange than romance; but, in this country, we have but a slight idea of the degree of attachment and intelligence, which the habit of living with the family, of being caressed by the children, fed by the women, and encouraged or chided by the voice of the master, adds to the natural instinct of the Arabian horse. The breed of the animal has, naturally, a higher intelligence than belong to the horses of our island, arising, perhaps, more from the constancy of their companionship or association with man, than from any extraordinary endowments which nature has bestowed upon them.

The same author tells us, that when he was at Jerusalem, there was a Bedouin, who, on being pursued by the governor's guards, rushed on his mare from the top of the hills that overlook Jericho. The animal secured, at full gallop, down a declivity, without stumbling, leaving his pursuers lost in astonishment and admiration. The poor mare, however, dropped down dead on entering Jericho; and the Bedouin, who would not quit her, was taken, weeping over the body of his faithful companion.

"This mare," continues Chateaubriand, "has a brother in the desert, who is so famous that the Arabs always know where he is, what he is doing, and how he does."

It is generally believed that many Arabs preserve the pedigrees of their horses; and that there are five noble breeds, each of which they deduce from one of the five favourite mares of Mahomet. These five races, however, diverge into innumerable ramifications; and any mare of superior excellence may be the original of a new breed, the descendants of which are called after her. "On the birth of a colt of noble breed, it is usual to assemble witnesses, to write an account of its distinctive marks, with the name of its sire and dam. These genealogical tables never ascend to the grand-dam, because it is presumed that every Arab of his tribe knows, by tradition, the purity of the whole breed. Nor is it always necessary to have such a certificate; for many horses and mares are of such illustrious descent that thousands might attest the purity of their blood. The pedigree is often put into a small piece of leather, covered with a waxed cloth, and hung by a leather thong round the horse's neck."

In Weston's Fragments of Oriental Literature, the following pedigree—much longer, and, no doubt, far nobler than that alluded to by the Laird of Cockpen, as belonging to his Scotch sweetheart—was found hanging round the neck of an Arabian horse, bought by Colonel Ainslie, during the Egyptian campaign of the British against the French, at the commencement of the present century:

"In the name of God, the merciful and compassionate, and of Saed Mahomed, agent of the High God, and of the companions of Mohammed, and of Jerusalem. Praised be the Lord, the Omnipotent Creator."

"This is a high-bred horse, and its colt's tooth is here in a bag about his neck, with his pedigree, and of undoubted authority, such as no infidel can refuse to believe. He is the son of Rabbamy, out of the dam Labadah, and equal in power to his sire: of the tribe of Zashalah; he is finely moulded, and made for running like an ostrich. In the honours of relationship, he reckons Zaluah, sire of Mahat, sire of Kallaq, and the unique Alket, sire of Mnashe, sire of Alsheh, father of the race down to the famous horse, the sire of Lahalah; and to him be ever abundance of green meat, and corn, and water of life, as a reward from the tribe of Zashalah; and may a thousand branches shade his carcase from the hyæna of the tomb, from the howling wolf of the desert; and let the tribe of Zashalah present him with a festival within an inclosure of walls; and let thousands assemble at the rising of the sun in troops hastily, where the tribe holds up under a
canopy of celestial signs within the walls, the saddle with the name and family of the possessor. Then let them strike the bands with a loud noise incessantly, and pray to God for immunity for the tribe of Zoab, the inspired tribe."

At the birth of an Arabian colt it is never permitted to fall to the ground, but is caught in the arms of those who are waiting beside the dam, washed, and as tenderly handled as if it were destined to become a distinguished member of the human family. At the end of a month it is weaned, and then, for a hundred days, it is nourished with camel's milk. After this time it is allowed a little wheat, which is increased by degrees, while the milk continues to form the largest portion of its aliment. This mode of feeding continues for another hundred days, when the foal is sent forth to pick a little of the herbage that may be growing round the tent of its owner. Some barley is also given; and, if the Arab can afford it, a little camel's milk in the evening. All this while it, with its dam, inhabits the same tent as the Bedouin and his family, who are to be found, much more frequently, lying with, or rolling upon the mare and her foal, than upon their own natural parents. Thus the animals grow kind and gentle. In the constant habit of receiving good treatment, their tempers are never ruffled; and the caresses which, from the moment of their birth, are bestowed upon them, they continue to return by every means in their power. This characteristic of the Arab horse is thus referred to by Bishop Heber, who, in his Narrative of a Journey through the Upper Provinces of India, says that he was in the habit of riding a little Arabian animal:—"My morning rides are very pleasant. My horse is a nice, quiet, good-tempered little Arab, who is so fearless, that he goes, without starting, close to an elephant; and so gentle and docile, that he eats bread out of my hand, and has almost as much attachment and coaxing ways as a dog. This seems the general character of Arab horses, to judge from what I have seen in this country. It is not the fiery, dashing animal I had supposed, but with more rationality about him, and more apparent confidence in his rider than the majority of English horses." A French authority, in giving his own personal experience of the Arabs and their horses, says, that Arabian horses in general come from Nedgid, and are commonly called Nedji. A more noble race is called Kohloni—divided into five different families, or noble Cherifs. These five races, as we have already observed, are the supposed descendants from the five blessed mares of the prophet, and are named Tonaissse, Gilphe, Manegine, Sedie, and Seclawe. Besides these, there are a number of other families too difficult to enumerate. It must be owned that there are no certain signs by which one can ascertain whether a horse is a Nedgid or a Kohlan; for "I have conversed," says he, "with many intelligent Arabs, who all assured me that they could not distinguish them unless the origin of the dam was known to them. For these reasons they kept their mares unstained by the leap of an inferior stallion, which is considered one of the principal sins in the Koran; and, as this is an injunction imposed upon them by their religion, they preserve it rigidly. If by chance the contrary should happen, the Bedouin does not value the foal the least; and however handsome and promising it may be, he will part with it for a mere trifle. If a Kohlan mare is stamina to a Nedgid stallion, the foal is a Kohlan; but if only to a Genesidek, the foal also is only a Genesidek; and a foal only of a Nedgid mare by a Kohlan stallion, is Nedgid. This being the case, among the latter, many horses will be met with as handsome as the first, although of an inferior race; but even the Arabs cannot distinguish them with out knowing the race of the dam."

Although it is generally asserted that the Arabs keep a stud-book, our French authority denies this to be the case; and he further says that they do not call together a number of witnesses when the covering act is performed, or when the foal is born: all this is false; "for," he continues, "I have often had opportunities to observe a leap in the night, where scarcely any, and but casual witnesses were present." This, however, might casually be the case; although, generally, where purity of breed is to be anxiously kept, veracious witnesses might be called in to testify satisfactorily to the birth. According to our authority, the mode of proceeding among the Arabs to procure a foal, is to choose the best
horse among their own or neighbouring tribe
for a covering stallion, which they travel about
with, as Europeans do; and it is very difficult

to purchase him, at least during the covering
season. The horse serves three mares daily
at about one Spanish dollar each, and travels
from tribe to tribe, at times to a great distance.
They allow their horses to cover as early as
two years old; and frequently the mares are
not older. It happens, however, that not
unfrequently they are worthless at three or
four years old. Stallions, mares, and foals
graze all together.

The Arab generally rides without a bridle:
a halter, with a nose-band covered with iron
like a cavesson, serving him instead. In lieu
of a saddle, his noble coursers has only a piece
of wadded linen, with two napes for stirrups,
tied on his back; and, as in many parts of
Germany, he seldom has the hind feet shod.

The many scars seen on Arabian horses,
have been caused by firing, which is much
practised, as a remedial agent, in cases of
disease. Many of the horses—even two-year
olds—are disfigured by scars above and beneath
the fetlocks, which at first might be taken
for splints, but which originate from the iron
manacles by which they are fastened to prevent
them being stolen, to which they are much
exposed from their being, during the whole of
the day, left out grazing, and at times suffered
to stray from the camp to a considerable
distance. At night, however, every Arab has
each animal before his tent, with one of his
legs tied, which prevents him from going far
from the spot where his master has, for the
time being, pitched his fragile abode.

Regarding the formation and shape of their
stallions, the Arabs seem to be quite indifferent.
If the animal runs well, is of the proper origin, and has no superstitious marks,
they use him as such, and will, without hesitation, put him to their best mares; but if
the origin of the most splendid-looking stallion is doubtful, and his marks ill-favoured, he would
not be put to the worst of mares. In candour
it must be owned, that though the stallions
may have great faults in point of form, they,
at the same time, have extraordinary qualities;
for as soon as they are mounted, all defects
vanish. It would be almost impossible to
detect any, so noble is their appearance.

Many stallions with ugly bind-quarters, and
with their tails set very low, appear, when they
are mounted, to carry their tails so erect, that
one might doubt whether they were the
same horses. A few of the finest horses, so
far as look goes, exhibit all the characteristics of English thorough-breds, but are
much more active and pleasant to ride, when
broken in a little after the European fashion.
When they are taken raw from the desert,
and wholly unused to bridle or spur, they
walk with terror on any paved way. They
are then difficult to be made to trot, as their
habit is to jump, at once, out of a walk into a
full gallop, and stop as suddenly; but being
very docile, they are easily broken-in properly.

The five principal races, which are said to
have originated from the five favourite mares
of the Prophet, and which only deserve the
name of Kohlan, are mostly met with at
Bagdad and Orfa. Some European judges
prefer the Nedgid to the Kohlan; but the
Oriental prejudice always returns to the
Kohlan, as its race is bred more in and in,
like our own race-horses. Although it is
difficult to say, with any sort of certainty,
whether a horse is a Nedgid or Kohlan,
yet it may be remarked that the former
has somewhat of a Roman nose and high
forehead; whilst a true Kohlan, with a
genuine certificate, has a nose drawn inwards
like a jack or pike, large eyes, wide nostrils, a
broad front, and a beautiful head. One may
buy without difficulty a stallion; but an Arab
seldom parts with a mare; and, if pressed by
necessity, he manages as follows:—First, the
price is agreed upon: the purchaser then
begins to use the mare, and the first and second
foals are delivered to the seller, who, if he likes,
haves the right to deliver, in return, one foal for
the dam. These conditions often vary; for at
times the owner will not sell above a fourth of
the mare; which, in the Arabian language, is
called purchasing one foot.

As few, if any, of our readers are likely to
visit Arabia for the purpose of purchasing
horses, seeing that a better breed now exists
in our own island, it is unnecessary to dilate
on the different tribes of desert Cheicks, who
may, and may not, be trusted in their horse-
dealing transactions with strangers. We may
observe, however, that many of the moro
superstitious Arabs are reluctant to show their horses to strangers, from a fear of the "evil eye." The dread of this superstition makes the Arab never omit offering a prayer to Mashalla for protection. Should his horse fall ill after a visit from a stranger, he immediately calls in a sort of wizard, who, after muttering some cabalistical words, breaks an egg on the front of the animal; but whatever may be the imagined efficacy of this talismanic operation, the patient not unfrequently dies; when the wizard gravely says, "God ordained it so," or "it was written so." Thus does the wizard farrier of Arabia slip out of his dilemma, yet still continues to preserve his character. A veterinary surgeon, however, would step in and administer a proper medicine to the animal; and, without the assistance of any magical nomenclature, would save the life of the horse, and smile alike at the remedial egg of the wizard, and the solemnly absurd and cabalistic mode of its application. According to European notions, even some of the prophecies of Mahomet are sheer nonsense, particularly those about colour: others coincide with observations of the present age. If Mahomet actually was inspired by Allah, our wives would do well never to permit their husbands to ride horses which carry the tail on one side, as they are sure to be soon repudiated; and maidens ought to stand in awe of bachelors on stallions which have white spots on their thighs.

No people have surpassed the ancient Arians in the tenacity with which they have preserved their ancient character and habits. In the life of the modern Bedouins, we still trace the same as that pursued by their remote ancestors, who, in the days of Moses, and in those of Mahomet, dwelt under similar tents, and conducted their flocks and camels to the same prings and pastures. Descended from Ishmael, whose hand, as we read in the Book of Genesis, was against every one, the Arab still keeps up his hostility to all men not of his race. In the desert he is a robber, and in the town he has all the vices of civilisation, without relinquishing those of the savage state. To see a horde of this nomadic people enter the desert, with their women, children, horses, camels, sheep, and goats; to see them pitch their tents, and take up their position on some green spot, amidst a sea of sand, may be deemed one of the most extraordinary episodes that can be witnessed in the great epic of human existence. M. de Portes, an eye-witness of a scene of this kind, furnishes us with a somewhat minute description of its principal features.

First appear a few horsemen on their mares, sweeping along like the wind, armed with long lances, encircling in a gallop the place where they intend to halt, and each individual choosing a particular spot, according to his own fancy. When he has done this, he immediately drives his lance in the ground, and fastens his mare to it; as much as to say, "Here shall I pitch my tent." By this time a great many more are arriving; some on horses, but most on camels; and in the distance a formidable army is seen marching up, pèle-mèle, very fast. These are their families and the bulk of the tribe, with their tents, baggage, and camels; some of the animals carrying women or children; others tents and furniture; and an innumerable host following quickly on foot. Those conveying the families are accoutred according to the wealth of the owner. The camel of the Cheick carries a sort of palanquin, in the shape of a canoe, placed at length, and open in front, that the animal may be guided in his course. This receptacle usually contains three or four women, and as many children; these last in a state of nudity. Each family now takes the direction of the lance, which it knows, and, in an astonishingly short time, a town appears to have been built. The whole locality teems with life and bustle; men are shouting and talking; women are getting things into order; whilst naked children are running about and gambolling in the water, wherever they can find a ditch.

The camp is pitched without the least regularity, only the tent of the Cheick is in the centre, and distinguished from the other tents by its larger size. All the tents are made of camel or goat-skins, without elegance or neatness, fastened by two poles six feet high. The interior is divided by a carpet, one half being appropriated by the women, the other by the men and for the reception of strangers. The furniture consists of a few carpets, straw or reed mats, which serve as a bed; but some of the poorer class sleep on the bare earth, only
covered by a habas. The most necessary utensils for cooking are striking addenda to the stock of their household "goods and chattels." These generally consist of a pot of metal; a large metal or wooden plate; a cup of zinc or wood, out of which they all drink without being cleaned; a coffee-pot of copper, and a cask fabricated of camel-skins.

Simplicity in everything is one of the grand characteristics of these nomades. In point of dress, the men wear a long wide shirt until it actually becomes rotten; nor do they ever take it off except at night, when they lie on it, only covered by a meghlas of coarse wool. They also go about barefooted. The Anaze's Arabs, however, display a little more taste. They never leave their tents unarmed; and their weapons consist of a sword, a gun, and a lance; with axes, or other offensive weapons with which they may defend themselves, or destroy those upon whom they make war.

The women are habited in a long shift of blue linen. They also draw a black veil to a knot under the nose, and let it fall gently over their bodies. This veil they often arrange in such a manner as to show a large ring drawn through the right nostril, and fastened with a chain to the temple. They are fond of exhibiting their lips, painted of a blue colour; and they have many figures engraved on the chin, cheek, nose, and neck. They never leave their tents uncovered. In height they are above the middle stature—walking nobly and gracefully, with beautiful black eyes, which they have the art of making appear larger than they really are by painting the eyelids: their noses are well formed; but the other features of their countenances are often disfigured by many different marks. Their hands and arms are always handsome; but their feet are rather broad, never having been compressed by shoes.

The children run about naked, the boys wearing only a tightly laced girdle of leather round their loins. The reason assigned for this custom is, that it makes them strong, enables them to run fast, and, by compressing the stomach, does not allow them to eat so much as they would otherwise do, if nature were left to enjoy the freedom of her own conditions. The men also wear this belt. The children are all usually finely made, none of them being hardly ever deformed. All are very hardy; capable of fighting for a whole day; suffering no injury, though constantly exposed to the excessive heat of an almost vertical sun, whilst engaged in exercising with the lance, or wrestling with each other.

The women attend to the duties of the household, and occupy themselves with weaving and spinning. The affairs of the cuisine do not take up much of their time; for although the Arabian is voracious, if an opportunity offer for him to gratify himself with something that he likes, he rarely exceeds a pilau of red rice with melted butter. To this, which usually serves for dinner, sour milk, dates, honey, duphte, &c., are, now and then, added.

The women are obliged to grind the corn, which they do by means of a rude species of primitive hand-mill. The bread is baked in flat cakes upon iron plates. The women fetch the water, which is to be procured only at times, and often at a great distance from their tents. So far as cleanliness is concerned in reference to their clothing, both sexes are alike indifferent, generally to a disgusting extent.

In a religious point of view, though excessively superstitious, they are much less devout than the Osmanlis. Many, however, observe the Ramadan; and they pray in company, ranged in one line, with a priest at their head, who has a peculiar pride in converting "the human face divine" into something as hideous as possible. Their wealth consists of camels and horses; of a few herds of sheep and goats, which yield them milk and butter; they also use camel's milk, but have no cows. The number of camels is generally very considerable—many possessing ten, twenty, and upwards; and the Cheicks sometimes owns as many as 300, of which he annually sells a considerable number to the Turco-mans, who, it is said, have been known to purchase about 2,000, at the rate of 200, and 250 Turkish piasters a-piece, from different Cheicks in the desert. The evening return of the camels to the camp affords a singular sight to a European. From 5,000 to 6,000 of these camp attendants, followed by their young ones, gambol along the barren ground like goats; and their clumsy forms partake largely of the ludicrous when they endeavour to cast off their usual gravity, and begin to frisk about with all the wantonness of a young gazelle.
During the government of the Wahabees, horses became scarcer and scarcer every year among the Arabs. Foreigners rose to be large purchasers of them, and carried them into Yemen, Syria, and Bassora, which latter place supplies India with Arabian steeds. The reason assigned for their masters parting with their animals was, that they were afraid of having them taken from them by their chiefs; for it had become the custom, on every frivolous pretext of disobedience or crime, to pronounce the most valuable Bedouin mare forfeited to the crown.

For the purchase of Arabian horses of true blood, Syria holds the highest rank in the opinion of judges; and Nauran is considered the best district, as the horse can there be purchased at first-hand, on account of the Arabs encamping there during the spring. For a person, however, pursuing the trade as a profession, Damascus would be the best place to live in. Those animals which are bought for the Indian market at Bassora, are obtained at second-hand from Bedouin dealers, who get them from the Montifell Arabs, who do not pay much attention to the preservation of purity in the breed.

In considering the characteristic features in the form of the Arab horse, there is a great deal to excite admiration. His neck is long and arched, and springs gracefully from the chest. After the head, the shoulder is superior to that of any other breed. The shoulder-blade has a beautiful backward inclination; and without the smallest indication of clumsiness, is thickly laid with muscle. The legs, though fine and small, are strong and solid. In short, every feature about him, marks his superiority, and justifies the belief in his capability of accomplishing many of the feats which have been chronicled of him.

The comparative excellences of Oriental horses are thus estimated by a writer in The Sportsman:—"Taking the comparative excellence of the different races, Nejid, between the desert of Syria and Yemen, is generally reckoned to produce the grandest, or noblest horses. Hejaz, extending along the Red Sea, from Mount Sinai to Yemen, and including in it Medina and Mecca, the handsomest; Yemen, on the coast of the Red Sea and the Indian Ocean, and the most fertile part of Arabia, the most durable; Syria, the richest in colour; Mesopotamia, the most quiet; Egypt, the swiftest; Barbary, the most profile; and Persia and Koordistan, the most warlike."

The introduction of the Arabian into England, and the influence he has had on our own racing-blood, will be noticed in another place.

THE PERSIAN HORSE.

When, in the days of antiquity, the Persian horse was considered the best for cavalry in the East, the improved Arabian breed had no existence. He is of larger growth than the Arabian, and his principal points are thus described by Berenger:—"They are, in general, small-headed; they have long and somewhat too fine foreheads, and they are rather too narrow-chested; their legs are a little small, but their groups are well-fashioned, and their hoofs good and firm. They are docile, quick, light, bold, full of spirit, capable of enduring much fatigue, swift, sure-footed, hardy in constitution, and contented with almost any provender." This is a high character; but since the time when Berenger wrote, we believe this breed has somewhat degenerated. It is this animal which figures on the Assyrian sculptures in the British Museum; and it was one of this species which Alexander the Great received and esteemed as a valuable and most acceptable present. Under the reign of Cyrus they became remarkable for the splendour of their trappings. In Sketches of Persia, by Sir John Malcolm, he says, that a variety of horses are now produced in Persia; but that the inhabitants of the districts which border on the Gulf, still preserve, in a state of purity, those races of animals which their ancestors brought from the opposite shore of Arabia. In Fars and Irak there is a mixed breed from the Arabian, which, though stronger, is still a small horse compared with either the Toorkoman or Khorassan breeds, which, by the soldiers of Persia, are most prized. Both of these latter races have a large proportion of Arabian blood in them.

Sir R. Ker Porter gives the following account of the Persian horses, and the mode in which they are managed:—

"The Persian horses never exceed fourteen
or fourteen and a-half hands high, yet certainly, on the whole, are taller than the Arabs. Those of the desert and country about Hillah run very small, but are full of bone and of good speed. The general custom is to feed and water them at sunrise and sunset, when they are cleaned. Their usual provender is barley and chopped straw, which, if the animals are piqueted, is put into a nose-bag, and hung from their heads; but, if stabled, it is thrown into a small lozenge-shaped hole, left in the thickness of the mud-wall for that purpose, but much higher up than the line of our mangers; and there the animal eats at his leisure. Hay is a kind of food not known here. The bedding of the horse consists of his dung. After being exposed to the drying influence of the sun during the day, it becomes pulverised, and, in that state, is nightly spread under him. Little of it touches his body, that being covered by his clothing—a large nummud from the ears to the tail, and bound firmly round his body by a very long surcingle. But this apparel is only for cold weather; in the warmer season the night-clothes are of a lighter substance; and during the heat of the day, the animal is kept entirely under the shade.

"At night he is tied in the court-yard. The horses' heads are attached to the place of security by double ropes from their halters, and the heels of their hinder legs are confined by cords of twisted hair, fastened to iron rings and pegs driven into the earth. The same custom prevailed in the time of Xenophon, and for the same reason—to secure them from being able to attack and main each other, the whole stud, generally, consisting of stallions. Their keepers, however, always sleep on their rugs amongst them, to prevent accident: and sometimes, notwithstanding all this care, they manage to break loose, and then the combat ensues. A general neighing, screaming, kicking, and snorting, rouses the grooves, and the scene for awhile is terrible. Indeed no one can conceive the sudden uproar of such a moment, who has not been in Eastern countries to hear it. They seize, bite, and kick each other with the most determined fury, and frequently cannot be separated before their heads and haunches stream with blood. Even in skirmishes with the natives, their horses take part in the fray, tearing each other with their teeth, while their masters are in similar close quarters on their backs."

To see a specimen of the race-running Persian horse, greatly excited the curiosity of Sir R. K. Porter. Accordingly, he went to the races; and as the sovereign was to be present, doubtless the best animals which the country could produce, had entered the lists. The contesting horses were divided into three sets, for the purpose of lengthening the sport; and they had been in training several weeks, often going over the ground on which they were to run in that time. The consequence of this was, that when the day on which they were to run came, they were so reduced in weight, that their bodies were nearly cutting the skin. The distance marked for the race was rather longer than the distances chalked out by our sportsmen at Epsom, or Newmarket, or Doncaster celebrity. It was twenty-four miles; and that his majesty might not have to wait unamused when he arrived in the field, the horses had set forward long before, by three divisions, from the starting-point—a short interval of time having been allowed to pass between each set—so that they might begin to come in a few minutes after the monarch had taken his seat. The different divisions arrived at the goal in regular order, but in such a state of fatigue and exhaustion, that their former boasted fleetness hardly exceeded a moderate canter when they passed before the royal eyes.

In almost every book of travels that we read, connected with those countries where the Arabian and his steed are found, anecdotes illustrative of that great admiration and ardour of affection which the rider has for his animal, are abundant. The following are given by Sir John Maxwell:—"An envoy had returned from his mission, and taken up his encampment near Bagdad, when an Arab, riding a bright bay mare of extraordinary shape and beauty before his tent, attracted his attention. The Arab, on being asked if he would sell her, said—'What will you give me?' 'That depends upon her age; I suppose she is past five?' 'Guess again,' said he. 'Four?' 'Look at her mouth,' said the Arab with a smile. On examination she was found to be rising three. This, from her size and
symmetry greatly enhanced her value. The envoy said, 'I will give you fifty tomans,' a coin nearly of the value of a pound sterling. 'A little more, if you please,' said the fellow, apparently entertained. 'Eighty—a hundred.' He shook his head and smiled. The offer at last came to 200 tomans! 'Well,' said the Arab, 'you need not tempt me further; it is of no use. You are a rich elchee (nobleman). You have fine horses, camels, and mules; and I am told you have loads of silver and gold. Now, added he, 'you want my mare, but you shall not have her for all you have got.'

Who can help admiring the disinterested affection of this semi-savage for his animal! Again—

"An Arab sheik or chief, who lived within fifty miles of Bussora, had a favourite breed of horses. He lost one of his best mares, and could not for a long while discover whether she was stolen or had strayed. Some time after, a young man of a different tribe, who had long wished to marry his daughter, but had always been rejected by the sheik, obtained the lady's consent, and eloped with her. The sheik and his followers pursued; but the lover and his mistress, mounted on one horse, made a wonderful march, and escaped. The old chief swore that the fellow was either mounted upon the devil, or the favourite mare he had lost. After his return he found the latter was the case; that the lover was the thief of his mare as well as of his daughter; and that he stole the one to carry off the other. The chief was quite gratified to think he had not been beaten by a mare of another breed; and was easily reconciled to the young man, in order that he might recover his mare, which appeared an object about which he was more solicitous than about his daughter."

HORSES OF INDIA AND THE EASTERN ARCHIPELAGO.

In India there seems to be a considerable variety of breeds of horses. The performances of a few of the races, whether in the point of speed or bottom, are very far from being contemptible, even when compared with some of our own. In such a climate, where every European must of necessity be mounted, it becomes of importance, for the army as well as civilians, that proper attention should be paid to the selection of the best horses to breed from. Although they are, in general, small, they exhibit all the evidences of having descended from a good stock.

The editor of *The Horse*, published under the superintendence of the Society for the Diffusion of Useful Knowledge, says—

"The Toorky, originally from a Toorkoman and a Persian, is beautiful in his form, graceful in his action, and docile in his temper. It is said that, when skilfully managed, the grandeur and stateliness of his carriage are equal to what the warmest imagination can conceive of the horse; his spirit rising as his exertions are required, he exhibits to his beholders an appearance of fury in the performance of his task, yet preserving to his rider the utmost grace, playfulness, and gentleness.

"Next comes the Iranee, well limbed, and his joints closely knit, and particularly powerful in the quarters, but with scarcely sufficient spirit, and his ears large and loose.

"The patient and docile Cozakee is deep in the girth, powerful in the fore-arm, but with large head, and sadly cat-hammed; hardly, and calculated for long journeys and severe service.

"The Mojinniss have spirit, beauty, speed, and perseverance.

"The Tazsee is slight, hollow-backed, and, for that reason perhaps, although deficient in strength, and leaving as it were his hind legs behind him, and likewise irritable in temper, yet sought after on account of the peculiar easiness of his pace."

A sale of horses, near the Company's stud, at Hissar, is thus described by an excellent judge:—"Not less than 1,000 horses were shown. They were all above fourteen hands and a-half in height, high-crested, and showy-looking horses. The great defect seemed a want of bone below the knee, which is, indeed, general to all the native horses throughout India; and also so great a tendency to fulness in the hocks, that, in England, it would be thought half of them had blood spavins."

A writer in the *Sportsman's Magazine*, expresses himself indifferently upon the qualities of the horses in the East Indies:—

"The small Maharrata horse," he says, "is an active, serviceable little beast; but, in ten cases out of twenty, extremely vicious, but will often make a capital hunter, in fact, being the only horse in India worth his keep; the larger
horses from Hindostan being adapted only for the capping of a native Souwarree. They are leggy, under-limbed, and, as far as vice goes, regular man-eaters.

"The horses from Guzerat and Cutch are certainly endowed with greater amiability of disposition, but are more calculated for purposes of display and parade than for anything else. The natives are very partial to this breed, and give long prices for them—frequently as much as two or three thousand rupees. They blow them out to an enormous size, by feeding them on a composition which must be anything but agreeable to the palate of the horse. This consists of a kind of paste, made of pounded grain and sheep's head, wherewith the poor animal is crammed like a turkey. The end of the flowing tail, generally reaching the ground, is dyed of a deep-red colour; a cruelly sharp bit is put into his mouth; he is buried under a ton of bedding covered with crimson cloth, doing duty for saddle; and, thus caparisoned, he is deemed fit to carry one of the 'pillars of the state.' It is a pretty sight to see a Souwarree, or procession, accompanied by a cavalcade thus mounted. On such occasions, the individuals forming the pageant, take every opportunity of displaying their horsemanship—a cavalier occasionally darting from the crowd at the top of his speed, and as suddenly pulling his horse on his haunches in the midst of his headlong career; then wheeling about, and still at full speed, describing, in an incredibly small space, the difficult figure of eight, with all the apparent ease of a graceful skater."

It is unnecessary to specify the excellences of some of the individual horses which have acquired celebrity in this country. It is enough to say that, generally, they have been found possessed of sufficient stoutness to carry the Mahratta warriors through the turmoil of many a hard-fought day, before their power was broken by the fall of Seringapatam, or the death of Tippoo Saib, in 1792. The Mahratta army was principally composed of cavalry; and to see a troop of them, with their knees as high as the backs of their horses; their heels firmly adhering to the horses' sides, and their hands clinging to the manes or the peaks of their saddles, is anything but a graceful specimen of horsemanship. His seat, however, is made perfectly secure by the Mahratta; for, like practice in everything else, he becomes, as it were, "to the manner born," and feels sufficiently safe in his seat to impress those who see him with the idea that he is both secure and comfortable.

Most of the horses in the East are picketed during the day, as well as during the night; and a rope is carried from each side of the head-stall, and fastened to a peg driven into the ground. To the hinder fetlocks a rope is also tied and fastened to a peg, twenty or thirty yards behind the animal. Their eyes are kept covered, and their bodies clothed in such a way as to preserve the beautiful glossy appearance of their coats.

In the caparisons of his horse the Mahratta displays the usual Oriental taste for show and magnificence. The breast of the animal is adorned with especial splendour; and numerous coins of different sizes and value are fashioned into plates, which hang and glitter from his breast, and very often form a rich booty to his conqueror. The mane is usually plaited and braided with silk, decorated with silver knobs, and terminating in a beautiful top-knot rising between the ears. Should the warrior happen to have distinguished himself against his enemies, a few curious tails, said to have been taken from the wild cow, very likely will be found hanging on each side.

With this Eastern region the imagination naturally associates everything that is vast, not only in regard to the physical features of the country, but in regard to the riches it possesses, and the undertakings of its inhabitants. Its rivers are amongst the largest in the world, and its mountain-peaks are the loftiest; its plains the most extensive, its valleys the most luxuriant, and its forests realising all "the pomp of groves" described by the poet. It is called by Milton "the gorgeous East," which showered on her kings barbaric pearl and gold; and is the country of the largest as well as the fiercest of quadrupeds. It has given to the world the most magnificent bird—the peacock—of all the feathered tribes; and has, also, in the institutions of its people, exhibited more instances of gross superstition, revolting cruelty, and deep degradation, than any land on the face of the earth. Its horses, however, are inferior to the English breed. Even its
imported Arabians succumb to the stamina of our "islanders," which are now, unquestionably, the finest animals in the world.

To the east of our Indian empire, in Burmah, Siam, and China, horses are yet of a smaller breed; and those of China are usually poor-spirited, meek, and not well made. In Moore's *Notices of the Indian Archipelago*, we are assured that, in every country lying to the east of the Burmamooter, and south of the tropic, the horse, however diversified, is little better than a pony. "This fact," says a writer in the *Museum of Animated Nature*, "after quitting Bengal, is first noticed in the countries of Cassay, Ava, and Pegu. Here the horse seldom equals thirteen hands high; but is active, spirited, and well formed. As we proceed to the south and west, the horse becomes more diminutive; and those of Lao, Siam, and the southern provinces of China, are inferior in size and beauty to those of Ava and Pegu. The Siamese and Cochin Chinese have no cavalry, and make no use of their ponies, except for riding, on ordinary occasions. Even for this last purpose they are not esteemed, the elephant being always preferred as a more respectable and dignified mode of conveyance. In the Malayan peninsula there are no plains or roads; and the inhabitants, living almost exclusively on the low and woody banks of the rivers, naturally substitute their canoes and boats for beasts of carriage and burden; and hence the horse has not yet been naturalised amongst them. Proceeding eastward in the Malayan islands, the horse first occurs in the interior of Sumatra; and here we have two of the best breeds known in those countries—the Achin and Batta, both very spirited, but small and better suited for draught than saddle.

"Of all the countries of the Archipelago, the horse is most frequent in the island of Java. The Javanese pony is generally larger than that of Sumatra, and has more the form of a horse—more temperate, and less gay and

*This is the finest and most valuable island of the Indian Archipelago, and is divided, nearly in its whole length, by a range of volcanic mountains, attaining the height of 8,000 feet above the sea. This range approaches nearest the southern coast, rising into high and rugged hills, against which the surf dashes violently; so that, with the exception of a few bays, where a landing on the island can be obtained, it is otherwise inaccessible. On the northern side of this mountain ridge the surface

handsome. Two distinct races may be described—one of the plains, and one of the mountains. The first is somewhat coarse, and sluggish in disposition, and so large as occasionally to reach the height of thirteen hands and an inch. The second is small and hardy, and, as in the case of the Kuninghan—a breed in the interior of Cheribon—sometimes very handsome, and giving great pleasure to the eye by his general appearance."

In Java the horse is used both for the saddle and as a beast of burden; but the natives never use him for agricultural purposes, or, indeed, for any species of draught. By Europeans, however, he is extensively used in carriages; and on the level and well-constructed roads of Java, four of them will draw a carriage at the rate of twelve, and even fifteen miles an hour. There is, however, no real advantage in employing this diminutive breed for such a purpose, as a pair of English post-horses, on the same roads, will go as far and as fast without the slightest difficulty. To accomplish this in a carriage of the same weight as the English horses would draw, would require twelve Javanese ponies. One horse, therefore, is equal to six ponies; and as, at the utmost, a full-grown horse will not consume above twice the quantity of food required for a pony, the charge of maintaining him, in proportion to the work he is capable of performing, is no more than one-third.

The horse, but of an inferior breed, is found on the islands of Bali and Sombolk; also in the island of Sambarra, where there are two different races—those of Samboro and Bima. The last, especially those of Gunong Api, are by far the handsomest breed of the Archipelago, and are extensively exported. Passing Sambarra, the horse is traced to Flores, Sandalwood island, and Timor; but nowhere further to the east, being unknown in the Moluccas, New Guinea, and the neighbouring islands. Next to Java,* the horse is found in greatest

is low and swampy, intersected by a great number of rivers and fine bays; where good anchorage is obtained, in moderate depth, during the south-east monsoon. The mouths of all the rivers, however, are choked up with mud or sand-banks; and when they are swelled by the torrents, they inundate all the low lands. The eastern extremity of the island is but thinly inhabited, and very little cultivated. All the European settlements are on the northern coast; but a magnificent military road, con-
abundance on the Celebes, the breed of which is, on the whole, pronounced the best in the Archipelago.

Within the Eastern Archipelago, as in other parts of the world, the colour of the horse has a singular connection with temper, quality, and locality. The prevailing colour of the Archive ponies is piebald, which becomes rarer and rarer as we proceed eastward. A Bima pony of this colour is as rarely seen as a black Arab. The prevailing colour of the Batta pony is bay and mouse-colour. In Java the best horses are those of the most prevalent colours—namely, bays and greys; the roan and mouse-coloured horses are very generally good. The worst colours are black and chestnut. The Javanese have such a dislike to the latter colour, that chestnut horses are not permitted to appear at their public tournaments. Bays, greys, and duns, are the best and most frequent colours in the Bima ponies. Blacks and chestnuts are not frequent, but they are not considered inferior. Greys and bays prevail among the ponies of Celebes and the Philippines, nearly to the exclusion of all others. In the plains of Celebes herds of wild horses exist—no doubt the descendants of a domesticated stock.

Of the speed of the Arab horses in India, we have the following account of an extraordinary match, for 1,000 rupees, which arose out of a conversation amongst several officers in one of the performances of the late Mr. Osbaldeston. The distance to be run was seventy miles in four hours and ten minutes, and the number of horses was to be unlimited.

Eleven horses, the number which it was proposed to employ in the match, were, in the course of a couple of days, mustered by the parties and their friends, and were exercised every morning on the race-course here for the short time intervening between the making and coming off of the match.

structed by the Dutch, traverses the whole length of the island. For upwards of a century the Dutch remained in undisturbed possession of Java, where, however, their rule was most oppressive and odious to the natives; but in August, 1811, a British force took by storm Batavia, their capital, and the whole colony subsequently surrendered. Under the government of Sir Stamford Raffles, whose memory is held by the inhabitants in affectionate veneration, the prosperity of the island rapidly increased. But in 1816 it was restored to its former masters.

The backers of Old Time were numerous; and, in fact, the general opinion was that the match would not be won: the grounds for which were, that the roads were known to be in a bad state; that the Bore Ghaut, a steep and winding descent of four miles, with a precipice on one side of the road, had to be passed; added to which, was the probability, nay almost certainty, of obstruction from the droves of bullocks carrying grain up the country, with which the road is usually at this season thronged. It was, moreover, supposed that the horses in training were by no means equal to the performance; and that an accident, of which there appeared more than a probability, would infallibly lose the match.

From the confidence of the parties themselves, however, the betting, at starting, was even on the match being performed in four hours ten minutes; three to two against four hours; three to one against three hours fifty minutes; and ten to one that it was not won in three hours and thirty minutes.

On the first making of the match, two watches on the chronometer principle, which had been selected for the occasion, had been placed in the hands of a watchmaker; and these having been set on the day preceding the match, one was taken on the mail to Pauwell, by the umpire, whilst the other was reserved for the start at Poona.

At a quarter past five o'clock in the morning of the day appointed for the event to “come off,” Mr. Rawlinson, riding twelve stone, appeared at the starting-place; and the word “off” having been given, the match commenced.

Only one, and that not a very large drove of bullocks, was met between Poona and Rhandalla; the distance, forty-four miles, having been performed in exactly two hours, without any accident having occurred. Here a violent horse had been injudiciously stationed; and

The population is estimated by the British surveys at more than 5,000,000. The inhabitants consist of Javanese, who inhabit the interior parts, and are in general the cultivators of the soil; Malays, Chinese, Dutch, English, and mixed castes. The Chinese are shopkeepers and traders. The Malays are altogether a servile race, and are the servants and drudges of the colonists. The Javanese are of the Hindoo family, their language being a dialect of the Sanscrit; and their religion is Mohammedanism, which they embraced about three centuries ago.
immediately on his being mounted, the curb turned round in his mouth, and he ran away with his rider the whole way down the Ghaut; but luckily was, after two or three narrow escapes, pulled up safe at Kolapoor. The last horse, when within a couple of miles of home, suddenly leapt off the road into the fields, and alighting on bad ground, fell. No injury, however, was sustained by either horse or rider, who immediately remounted, and arrived in Pauwell at twenty-eight minutes to nine o'clock—thus winning the original match with fifty-three minutes to spare.

The horse which ran between Wargnon and Carlí, was the only one of those employed in the match which had ever appeared on the turf.

The match was ridden with great nerve and judgment throughout by Mr. Rawlinson, son of Mr. Rawlinson, of Chadlington, Oxfordshire; and the horses were Arabs belonging to the officers.

THE TOORKOMAN HORSE.

Turkistan is that part of South Tartary north-east of the Caspian Sea; and has been celebrated, from early times, for producing a pure and very valuable breed of horses. They are called Toorkomans; and are said to be preferable even to the pure Persians for service. They are large, standing from fifteen to sixteen hands high; swift, and inexhaustible under fatigue. Some of them have travelled 900 miles in eleven successive days. They, however, are somewhat too small in the barrel; too long on the legs; occasionally oval-necked, and always have a head largely out of proportion; yet such are the good qualities of the animals, that one of the pure blood is worth two or three hundred pounds, even in that country.

The inhabitants of this country generally lead the same sort of life as their ancestors, being nomades, or wanderers. They dwell in tents, which are removed from place to place as their lands become exhausted and pastureage fails to supply them with their necessities, or as they themselves “increase and multiply,” and their flocks become too numerous; when, like Abraham and Lot, they separate—the one party going to the right, and the other to the left. The flesh of the sheep and the horse forms their chief article of subsistence; for, as the poet says, the Tartar first rides his horse, then eats him. To him the horse is, of all animals, the most valuable. What the camel is to the Arab, and the reindeer to the Laplander, the horse is to him the prime source of his wealth.

Captain Fraser, in his journey to Khorassan, thus relates the impression which these horses made on him:—"They are deficient in compactness; their bodies are long in proportion to their bulk; they are not well ribbed up; they are long on the legs; deficient in muscle; falling off below the knee; narrow-chested; long-necked; head large, uncouth, and seldom well put on. Such was the impression I received from the first of them, and it was not for some time that their superior valuable qualities were apparent to me."

Mr. John Lawrence says, that it is related, on the authority of a certain Prussian count, that a German prince having, with the utmost care and expense, raised a most valuable breed of horses from a son of the well-known English racer, Morwick Ball, it was one of the first imperial acts of Napoleon I. to honour the proprietor with a military order to have the whole of them marched to France, which was promptly executed.

On the same authority it is stated, that an Arabian horse was obtained in Germany (probably by the way of Turkey and Hungary), which proved superior, for the beauty, strength, and worth of the stock he produced, to any which had been before known in that country.

The name of this famous stallion was Turkmainatti, a name in equal estimation, in Germany, with that of the Godolphin Arabian in England. The valuable stock of this horse has spread over the country; and young Turkmainatti, some time, ably supported the honour of his family.

It is not unreasonable to suppose that this horse was a native of the country we have just been describing, instead of an Arabian. It is, however, from Arabian sires that the Toorkomans trace their breed.

THE TURKISH HORSE.

The Turkish horse is descended principally from the Arab, crossed by the Persian and certain other bloods. The body, however,
is even longer than the Arabian's, and the crupper more elevated. He has contributed materially to the improvement of the English breed. The Byerley and the Helmsley Turk, are names familiar to every one conversant with horses, and connected with our best blood.

Asiatic Turkey is the largest and most valuable portion of the Ottoman empire, occupying the central part of the temperate zone in the west of Asia. He has no country more interesting, and few richer in historical remembrances, whether sacred or profane. The garden of Eden is, by many topographical writers, supposed to have been situated between the point where the junction of the Tigris and the Euphrates takes place, and the Persian Gulf; hence it becomes the reputed scene of the primitive creation of man. Here, according to them, Adam and Eve were, in a state of innocence, placed.

"His fair large front and eye sublime, declared Absolute rule; and hyacinthine locks Round from his parted forelock manly hung, Clustering, but not beneath his shoulders broad; She, as a veil, down to the slender waist Her unadorn'd golden tresses wore Dishevell'd."

Both Europe and America received from this land their religion and their letters; the former from Palestine, and the latter from Phœnicia; and the principal events in the life of our Saviour, took place within its boundaries.

The inhabitants of a country so eminent in renown, and so high in arts and civilisation, must, at a very early period, have had the horse reduced to a state of domestication. Here was the Assyrian empire, one of the greatest of antiquity; and here Nineveh, its capital, was laid waste in accordance with the denunciations of the prophet Nahum. From these remote times, the Turkish horse has been a prominent object in war; and no animal has a more majestic, a more noble and brilliant appearance when carrying his rider, and exhibiting his costly caparisons.

Evelyn, the author of Sylva, thus describes one of these animals which had been sent over to England in the reign of Charles II., and which he seems to have been fortunate enough to have seen. "I never beheld so delicate a creature!" he exclaims; "somewhat of a bright bay, two white feet, a blaze; such a head, eyes, ears, neck, breast, belly, haunches, legs, pastern, and feet; in all respects beautiful, and proportioned to admiration; spirited, proud, nimble, making halt, turning with that swiftness, and in so small a compass, as was admirable." The learned and benevolent Busbequius, who was ambassador at Constantinople in the seventeenth century, is equal to Evelyn in his admiration of the Turkish horse.

"There is no creature so gentle as a Turkish horse, nor more respectful to his master, or the groom that dresses him. The reason is, because they treat their horses with great lenity. I myself saw, when I was in Pontus, passing through a part of Bithynia called Axios, towards Cappadocia, how indulgent the countrymen were to young colts, and how kindly they used them soon after they were foaled. They would stroke them, bring them into their houses, and almost to their tables, and use them even like children. They hung something like a jewel about their necks, and a garter, which was full of amulets against poison, which they are most afraid of. The grooms that dress them are as indulgent as their masters; they frequently sleek them down with their hands, and never use a cudgel to bang their sides, but in case of necessity. This makes their horses great lovers of mankind; and they are so far from kicking, wincing, or growing untractable by this gentle usage, that you will hardly find a masterless horse amongst them.

"But, alas! our Christian grooms' horses go on at another rate. They never think them rightly curried till they thunder at them with their voices, and let their clubs or horsewhips, as it were, dwell on their sides. This makes some horses even tremble when their keepers come into their stable; so that they hate and fear them too. But the Turks love to have their horses so gentle, that at the word of command they may fall on their knees, and in this position receive their riders.

"They will take up a staff or club upon the road with their teeth, which their rider has let fall, and hold it up to him again; and when they are perfect in this lesson, then, for credit, they have rings of silver hung on their nostrils, as a badge of honour and good discipline. I saw some horses, when their master
was fallen from the saddle, stand stock still, without wagging a foot, till he got up again. Another time I saw a groom standing at a distance, in the midst of a whole ring of horses; and I saw some horses, when their master was at dinner with me in an upper room, prick up their ears to hear his voice; and when they did so, they neighed for joy."

There can be no doubt that the law of kindness, constantly operating upon the horse, has the best possible influence on the disposition of the animal, and inspires him with sentiments of a correspondingly amiable description. The Turks have him so docile and tractable, that they do not hesitate to play at ball, with a golf-stick, on his back. This game is played both in Turkey and Syria, and proves the perfect state of training to which the horse has been brought, as the smallest touch of the bridle makes it wheel, gallop at full speed, or suddenly stop, as the will of the rider commands.

In Syria, and other parts of western Asia, the horse is fed upon chopped straw and barley; and of this provender a certain quantity is given morning and evening, none being supplied in the interim. "In the spring season, the horses are fed, from forty to fifty days, on green barley, cut as soon as the corn begins to ear. This is termed lying down to grass; during which time the animals remain constantly exposed in the open air; and for the first eight or ten days are neither curried, mounted, nor led about. After this they are

* Of the various tribes inhabiting Syria, some are indiscriminately found everywhere, whilst others are confined to particular sites. The Greeks proper people certain villages, and form a class of labourers for the country, and drudges for the towns. In many respects they resemble the Irish, and are, like them, "the hewers of wood and the drawers of water." The Maronites form a corps of the nation which occupies almost exclusively the territory comprised between Nahr-el-Kelb and Nahr-el-Bared, a region extending from the summit of the mountains on the east, to the Mediterranean on the west. The bordering tribes, the Druzes, occupy the space from Nahr-el-Kelb to Sour, the ancient Tyre. The country of the Metuaim comprehends the valley of Becca, as far as Sour. But this tribe is now dispersed, and likely to become extinct. As for the Aussarichs, they are scattered over the mountains of Autakieh, chiefly in the pashalie of Tripoli. The wandering or pastoral tribes abound principally in the plain of Antioch; the Kurds, in the mountains situated between Alexandretta and the Euphrates; and the Bedouin Arabs, on all the
dressed as usual, and rode out gently; but are never much worked during the grass season. Some feed the horses with cut barley in the stable-yards; but the general practice is to confine them to a certain circuit by means of a long tether, in the barley-field. This grazing is considered of great service to the health of the horse, and imparts a beautiful gloss to his coat."

Everywhere in Asia Minor, as well as in Arabia, Persia, and neighbouring countries, we meet with anecdotes which indicate, to an extraordinary extent, the affection which the natives bear for the horse. Burchardt relates a story which, whilst it places the speed and endurance of one in an eminent point of view, at the same time, shows how even an enemy will express his admiration of an animal ridden by his foe. "A troop of Druses* on horseback, attacked, in the summer of 1815, a party of Bedouins, and pursued them to their encampment; the Bedouins were then assisted by a superior force; and becoming the assailants in their turn, killed all the Druses except one, who fled. He was pursued by some of the best mounted Bedouins; but his mare, although fatigued, could not be overtaken. Before his pursuers gave up the chase, they called to him, and begged to be permitted to kiss his excellent mare, promising him safe-conduct for her sake. He might have taken them at their word; for the pledge of an Arab, in such circumstances, might have been relied on; he, however, refused. They immediately left the frontier of Syria adjacent to their deserts, and in the plains of Palestine. The nation is divided into two classes; the people, and the Cheiks or nobles. They live in the mountains, villages, hamlets, and isolated houses. The country is essentially agricultural; each inhabitant has the right over his own farm or pasturage; the Cheiks are only distinguished from the other natives by a variety in their dress. In other respects they have the same rights and privileges. Among the Maronites there are neither mendicants nor robbers, as among the Arabs; and both by day and night the traveller may pursue his course unmolested. They are monogamous; and, like the Persians, choose their wives without seeing them. Although Christians, they preserve the Arabic custom of the tahori; and the next of kin of the man assassinated, has the right of taking his revenge. According to a recent census, the Maronite population is estimated at 120,000 souls, of whom the men bearing arms amount to 30,000—a considerable population for a district measuring some 150 square miles, and abounding in rocks, and all the beauties of natural scenery.
pursuit, and blessing the noble beast, cried out to the fugitive, 'Go and wash the feet of your mare, and drink off the water.' This expression is often used by the Bedouins to show the regard they have for their mares.'

Some of the Turkish, as well as Toorkoman horses, incline to have white legs, against which there is a prejudice held by a great many English grooms—on what account we are not aware, as the celebrated horse Bucephalus, of Alexander the Great, we believe was a skewbald. A writer in the Sporting Magazine thus combats this prejudice:—"Turn to the banks of the Euphrates—to the decayed, but once splendid seats of the caliphs of the Black Banner—to the cradle of the Arabian Tales—to the Queen of the East, Bagdad, the beloved capital of the great Haroun al Rasched—and there we have a breed of horses uniting the fire of the Persian, with the symmetry and enduring qualities of the desert breed. Go further to the southward; cross the great river; roam among the settled tribes who have pitched their tents on the very verge of civilisation, near unto the great cities, the dwellings of slaves, as they are not inaptly termed by the Bedouins; and you may lay your hands on the flowing manes of a race of horses—all chestnut, with the starting prominent eye like an ember glowing, 'full of fire and full of bone,' and all singularly and invariably stamped with the peculiar distinctive marks of their caste—the white blazed face and white legs (generally three); white up to the knee—perhaps the ancestors of the great Eclipse; a chestnut also, with these remarkable marks, and which sometimes break forth in his most distinguished descendants—to wit Sultan, his son Beiram, Harkaway, and a number of winners of our great stakes.'

The Turkish horse is sometimes harnessed to carriages, in the Ottoman empire, where the art of coach-building is still in its infancy—a circumstance which is accounted for by the sedentary character of Turkish habits. The secluded manner of life to which the women of this country are subjected, applies also to the habit of the head of the family himself. As for journeys or promenades, they are in accordance with the jealous manners of the people, who restrict their rambles to parks or secluded retreats in the environs of mansions. In conse-

sequence, carriages are so rarely used that they are comparatively useless; nevertheless, they are to be found as accessories to the best establishments, where they are employed to convey the ladies from the harems to the mosques, to the public baths, and the resorts of pleasure, possessed by the richest Turks in the environs of their residences, or to their country seats in the neighbourhood. For such purposes it is not necessary that the carriages should be of substantial build, similar to those subjected to the wear and tear of London streets. It is, in general, one of these slim vehicles, with its dais covered with drapery, and with decorations, reminding us of the French carriage of the seventeenth century.

The Turks prefer horses for riding; whilst the Arabs prefer mares. According to Bur-ehardt, the price of an Arab horse, in 1815—1816 was from £10 to £120. Some, however, have brought £500; and Burhardt mentions a sheik who paid £100 for a mare, and agreed to give to the seller the first female colt she produced, or to keep the colt and return the mare.

THE CIRCASSIAN HORSE.

On the plains of Circassia, large herds of horses, and flocks of sheep, are reared for purposes of commerce by the Chekernesses. The most valuable breed of the former has a considerable amount of both strength and speed; and is distinguished by having a mark upon it, of a full horse-shoe. Each breed has some peculiar mark; to forge which, or place it on an inferior animal, is punishable with death. Most of the wealthiest families make it their aim to have a peculiar breed of horses for themselves, and, in their own estimation, consider it as excelling that of any other tribe.

THE RUSSIAN HORSE.

The Russian empire comprises all the north part of Asia, and a large portion of Europe. In point of physical extent, it is the largest empire in the world, embracing an area extending from the 18th to the 170th degree of east longitude, and from about the 44th degree of north latitude to the Frozen Ocean. In a country so extensive, it is not to be expected that the horse presents, to our observation, the same features in one place, that it does in
another. Those animals devoted to the purposes of pleasure, as well as those which form the heavy cavalry, are, originally, mostly the descendants of Cossack blood, but greatly improved by having been crossed with Poland, Prussian, Holstein, and English blood. The horses forming the lighter cavalry, are, as they have ever been, mostly Cossacks, which have never been tried to be improved, but which are, nevertheless, extremely hardy, capable of considerable endurance, and well adapted for the duties they have to perform. For a long period it was believed that no horse, except the Arab, was equal to the Cossack for bearing privation, and, at the same time, uniting with this quality so great an amount of speed as it has been found to possess. In 1825, however, the contrary was proved. Two Cossack horses were selected from the best breeds on the Black Sea, the Don, and the Ural, and run against two English ones, which greatly excelled the others both in speed and stamina. On this occasion, the English horses were not of the best breed, and were named Sharper and Mina. The account given of this trial of speed and endurance, shows that it was attended with circumstances the very reverse of such as we should wish to be the accompaniment of similar contests.

"On the 4th of August, 1825, on the challenge of the Cossacks, a race, of the cruel distance of forty-seven miles, out and home, was agreed to. The four horses to start together; and the first in, to take the whole stakes.

"On starting, the Cossacks took the lead at a moderate pace—the English horses following, at the distance of three or four lengths; but, before they had gone half a mile, the stirrup-leather of Sharper broke, and he ran away with his rider, followed by Mina; and they went more than a mile, and up a steep hill, before they could be held in.

"Half the distance was run in an hour and four minutes. Both the English horses were then fresh, and one of the Cossacks. On their return Mina fell lame, and was taken away. The Cossack horse, likewise, began to flag, when the accompanying Russian began to drag him on by the bridle, throwing away the saddle, and putting a mere child on his back. Sharper, likewise, evidently showed the effects of the pace at which he had gone when running away, and was much distressed. The Cossacks then had recourse to foul play, and actually carried on their horse—some dragging him on by a rope, and the bridle at his head; others pulling him forward by the tail; whilst others kept alongside of his quarters to support him; and they relieved each other at this fatiguing work. Sharper did the whole distance in two hours and forty-eight minutes; and the Cossack horse was warped in, eight minutes after him. At starting, the English horse carried three stone more than the Cossacks; and, during the latter half of the race, a more child had ridden the Cossack."

The barbarous cruelty displayed by the Muscovites in this contest, with the unfairness of their whole proceedings, require no comment. They were chagrined at being defeated, and wreaked their ill-feeling upon their animal, because he had not more strength than had been given him by nature.

The last Czar Nicholas was as anxious for the improvement of the Cossack horses, as he was for the general development of the resources of his country; and, with that view, instituted races in different parts of his empire. In southern and western Russia, landed proprietors have recently devoted much of their attention, not only to the horse, but to cattle, endeavouring to bring up their various breeds to a high state of perfection as they can.

Russian noblemen, now, have generally large stables; and the stud of the Russian Countess Orloff Tshemsensky alone, was composed of 1,320 Arabs, English, natives and others. The ground, attached to this stud, comprised nearly 1,100 acres; and the number of grooms, labourers, and others, amounted to 4,000. The better breed of the Tartar horse is sketched by Berenger, in his Treatise on Horsemanship; and although this species would seem to be but of a moderate stature, still they are strong-spirited, bold, and active. They have good feet, but narrow; and their heads are lean and well-shaped. Their fore-hand is long and stiff; but the legs are over-long. With all these imperfections, however, they are good and serviceable horses, endowed with great speed, and not readily succumbing to labour. They are reared in a manner similar to those of the Arabs—being caressed and fondled, and made companions of. When they are six or eight
months old, the Tartars make their children ride upon them; exercise them in small excursions; dress, and, by degrees, reduce them to gentle habits of domestication. After awhile they are made to undergo hunger, thirst, and other privations; but men do not begin to ride them until they have reached their fifth or sixth year. Then they are mounted by their masters, who exact from them the severest duties, and who gradually inure them to support an almost incredible degree of fatigue. They are made to travel two or three days at a time, almost without resting, and pass four or five days without better nourishment than a handful of grass, and without water.

Such are the principal portions of the mode in which the Tartars train their horses, as given by Berenger. The discipline is certainly severe. In the Mazeppa of Lord Byron, we have a beautiful description of a kindred animal to that of the Tartars in the Ukraine:

"The steeds rush on in plunging pride,
But where are they the reins to guide?
A thousand horse, and none to ride!
With flowing tail, and flying mane,
Wide nostrils—never stretch'd by pain—
Mouths bloodless to the bit or rein,
And feet that iron never shod,
And flanks unscarr'd by spur or rod—
A thousand horse, the wild, the free,
Like waves that follow o'er the sea.
On came the troope. * * *
They stop, they start, they snuff the air,
Gallop a moment here and there,
Approach, retire, wheel round and round,
Then plunging back with sudden bound,
They snort, they foam, neigh, swerve aside,
And backward to the forest fly."

This description is applicable to the wild horse, as he is witnessed in his native state, and when we can hardly imagine a scene more sublime than a thousand of his kind, bounding over the vast steppe, with their manes streaming in the wind, until the whole troop is lost in the distance.

**THE SWEDISH HORSE.**

Mr. Lloyd, in his *Field Sports of the North of Europe*, says, that "the Swedish horses are small, though hardy, and capable of considerable exertion; their manes and tails are usually left in a state of nature; they are seldom cleaned; and, when in the stable, even in the most severe weather, are rarely littered down. This treat-ment of their horses arises as much from ignorance as neglect on the part of the peasants. In saying this, however, I am willing to admit that many of them are almost as fond of these animals as if they were their own children. The average price of a good horse, of the description I am now speaking of, may be taken at from five to eight pounds."

The horse of this country is fed almost entirely on bread, composed of equal parts of oatmeal and rye. To this a considerable quantity of salt is added: if setting out on a long journey, a little brandy is given him. Sir A. Brooke, in his *Travels in Sweden*, says—"We were not a little entertained at the curious group formed by the peasants and their steeds breakfasting together; both cordially partaking of a hard rye cake. The horses sometimes belong to three, or even more proprietors; it is then highly amusing to observe the frequent altercation between them, each endeavouring to spare his own horse. Their affection for their horses is so great, that I have seen them shed tears when they have been driven beyond their strength. The expedition, however, with which these little animals proceed, is surprising, when we consider the smallness of their size, which hardly exceeds that of a pony. The roads being universally good through Sweden, they frequently do not relax from a gallop from one post-house to another."

In the Scandinavian forest, it often happens that the wild bear attacks the horse, and, fastening upon him, is borne along by the animal whilst writhing under the wounds inflicted by the claws of the ursine monster. When this is the case, the bear tries to retard the progress of the horse by grasping with one of his paws at the surrounding bushes, which he often, under such circumstances, tears up by the roots. Should he succeed, however, in catching hold of a tree that is firmly embedded in the soil, it is then all over with his victim; for, owing to his immense muscular power, the career of the horse is at once stopped, and he is almost immediately brought to the ground.

It seems rather extraordinary that so clumsy and ill-shaped a looking brute as a bear, should be able to run down a horse; but such, whether owing to the fears of the animal, or to the advantages of ground, is, beyond doubt, of everyday occurrence. Until he has brought his
victor down, however, it is said, the bear sel-
dom makes use of his teeth; but he strikes his victim on the back and sides with his terrible paws, in the same manner as if with a sledge hammer. Sometimes, however, the horse, by flinging out behind, makes his escape; for it is not an uncommon circumstance for a bear to be killed, and found minus an eye or a fang, which the peasants suppose, and with some reason, has probably been caused by the heels of horses.

The wounds which the bear inflicts upon cattle, when he attacks them, are sometimes dreadful to look upon. Mr. Lloyd says that he saw a horse that had been within the clutches of one of these monsters, some few days previously, but from which he had been rescued, owing to an accidental circumstance. In the back and neck of the poor steed, were holes of such a size, that, without exaggeration, he could almost have buried his hand in them; this horse, however, died a few days subsequently.

The sufferings of animals, when attacked by a bear or other wild beast, must often be dreadful. Nearly the whole of the hind-quarters of a cow, or a horse, have been actually devoured, and yet the poor creatures have been found alive.

THE LAPLAND HORSE.

The Laplanders are comprised in two distinct classes, differing entirely from the Swedes in points of person, habits, and language. They consist of a nomadic and a settled class—the one pursuing a wandering life, and the other living in towns. The reindeer is both their solace and their wealth; but they are possessed of a small, eager, and willing species of horse. This little creature is employed in drawing sledges over the snow in winter, and, in summer, is turned into the forests, where he selects certain districts to feed in, and from which he rarely wanders. When these districts no longer supply him with pasture, from the change of the season having set in, he voluntarily returns to his master to be re-yoked to the sledge, or to draw wood for the winter.

To be present in an encampment of Swedish Laps, when preparing to milk their “Reins,” or deer, is one of the most exciting scenes that can be presented to human observation.

The herd is driven within the inclosure, and all outlets guarded. The first thing to be done is to secure the restive reins. Selecting a long thong or cord, a Lap takes a turn of both ends round his left hand, and then gathers what sailors call the “bight” in loose folds held in his right. He now singles out a rein, and throws the bight with unerring aim over the antlers of the victim. Sometimes the latter makes no resistance; but, generally, no sooner does it feel the touch of the thong than it breaks away from the spot, and is only secured by the most strenuous exertions of its capturer. Every minute may be seen an unusually powerful rein furiously dragging a Lap round and round the inclosure, and occasionally fairly overcoming the restraint of the thong, and whirling its antagonist prostrate on the sod. This part of the scene is highly exciting; and one cannot but admire the great muscular strength and the trained skill evinced by all the Laps, women as well as men, who happen to be engaged in it.

The resistance of a rein being overcome, the Lap will take a dexterous hitch of the thong round his muzzle and head, and then fasten him to the trunk of a prostrate tree, which, with many other trees, has been brought within the level inclosure for that special purpose. Even when thus confined, some of the reins plunge in the most violent manner. Men and women then indiscriminately engage both in singling out milk-reins, and in milking them. A wooden bowl is held in the operator’s left hand, and he then slaps the udder of the rein, several times, with the palm of the right hand. After this he moistens the tips of his fingers with his lips, and then rapidly completes the operation. The amount of milk yielded by a single rein is, noticing only bowls which had not previously received contributions, little more than a gill; others give at least double, and a few thrice that quantity; but the fair average is about half a pint.

This milk is as thick as the finest cream from the cow, and is luscious beyond description. It has a pleasing aromatic smell, and, in flavour, reminds us most strongly of coconu

37
from time to time, the bowls are emptied into the kits, &c.

It is impossible to give an adequate idea of the impressive, exhilarating appearance of the whole inclosure. Every soul seems, at this time, fully occupied, for even the little Lap children are practising the throwing of the lasso, and evincing great dexterity, although their strength is insufficient to hold the smallest doe. Many of the young reins attempt to suck the parent doe, but are always beaten away by the Laps. Great quantities of the loose hair on the backs of the reins, at this season fall to the ground at a touch. Of these the women form beds, on which to stretch their reindeer skins, and thus save them from contact with the mud floor of the huts.

THE NORWEGIAN HORSE.

Norway is one of the most mountainous countries in the world, and possesses a larger breed of horses than Sweden. Of their sagacity and affection, the following story may be taken as a proof:—The master of one of these animals had been dining at the neighbouring town, and, when it was time to return, had drunk so much that he could not keep a firm seat in his saddle. The horse seemed to be aware of his master’s condition, for he regulated himself, as well as he could, according to the unsettled motion of his rider; but, happening to make a false step, his master rolled off his back, and hung with one foot entangled in the stirrup. The horse immediately stopped, and, twisting his body in various directions, endeavoured to extricate him, but in vain. The man was severely hurt, and almost helpless; but the shock had brought him to his senses. The horse looked at him as he lay on the ground, and, stooping, laid hold of the brim of his hat, and raised his head a little; but the hat coming off, the man fell again. The animal then laid hold of the collar of his master’s coat, and raised him by it so far from the ground that he was enabled to draw his foot out of the stirrup. After resting awhile, the man regained the saddle, and reached his home. Gratitude towards the preserver of his life, made the man ever afterwards cherish the horse with the utmost kindness, until old age brought the termination of its career.

In Norway, as in Sweden, the horse is sometimes attacked by bears; and if he happen to have a mare or foal with him, he places either behind, and then attacks the others with the utmost fury with his fore-legs. When he adheres to this mode of beating off his enemy, he is generally successful; but if he turns round to strike with his hind legs, the bear immediately runs into him, and he is lost.

In Iceland there is said to be a breed of horses, descended either from the Norwegian or the Scotch.

In Finland, there is also a breed of horses which are said to be beautifully formed, and very swift, although not more than twelve hands high.

THE DANISH HORSE.

The Danish horses are of such an excellent size, and of so strong a make, that they are preferred to almost all others for draught. There are some of them perfectly well shaped; but this is but seldom seen, for, in general, they are found to have a thick neck, heavy shoulders, long and hollow back, and a narrow croup; however, they all move well, and are found excellent both for parade and war. They are of all colours, and often of whimsical ones; some being streaked like the tiger, or mottled like the leopard. A good many years ago there was an importation of some Danish horses in London, which were considered to have good action, and to be very serviceable.

Of the horses belonging to the Feroe Islands, subject to the Danish crown, Be- renger thus speaks:—“They are small of growth, but strong; swift, and sure of foot, going over the roughest places with such certainty, that a man may more surely rely upon them than trust to his own feet. In Suderoe, one of these islands, they have a lighter and swifter breed than in any of the rest. On their backs the inhabitants pursue the sheep, which are wild in this island. The pony carries the man over places that would otherwise be inaccessible to him; follows his rider over others; enters into the full spirit of the chase, and knocks down and holds the prey under his feet until the rider can take possession of it.”

THE FLEMISH OR DUTCH HORSE.

The Flemish horses are a large race, and powerfully formed. They were once fashion-
able in this country as carriage-horses; but they and their descendants are now chiefly employed in agriculture.

THE FRENCH HORSE.

In France, horses of the Bretagne (Brittany) breed are strongly made, and have, generally, black hair, or brown bay; good legs and feet, with a hardy mouth, and a head short and clumsy. The horses of Franche-Comté are said to have the legs of tigers, and the bellies of hinds; but they are short and thick, and of the middle size, being much better adapted for draught than for riding. The horses of Gascony are not unlike those of Spain, but they are not so handsome and active. The best come from Limousin, where they bear a strong resemblance to the Barb, and, like them, are excellent for the chase. They are, however, slow in coming to perfection; should be carefully treated while young; and also should not be backed till they are eight years old. Normandy furnishes the next best, which, though not so good for the chase, are yet better for war. Besides these, there are the horses of Poitou, &c.—all differing from each other in some essential degree; for France, in its vast extent, has various breeds. Great exertions have been made in that country to cope with England in the production of horses. Napoleon I. used every means to procure some of our best blood-animals, and he imported largely from Arabia. But all efforts have hitherto proved unavailing, notwithstanding the French nobility have gone so far as to procure English grooms and jockeys to manage their horses. The beauty, strength, and fleetness of the English horse still bears the bell from all other countries. At Waterloo, the charge of our life-guards proved irresistible; much of which irresistibility must be attributed to the horses they rode, as the French horses are very inferior.

France is said to contain no fewer than 2,500,000 horses; which, of course, includes every description of the species. Of mares there are about 1,300,000, the greater number of which are used for the breeding of mules. Independent of these, somewhere about 40,000 horses are annually imported into this country, either with a view to the improvement of the native breeds, or for the purposes of sale. In reference to the horse employed on the road, Mr. Houël, in a work on the varieties of the horse in France, says—"I have not elsewhere seen such horses at the collar, under the diligence or the post-carriage, or in the farm-cart. They are enduring and energetic beyond description. At the voice of the brutal driver, or at the dreaded sound of his never-ceasing whip, they put forth all their strength, and keep their condition when other horses would die of neglect and hard treatment."

The editor of The Horse says—"Every country that has occupied itself with the amelioration of its breed of horses, has deemed it necessary to have a public register of the names and progeny of those of an acknowledged race. England has had its stud-book nearly half a century, containing a list of all the horses of pure blood that have existed in the country. France, in the year 1837, had her first stud-book, in which are inscribed the names of two hundred and fifteen stallions of pure English blood imported into France, or born there; two hundred and sixty-six Arabs, Barb, Persian, or Turkish horses; two hundred and seventy-four English mares of true blood, and forty-one Eastern mares. This progeny was also traced so far as it was practicable." A work of this kind must necessarily form an epoch in the equestrian annals of any country where it is kept or produced.

THE GERMAN HORSE.

The German horses were originally from Arabian and Barbary stocks; nevertheless they appear to be small and ill-shaped; it is said, also, that they are weak and wispy, with tender hoofs. There are, however, some exceptions, as there are some studs, in which particular attention has been paid, as well to their breed as to their management. The Hungarian horses are excellent for the draught as well as the saddle. Formerly gipsies were the principal horse-dealers in Hungary; but now there are several noble studs scattered over the country, the trade has, in a great measure, passed out of their hands. The Hussars, who use them in war, usually slit their nostrils; which is done, as it is said, to prevent their neighing; but, perhaps, without any real foundation. The cream-coloured breed of horses, used for the state-carriages of the court of England, are of Hanoverian breed.
The imperial establishment for the breeding of horses at Mesohagye's, near Carlsburg, in Austria, is both an excellent and extensive one. It is decidedly the finest in the Austrian dominions for the breeding of horses. The Duke of Ragusa describes it as standing on forty thousand acres of land of the best quality, embracing an area of forty-five miles—surrounded, in its whole extent, by a steep and broad ditch, and a plantation sixty feet wide. Originally it was designed to recruit the cavalry; but now it is devoted to the object of obtaining stallions of a good breed, which are sent to different depots, with a view to keep up the necessary supply for the various provinces. To produce these, one thousand brood mares and forty-eight stallions are kept; two hundred additional mares, and six hundred oxen, are maintained to cultivate the ground. "The plain," says the duke, "is divided into four equal parts, and each of these subdivided into portions, resembling so many farms. At the age of four years, the young horses are all collected in the centre of the establishment. A selection is first made of the best animals, to supply the deficiencies in the establishment, in order always to keep it on the same footing. A second selection is then made from the other horses: none of these, however, are sent away until they are five years old; but the horses that are not of sufficient value to be selected, are sold by auction, or sent to the army to keep up the cavalry, as circumstances may require.

"The imperial treasury advances to the establishment, every year, eighteen thousand florins, and is reimbursed by the sale of one hundred and fifty stallions, which are sent to the provinces every year, at the price of one thousand florins each; and by the value of the horses supplied to the cavalry. The value of a florin is about 2s. 1d. English money. All the other expenses incident to the maintenance and tear and wear of the establishment, are defrayed by what it, in itself, produces. This is, therefore, an immense estate—a farm on a colossal scale—with a stud in proportion, managed on account of the sovereign, and which produces a considerable revenue, independently of the principal object which is attained—the propagation and the multiplication of the best breeds of horses. He can always supply the wants of his army at a price almost incredibly small. For a horse of the light cavalry he pays only one hundred and ten florins; for the dragons, one hundred and twenty; for the cuirassiers, one hundred and forty; for the train, one hundred and sixty; and for the artillery, one hundred and eighty. It is a great element of power to possess at home such an immense resource against a time of war, at an expense so far below that which the powers of the west and south of Europe are compelled to incur."

It is from the originally warlike character of the Germans that their country takes its name—Germany being derived from the Teutonic German, a warring man.

In Prussia the government has established some extensive studs in different parts of the kingdom, and many noblemen of this country are in the possession of excellent establishments of their own. About the mouth of the Vistula there exists a large breed of horses well-adapted for agricultural purposes; but in the royal studs, attention has more especially been paid to the improvement of the cavalry horse, which now takes very high rank.

**The Italian Horse.**

Of this animal little need now be said. Like everything else in this naturally fine country, the horse "has fallen from his high estate," and is now all but worthless. The races, as they were wont to be run in the days of Mrs. Piozzi, are thus described by the pen of that lively lady:—"The street is covered with sawdust, and made fast at both ends. Near the starting-post are elegant booths, lined with red velvet, for the court and first nobility. At the other end a piece of tapestry is hung, to prevent the creatures from dashing their brains out when they reach the goal. Thousands and tens of thousands of people, on foot, fill the course, so that it is a great wonder, to me, still that numbers are not killed. The prizes are exhibited to view in quite the old classical style—a piece of crimson damask for the winner; a small silver basin and ewer for the second; and so on, leaving no performer unrewarded."

"At last come out the horses without
riders, but with a narrow leathern strap hung across their bodies, which has a lump of ivory fixed to the end of it, all set full of sharp spikes like a hedgehog; and this goads them along while galloping, worse than any spur could do; because the faster they run, the more this odd machine keeps jumping up and down, and pricking their sides ridiculously enough; and it makes one laugh to see that some of them are so tickled by it, as not to run at all, but set about plunging in order to rid themselves of the inconvenience, instead of driving forward to divert the mob, who leap and caper, and shout with delight, and lash the laggards along with great indignation indeed, and with the most comical gestures."

Races of a similar kind take place at Rome.

THE SPANISH HORSE.

Spain was early celebrated for a breed of fine horses, which took its rise in the Moorish Barb, when that peninsula was subject to the Moors. When Rome was at its highest splendour, the horses of Calpe—the modern Gibraltar—were in high repute. This part of Spain being situated at the south-western extremity of the Peninsula, opposite the Barbary coast, horses were readily imported from north-western Africa; and hence the origin of the genettes. The Spanish horses are well made and handsome, as well as very active and nimble; they have fine eyes, handsome legs and heads, and are docile, and easily managed.

For many centuries they took rank after the Arabian and Barb; but they could not be considered as being other than Barbs themselves, having been only transplanted to European soil, where, although they might have become slightly altered in appearance by the change, they suffered no material injury. "I have seen many Spanish horses," says Solleysel, "and they are all extremely beautiful. They are the most proper of all to be drawn by a curious pencil, or to be mounted by a king, when he unbends to show himself in his majestic glory to the people."

The common breeds of the Spanish horses, however, are not to be confounded with the warrior sorts—they having nothing extraordinary in them. It is in Andalusia, Estremadura, and Granada, that the highest races are to be found. Berenger, who was an excellent judge, thus describes them:—"The neck is long and arched, perhaps somewhat thick, but clothed with a full and flowing mane; the head may be a little too coarse; the ears long, but well-placed; the eyes large, bold, and full of fire; their carriage lofty, proud, and noble; the breast large; the shoulders sometimes thick; the belly frequently too full and swelling; and the loins a little too low; but the ribs round, and the croup round and full; with the legs well formed, and clear of hair; and the sinews at a distance from the bone; active and ready in their paces; of quick apprehension; a memory singularly faithful; obedient to the utmost proof; docile and affectionate to man, yet full of spirit and courage."

The food of the modern Spanish horse consists principally of chopped straw, with a little barley. During the Peninsular war, when the French and English cavalry horses were placed on this fare in Spain, they at first became very much weakened, and many of them died; but, when they grew a little accustomed to it, they regained their strength, and, consequently, their spirit and courage.

THE PORTUGUESE HORSE.

The Lusitanian or Portuguese horse was, at one time, so highly celebrated for its speed, that the Roman historian, Justin, compares it to the velocity of the wind. Berenger, however, who lived before the glory of the Spanish horse had entirely faded away, says that "the Portuguese horses are in no repute, and differ as much from their neighbours, the Spaniards, as crabs from apples, as aloe from grapes." After the annexation of Portugal to Spain, the latter country was preferred for establishing studs; and the former directed its attention rather to the rearing of cattle for the shambles and the plough, and mules and asses for draught. Here, then, the horse became rather the associate of pomp and pleasure; and such as were wanted, were mostly imported from Spain. The horse is now, however, receiving greater attention than, for a long period, has been devoted to it.

THE IRISH HORSE.

In some of the rich grazing counties of Ireland, such as Meath and Roscommon, a large long blood-horse is reared, of considerable
value; but he seldom has the elegance of the English animal. He is larger headed, more leggy, ragged-hipped, angular, yet with great power in the quarters, much depth beneath the knee, stout and hardy, full of fire and courage, and among the best leapers in the world. He is not generally, however, so tall as the English horse, being stunted in his growth; for the poverty and custom of the country impose upon him much hard work, at a time when he is unfit for labour of any kind. For this reason, too, the Irish horse is deficient in speed. There is, however, another explanation of this; and that is, that the thorough-bred Irish horse is not equal to the thorough-bred English. Comparatively speaking, he is a weedy, leggy, worthless animal, and very little of him enters into the composition of the hunter or the hackney.

For leaping, the Irish horse has long been considered unrivalled. It is not, however, the leaping of the English horse, striding, as it were, over a low fence, and stretched at his full length over a higher one. It is rather the proper jump of the deer—beautiful to look at, and, both in height and extent, unequalled by the English horse. Much of this difference of leaping in the two countries, no doubt, depends on the training, and on the nature of the fences in Ireland, where there are so many inclosures with stone walls.

There are very few horses in the agricultural districts of Ireland, exclusively devoted todraught. The minute division of the farms renders it impossible for them to be kept. The occupier even of a tolerably sized Irish farm, wants a horse that shall carry him to market, and draw his small car, and perform every kind of drudgery—in short, a horse of all work; therefore the thorough draught-horse, whether Leicestershire or Suffolk, is rarely found in Ireland.

If we look to the general commerce of Ireland, there are few stage-waggons, or drays with immense cattle belonging to them. In the north, some stout horses are employed in the carriage of linen; but the majority of the garrons used in agriculture or commercial pursuits, are miserable and half-starved animals.

There is a native breed in Ulster, hardy, and sure-footed, but with little pretension to either beauty or speed.

---

THE HORSE IN HIS NATIVE STATE.

We have purposely reserved, till now, our description of the horse in his native state, as seen in the boundless Llanos, or savannas and prairies of South and North America, where he is entirely free, and where he is seen to the greatest advantage amidst his native pastures. To form anything like a correct idea of this noble animal in his native simplicity, we must not look for him in the pastures or the stables to which he has been consigned by man; but in those wild and extensive plains where he has been originally produced, whether in the Old or the New World, and where he ranges at will and riot in the unrestrained license of a rich, a varied, and a luxuriant vegetation. In this state of happy independence he disdains the assistance of man, which only tends to servitude. In the interminable Llano, or prairie, where he wanders at liberty, he seems no way incommoded by the inconveniences to which he is subjected in Europe. The verdure of the broad expanse of grass supplies his wants; and the climate that never knows a winter, is, perhaps, more congenial to his constitution than any other, as he naturally seems to be fond of heat. His enemies of the forest are but few, for none but the larger kinds will venture to attack him: and any one of these he is, singly, mostly able to overcome; while, at the same time, he is content to find safety in society; for the wild horses of those countries always herd together. A gentleman describing what he himself had witnessed with a friend whilst travelling in South America, thus notices the horse in his native or wild state:

"About half-past ten we discerned a creature in motion at an immense distance, and instantly started in pursuit. Fifteen minutes' riding brought us near enough to discern, by its fleetness, that it could not be a buffalo; yet it was too large for an antelope, or a deer. On we went, and soon distinguished the erect head, the flowing mane, and the beautiful proportions of the wild horse of the prairie. He saw us, and sped away with arrowy swiftness, till he gained a distant eminence, when he turned to gaze at us, and suffered us to approach within four hundred yards, and then bounded away again in another direction, with a graceful velocity delightful to behold. We paused, for
to pursue him with a view to capture, was out of the question. When he discovered we were not following him, he also paused, and now seemed to be inspired with curiosity equal to our own; for, after making a slight turn, he came nearer until we could distinguish the inquiring expression of his clear, bright eye, and the quiet curl of his inflated nostrils. We had no hope of catching, and did not wish to kill him, but our curiosity led us to approach him slowly. We had not advanced far before he moved away, and, circling round, approached on the other side. He was a beautiful animal—a sorrel, with jet black mane and tail. As he moved we could see the muscles quiver in his glossy limbs; and, when half playfully, and half in fright, he tossed his flowing mane in the air, and flourished his long silky tail, our admiration knew no bounds, and we longed—hopelessly, vexatiously longed—to possess him. We might have shot him where we stood; but had we been starving, we could scarcely have done it.

He was free, and we loved him for the very possession of that liberty we longed to take from him; but we would not kill him. We fired a rifle over his head; he heard the shot, and the whiz of the ball, and away he went, disappearing in the next hollow—showing himself again as he crossed the distant ridges—still seeming smaller, until he faded away a speck on the far horizon's edge."

The wild horses which exist in the Llanos of South America, are descendants of those introduced by the Spaniards. In the province of Cumana, there are great numbers in the forest, wandering about in companies, generally to the number of five or six hundred. They occupy the great savannas, where it is difficult even to disturb, far less to catch them. In the dry season, they are sometimes obliged to go eight, ten, and even more miles in search of water; and when this is the case they set out in regular ranks, four abreast. Five or six scouts precede the troop by about fifty paces. If they perceive an enemy they neigh, and the troop stops; if they evade him, they continue their march; but if any one dares to march across their squadron, they turn on him and crush him under their feet. No foe is capable of withstanding their attack. They have a regular chief, who marches between the scouts and the squadron—a kind of adjutant, whose duty consists in hindering any individual from quitting the ranks. If any one attempts to straggle, either from hunger or fatigue, he is bitten till he resumes his place. When wild horses are feeding, should any stragglers be threatened with danger by an enemy, a particular signal, which they all understand, is given, when they close into a dense mass, and trample the assailant to death. When they themselves resolve upon making an attack, their leader shows the example; and if he considers a retreat necessary, he gives the signal, and it is instantly obeyed.

The wild horses of Tartary, although easily domesticated, materially differ in character from those on the plains of South America. They will not suffer a stranger to join them. If a domesticated horse come in their way, unprotected by his master, they attack him with their teeth and their heels, and speedily destroy him. They readily submit, however, to the dominion of man, and become perfectly docile and faithful.

Among the Tartars, the flesh of the horse is a frequent article of food; and although they do not, like the Indians of the Pampas, eat it raw, their mode of cookery would not be very inviting to the European epicure. They cut the muscular parts into slices, and place them under their saddles; and after they have galloped thirty or forty miles, the meat becomes tender and sodden, and fit for their table; and, at all their feasts, the first and last, and most favourite dish, is a horse's head.

When water was not at hand, the Scythians used to draw blood from their horses, and drink it; and the Dukes of Muscovy, for nearly two hundred and sixty years, presented Tartar ambassadors with the milk of mares. If any of this milk fell upon the mane of the horse, the Duke, by custom, was bound to lick it off.

Troops of wild horses are occasionally met with in the central parts of Africa, the deserts of Arabia, and in a few other parts of the world; but nowhere do they equal the domesticated horse in form, strength, or even speed.

The Quagga, in the Zoological Society's valuable collection in Regent's-park, London, belongs to the same family of animals as the horse (equidae). This specimen is brown;
head, neck, and withers, or front of body, blackish streaked; lower part of body, legs, and tail, white. The hoofs are flatish beneath. It is a native of the Cape of Good Hope, where it lives on the open plains. The Quagga is said to derive its name from the sound of its voice. Thus we read in Pringle:—

"The timorous quagga's wild whistling neigh Is heard by the brak fountain far away."

Methuen, in his Life in the Wilderness, informs us, that when the supply of antelope meat of his party was exhausted, they occasionally had recourse to a steak from the quagga, and found it very sweet and good, though it looked coarse, and was marbled with yellow fat. He advises travellers in the wilderness, who have an antipathy to anything like horse-flesh, to try to get rid of their dislike as fast as possible; and assures us that the Griquas, a nation who dwell in South Africa, prefer the meat of the quagga to almost any other; while his cook Apollos, who was with the British troops in their expedition to Natal, and was blockaded with them in the trenches by the Boors (when they were compelled to feed on horse-flesh), was particularly fond of quagga steaks, and regarded them as the most savoury food he could obtain.

THE WILD HORSE OF SOUTH AMERICA.

All travellers, who have crossed the plains extending from the shores of La Plata to Patagonia, have spoken of numerous herds of wild horses. Some affirm that they have seen ten thousand in one troop, all apparently under the command of a leader, the strongest and boldest of the herd, whom they implicitly obey. A secret instinct teaches them that their safety consists in their union, and in a principle of subordination. The lion, the tiger, and the leopard are their principal foes, which, as we have said, they trample to death, being led on by their leader, which is the first to face the danger. Should the prudence of their leader suggest the necessity of a retreat, the whole troop follow in his wake.

In the thinly inhabited parts of South America it is dangerous to fall in with any of these troops, as when they see a horse mounted, they approach as near as they dare, and call upon the mounted horse with much eagerness.

On such an occasion, if the rider be not on the alert, and have not considerable strength of arm, and sharpness of spur, his beast will divest himself of his burden, take to his heels, and be gone for ever.

Captain Head gives the following account of a meeting with a troop of wild horses, where the country is more thickly inhabited. Some poor captured animals are supposed to be forced along by their riders, at their very utmost speed:—"As they are thus galloping along, urged by the spur, it is interesting to see the groups of wild horses one passes. The mares, which are never ridden in South America, seem not to understand what makes the poor horse carry his head so low, and look so weary. The little innocent colts come running to meet him, and then start away frightened; while old horses, whose white marks, on the flanks and backs, betray their acquaintance with the spur and saddle, walk slowly away for some distance; then, breaking into a trot as they seek their safety, snort and look behind them, first with one eye, and then with the other, turning their nose from right to left, and carrying their long tail high in the air."

The same pleasing writer describes the system of horse-management among the rude inhabitants of the plains of South America. They have no stables, no fenced pastures. One horse is usually kept tied at the door of the hut, fed scantily at night on maize; or, at other times, several may be enclosed in the corral, which is a circular space surrounded by rough posts driven firmly into the ground. The mares are never ridden or attempted to be tamed, but wander, with their foals, wherever they please.

When the Gaucho, the native inhabitant of the plains, wants horses for himself or for the supply of the traveller, he either goes with his lasso to the corral, and seizes those, possibly, who, on the preceding day, had for the first time been backed, or he scampers across the plain, and presently returns with an unwilling, struggling, or subdued captive.

When the services of the animals have been exacted, he either takes them to the corral, and feeds them with a small quantity of maize, if he thinks he shall presently need them again, or he, once more, turns them loose on the plains.
Travellers give some amusing accounts of the manner in which all this is effected. Miers thus describes the lasso, simple in its construction, but all-powerful in the hands of the Gaacho.

"The lasso is a missile weapon used by every native of the United Provinces and Chili. It is a very strong plaited thong of equal thickness, half an inch in diameter, and forty feet long, made of many strips of green hide, plaited like a whipthong, and rendered supple by grease. It has, at one end, an iron ring above an inch and a-half in diameter, through which the thong is passed, and this forms a running noose. The Gaacho, or native Peon, is generally mounted on horse-back when he uses the lasso. One end of the thong is affixed to his saddle girth: the remainder he coils carefully in his left hand, leaving about twelve feet belonging to the noose-end, in a coil, and a half of which he holds in his right hand. He then swings this long noose horizontally round his head, the weight of the iron ring, at the end of the noose, assisting in giving to it, by a continued circular motion, a sufficient force to project it the whole length of the line."

When the Gauchos wish to have a grand breaking-in, they drive a whole herd of wild horses into the corral. "The corral was quite full of horses, most of which were young ones about two or three years old. The capitar (chief Gaacho), mounted on a strong steady horse, rode into the corral, and threw his lasso over the neck of a young horse, and dragged him to the gate. For some time the colt was very unwilling to leave his comrades; but the moment he was forced out of the corral, his first idea was to gallop away; however, a timely jerk of the lasso checked him in the most effectual way. The peons now ran after him on foot, and threw a lasso over his fore-legs, just above the fetlock; and twitching it, they pulled his legs from under him so suddenly, that I really thought the fall he got had killed him. In an instant a Gaacho was seated on his head, and, with his long knife, and in a few seconds, cut off the whole of the horse's mane, while another cut the hair from the end of his tail. This, they told me, was a mark that the horse had been once mounted. They then put a piece of hide into his mouth, to serve for a bit, and a strong hide halter on his head. The Gaacho who was to mount, arranged his spurs, which were unusually long and sharp; and, while two men held the horse by his ears, he put on the saddle, which he girded extremely tight. He then caught hold of the horse's ear, and, in an instant, vaulted into the saddle; upon which the man who held the animal by the halter, threw the end to the rider, and, from that moment, no one seemed to take any further notice of him.

"The horse, instantly, began to jump in a manner which made it very difficult for the rider to keep his seat, and quite different from the kick or plunge of an English horse: however, the Gaacho's spurs soon set him going, and off he galloped, doing everything in his power to throw his rider.

"Another horse was immediately brought from the corral; and so quick was the operation, that twelve Gauchos were mounted in a space which, I think, hardly exceeded an hour. It was wonderful to see the different manner in which different horses behaved. Some would actually scream while the Gauchos were girding the saddle upon their backs; some would instantly lie down and roll upon it; while some would stand without being held—their legs stiff, and in unnatural positions; their necks half bent towards their tails, and looking vicious and obstinate; and I could not help thinking that I would not have mounted one of those for any reward that could be offered me, for they were invariably the most difficult to subdue.

"It was now curious to look around and see the Gauchos on the horizon, in different directions, trying to bring their horses back to the corral, which is the most difficult part of their work; for the poor creatures had been so scared there, that they were unwilling to return to the place. It was amusing to see the antics of the horses—they were jumping and dancing in different ways, while the right arm of the Gauchos was seen flogging them. At last they brought the horses back, apparently subdued, and broken in. The saddles and bridles were taken off, and the young horses trotted off towards the corral, neighing to one another."

The manufacture of the Gaacho's boots is somewhat singular. "They are formed of the ham and part of the leg-skin of a colt taken
THE HORSE, AND [WILD HORSE.]

recked from the mother, which is said to be sacrificed for the sole purpose, just at the time of bearing when the hair has not begun to grow. At this stage the skin strips off easily, and is very white and beautiful in texture and appearance. The ham forms the calf of the boot; the hock easily adapts itself to the heel; and the leg above the fetlock constitutes the foot; the whole making a neat and elegant half-boot, with an aperture sufficient for the great toe to project through.

When the Gaucho wishes to take a wild horse, he mounts one that has been used to the sport, and gallops over the plain. As soon as he comes sufficiently near his prey, "the lasso is thrown round the two hind-legs; and as the Gaucho rides a little on one side, the jerk pulls the entangled horse's feet laterally, so as to throw him on his side, without endangering his knees or his face. Before the horse can recover the shock, the rider dismounts, and snatching his poncho or cloak from his shoulders, wraps it round the prostrate animal's head. He then forces into his mouth one of the powerful bridles of the country, straps a saddle on his back, and bestriding him, removes the poncho; upon which the astonished horse springs on his legs, and endeavours, by a thousand vain efforts, to disencumber himself of his new master, who sits quite composedly on his back, and, by a discipline which never fails, reduces the animal to such complete obedience, that he is soon trained to lend his whole speed and strength to the capture of his companions."

These animals possess much of the form of the Spanish horse, from which they sprung. They are tamed, as has been seen, with far less difficulty than could be thought possible; and, although theirs is the obedience of fear, and enforced at first by the whip and spur, there are no horses that so soon and so perfectly exert their sagacity and their power in the service of man. They are possessed of no extraordinary speed; but they are capable of enduring immense fatigue, and are frequently ridden fifty or sixty miles without drawing bit. Indeed, it is known that they have been urged on by the cruel spur of the Gaucho, more than a hundred miles, and at the rate of twelve miles in the hour.

Like the Arab horses, they know no intermediate pace between the walk and the gallop. Although, at the end of a day so hard, their sides are horribly mangled, and they themselves so completely exhausted, there is this consolation for them—that they are immediately turned loose on the plains, and it will be their own fault if they are speedily caught again. The mare is occasionally killed for food, and, especially, on occasions of unusual festivity. General San Martin, during the war for independence, gave a feast to the Indian allies attached to his army; and the flesh of mares, with the blood mixed with gin, formed the whole of the entertainment.

On such dry and sultry plains the supply of water is often scanty. When this is the case, a species of madness seizes on the horses, and their generous and docile qualities are no longer recognised. They rush violently into every pond and lake, savagely mangling and trampling upon one another; and the carcases of many thousands of them, destroyed by their fellows, have occasionally been seen in and around a considerable pool. This is one of the means by which the too rapid increase of this quadruped is, by an ordinance of Nature, prevented. It is observed by Humboldt, that during the periodical risings of the large rivers, vast numbers of wild horses are drowned. This is especially the case when the Apure is swollen, and when these animals attempt to reach the rising grounds of the Llanos.

The bolas is another instrument which is occasionally brought into requisition by the Gauchos for the catching of wild horses. It consists of two balls, of two kinds, attached to thongs. The first is composed of three round stones, about the size of a man's fist, covered with strong leather, and attached to a common centre by tough leathern cords, three feet long. The smallest of the three is taken in the hand; and, after whirling the others violently round the head, the whole are thrown to the distance of about one hundred feet, when they so maim and entwine themselves round the limbs of any living creature, that it is impossible to escape from them. The other kind is a single ball of the same size, except when it is made of iron or copper, it being then smaller. It is also covered with leather, and has a leathern thong attached, by which it is whirled round, and, at the hard gallop,
projected with immense force to the distance of five hundred feet. The launching of this weapon amidst a tribe of wild horses, is thus described by Robertson, in his History of Paraguay:

"The herd consisted of about two thousand horses, neighing and snorting, with ears erect and flowing tails, their manes outspread to the wind—affrighted the moment they were conscious of pursuit. The Gauchos set up their usual cry; the dogs were left in the distance; and it was not till we had followed the flock at full speed, and without a check, for five miles, that the two headmost peons launched their bolas at the horse which each had respectively singled out of the herd. Down to the ground, with frightful somersaults, came two gallant colts. The herd continued its headlong flight, leaving behind their two prostrate companions. Upon these the whole band of Gauchos now ran in; lassos were applied to tie their legs; one man held down the head of each horse, and another the hind quarters; while with singular dexterity, two other Gauchos put the saddles and bridles on their fallen, trembling, and nearly frantic victims. This done, the two men who had brought down the colts, bestrode them as they still lay on the ground. In a moment the lassos which bound their legs were loosened, and, at the same time, a shout from the field so frightened the colts, that up they started on all fours, but, to their astonishment, each with a rider on his back, riveted, as it were, to the saddle, and controlling them by means of a never-before-dreamed-of bit in his mouth. The animals made a simultaneous and most surprising vault; they reared, plunged, and kicked; now they started off at full gallop, and anon stopped short in their career, with their heads between their legs, endeavouring to throw their riders. Immovable sat the two Indians; they smiled at the unavailing efforts of the turbulent and outrageous animals to unseat them; and, in less than an hour from the time of their mounting, it was very evident who were to be the masters. The horses did their very most; the Indians never lost either the security or the grace of their seats; till, after two hours of the most violent efforts to rid themselves of their burden, the horses were so exhausted, that, drenched in sweat, with gored and palpitating sides, and hanging down their heads, they stood for five minutes together, panting and confounded; but they made not a single effort to move. Then came the Gaicho's turn to exercise his more positive authority. Hitherto he had been entirely upon the defensive. His object was simply to keep his seat, and tire out his horse. He now wanted to move it in a given direction: wayward, zigzag, often interrupted was his course at first; still the Gauchos made for a given point, and they advanced towards it; till, at the end of about three hours, the now mastered animals moved in nearly a direct line."

In 1537, horses were first landed at Buenos Ayres, in South America; and between forty and fifty years afterwards, they were found wild at the Straits of Magellan. From that time to this, they have continued to multiply and extend the range of their existence. North, south; east, and west, the horse abounds in the American hemisphere. At Terra-del-Fuego, almost every man, woman, and child, have their horses; even the Indians have them: and, it is not a little remarkable, that the countless troops that now skirt the Llanos of the South, and the prairies of the North, should all have sprung from the Iberian stock first taken into Mexico by Cortes, and into Peru by Pizarro.

We have already alluded to the fact of the horse having been, at some remote period, a denizen of the American continent. Professor Owen thinks that they existed there even before the creation of man. In his work on British Fossil Mammals, he says—"The species of equus which existed during the Miocene periods of geology, in both North and South America, appears to have been blotted out of the Fauna of those continents before the existence of man. The aborigines, whom the Spanish conquistadores found in possession of Peru and Mexico, had no tradition or hieroglyphic indicative of such a quadruped; and the horses, the invaders imported from Europe, were viewed with astonishment and alarm. The researches of Mr. Darwin and Mr. Lund, have indisputably proved that the genus equus was represented during the Pliocene period, by a species (equus curvidens) which is shown to be distinct from the European fossils, and also from the existing species. Fossil remains of the horse have been found also in North 47
America. The geographical range of the genus equus was, therefore, more extensive at the Pliocene period, than that of the rhinoceros, of which both the fossil and the existing species are confined to the Old World of the geographers. The horse, in its ancient distribution over both hemispheres of the globe, resembles the mastodon, and appears to have become extinct in North America at the same time with the mastodon giganteus, and in South America, with the mastodon of the Andes, and the megatherium. Well may Mr. Darwin say—"It is a marvellous event in the history of animals, that a native kind should have disappeared, to be succeeded, in after ages, by the countless herds introduced with the Spanish conquerors."

THE NORTH AMERICAN HORSE.

Traversing the isthmus of Darien, and entering North America, we find herds of wild horses, the offspring of those which formerly escaped from the Spanish possessions in Mexico—even abounding on the extensive prairies that lie to the west of the Mississippi. They were once numerous on the Kootanies, Lands, near the northern sources of the Columbia. The young stallions live in separate herds, being driven away by the old ones, and are easily ensnared by using domestic mares as a decoy. The natives are acquainted with the Spanish-American method of taking them with the lasso. Major Long mentions that "horses are an object of a particular hunt to the Osages. For the purpose of obtaining these animals—which, in their wild state, preserve all their fleetness—they go in a large party to the country of the Red Canadian river, where they are to be found in considerable numbers. When they discover a troop, they distribute themselves into three parties, two of which take their stations at different and proper distances on the route, which, by previous experience, they know the horses will most probably take when endeavouring to escape. This arrangement being completed, the first party commences the pursuit in the direction of their colleagues, at whose position they at length arrive. The second party then continues the chase with fresh horses, and pursues the fugitives to the third party, which generally succeeds in so far running them down, as to noose and capture a considerable number of them."

The domestic horse is an object of great value to the nomadic tribes of Indians that frequent the extensive plains of the Missouri, &c.; for they are not only useful in transporting their tents and families from place to place, but one of the highest objects of the ambition of a young Indian, is to possess a good horse for the chase of the buffalo—an exercise of which he is passionately fond. To steal the horse of an adverse tribe is considered to be nearly as heroic an exploit as killing an enemy on the field of battle; and the distance to which they occasionally travel, and the privations they undergo in their horse-marauding excursions, are almost incredible. An Indian who owns a horse, scarcely ever ventures to sleep after night-fall; but sits at the door of his tent, with the halter in one hand, and his gun in the other; the animal's fore-legs being, at the same time, tied together with thongs of leather. Notwithstanding all this care, however, it happens very often that the hunter, suffering himself to be overpowered by sleep for a few moments, awakes from the noise made by the thief galloping off with his animal.

In Great Britain, opportunities by which the swimming powers of the horse might be tested, rarely occur. Mr. Darwin says, that when he was in South America, "I crossed the Lucia near its mouth, and was surprised to observe how easily our horses, although not used to swim, passed over a width of, at least, six hundred yards. On mentioning this at Monte Video, I was told that a vessel containing some mountebanks and their horses, being wrecked in the Plata, one horse swam seven miles to the shore. In the course of the day, I was amused by the dexterity with which a Gaucho forced native horses to swim a river. He stripped off his clothes, and jumping on the back of the animal, rode into the water till it was out of its depth; then slipping off over the crupper, he caught hold of the tail; and as often as the horse turned, the man frightened it back by splashing water in its face. As soon as the horse touched the bottom on the other side, the man pulled himself on, and was firmly seated, bridle in hand, before the horse gained the bank. A naked man on a naked horse is a fine spectacle. I had no idea how well the
two animals suited each other. The tail is a very useful appendage. I have passed a river in a boat, with four people in it, which was ferried across in the same way as the Gaucho. If a man and horse have to cross a broad river, the best plan is for the man to catch hold of the pommel or mane, and help himself with the other arm."

In Pennsylvania, a horse called the Conestoga, long in the legs, and light in the carcass, is found. Its height is about seventeen hands, and it is used principally as a carriage-horse. This animal is pretty general in the middle states. In Kentucky and Virginia, the English horse, with a fair quantity of blood, is found. Also in the Southern states, where purity has had greater attention. Shark, the best English horse of his day, was the sire of the best stock in Virginia; and Tally-ho gave his offspring to the Jerseys.

THE CANADIAN HORSE.

Winter travelling in Canada is sometimes very expeditious; and it is surprising with what speed a good Canadian horse will go, when drawing a cabriolet over the ice. Instances have occurred of their travelling ninety miles, in one of these vehicles, in twelve hours; but, when this happens, the roads must be very smooth and hard.

The Canadian horse is a remarkably hardy animal; his best pace is a trot; and although he is accustomed to much bad usage and hard work, he is the most willing creature in the world—as the jockeys term it—for he never refuses the draught. In the coldest weather horses come into Quebec from the country, and are left standing in the open air, without any covering, for hours together, while their owners are transacting their business, or drinking; yet they seem not to be any the worse for it. In the winter, like all other quadrupeds of that country, they acquire an increased quantity of fur to protect them from the cold; and the curry-comb is never used. When they have been heated by fast driving on a cold day, they appear to have a sort of icicle at every hair; and icicles, two or three inches in length, often hang at their noses.

In the winter season, travelling on the ice is at all times dangerous; and it is very common for sleigh, horses, and men, to fall through the ice where the water is some hundred feet deep: luckily, however, the weak places are of no great extent, and the traveller extricates himself from the sleigh as quickly as possible, when he lays hold of the ice, which is generally strong enough to support him, though it will not bear the weight of the horses. The pulling of these out is done in a manner perfectly unique, the horses being often nearly strangled to save them from suffocation.

When the horses fall through—for there are generally two in these sleighs—their struggles only tend to injure and sink each other; but as they have always round their necks a rope with a running noose, the moment the ice breaks, the driver and passengers jump out, and catching hold of the rope, pull it with all their force. This, in a very few minutes, stops the breath of the horses; and no sooner does this happen, than they rise in the water, float on one side, and are drawn out on strong ice, when the noose of the rope being loosened, respiration returns. In a short time, the horses are on their feet, and as mud alive as ever. This operation has been known to be performed two or three times a-day on the same horses. The Canadians state, that horses which are often on the lakes, become so accustomed to being hanged, that they think nothing at all of it. But, though the case is very common, the attempt does not always succeed; for it sometimes happens that both sleigh and horses go to the bottom, if not extricated in time.

Another remarkable fact respecting the Canadian horses, is said to be a great fondness for fish. To what extent they carry this singular appetite we have never heard described. The kind of fish is said to be a species of cod; and the manner of catching them is by cutting holes in the ice, and putting down either nets or lines. Over this hole a temporary house is built, large enough to contain half-a-dozen fishermen, and a stove to keep them warm. Such as cannot afford deals to build a house, substitute large pieces of ice, with which they form a kind of defence against the weather, and literally pursue their piscatory sport in an ice-house.

A correspondent of the Penny Magazine, sent to that periodical the following instance of sagacity in the North American horse:

"A short distance below Fort Erie, and about
a mile from where the river Niagara escapes over a barrier of rock from the depths of Lake Erie, a ferry has long been established across that broad, and there exceedingly rapid, river; the distance from shore to shore being a little over one-third of a mile. On the Canada side of the river is the small village of Waterloo; and opposite thereto, on the United States' side, is the large river of Black Rock, distant from the young and flourishing city of Buffalo two miles. In completing the Erie canal, a pier or dam was erected—up and down the river, and opposite to Black Rock, at no great distance from the shore, for the purpose of raising the waters of the Niagara to such a height that they might be made to supply an adjoining section of the Erie canal. This pier was a great obstruction to the ferry-boats; for, previous to its erection, passengers embarked from terra firma on one side of the river, and were landed, without any difficulty, on the other; but, after this dam was constructed, it became necessary to employ two sets of boats—one to navigate the river, and the other the basin; so that all passengers, as well as goods or luggage, had to be landed on this narrow wall, and reshipped. Shortly after the erection of the pier-dam, a boat, propelled by horses, was established between this pier and the Canada shore. The horses moved upon a circular platform, which, consequently, was put in motion; to which other machinery was connected, that acted upon paddle-wheels attached to the sides of the boat. The boat belonged to persons connected with the ferry on the American side of the river; but, owing to the barrier formed by the pier, the horses employed on the boat were stabled at night in the village of Waterloo. The two horses—for that boat had but two—worked admirably, considering the very few lessons they had had previous to their introduction upon the main river. One of the horses employed on the new ferry-boat, had once been a dapple-grey; but, at the period I am speaking of, he had become white. He was still hale and hearty, for he had a kind and indulgent master.

"The first evening after the horses had been a short time in the stable to which they were strangers, they were brought out for the purpose of being watered at the river—the common custom of this place. The attendant was mounted on the bay horse; the white one was known to be so gentle and docile that he was allowed to drink where he pleased. I happened to be standing close by, in company with my friend W——, the ferry contractor of the Canada side, and thus had an opportunity of witnessing the whole proceedings of "Old Grizzle," the name that the white horse still went by. The moment he got round the corner of the building, so as to have a view of his home on the opposite side, he stopped and gazed intently. He then advanced to the brink of the river, when he again stopped, and looked earnestly across for a short time; then waded into the water until it had reached his chest—drank a little, lifted his head, and, with his lips closed, and his eyes fixed upon some object upon the furthest shore, remained for a short time perfectly motionless. Apparently having made up his mind to the task, he then waded further into the river until the water reached his ribs, when off he shot into the deep water without hesitation. The current being so strong and rapid—the river boiling and tumbling over a rocky bed, at the rate of six miles an hour—it was impossible for the courageous and attached animal to keep a direct course across, although he breasted the waves heroically, and swam with remarkable vigour. Had he been able to steer his way directly across, the pier-wall would have proved an insurmountable barrier. As it was, the strength of the current forced him down to below where the lower extremity of this long pier abuts upon an island, the shore of which being low and shelving, he was enabled to effect a landing with comparative ease. Having regained terra firma, he shook the water from his dripping flanks; but he did not halt over a few minutes, when he plunged into the basin, and soon regained his native shores. The distance from where Grizzle took the water, to where he effected a landing on the island, was about seven hundred yards; but the efforts made to swim directly across against the powerful current, must have rendered the undertaking a much more laborious one. At the commencement of his voyage, his arched neck and withers were above the surface; but before he gained the island, his head only was visible. He reached his own-stable door—that home for which he had risked so much—
to the no small astonishment of his owner. This unexpected visit evidently made a favourable impression upon his master, for he was heard to vow, that if old Grizzle performed the same feat a second time, for the future he should remain on his own side of the river, and never be sent to the mill again. Grizzle was sent back to work the boat on the following day; but he embraced the very first opportunity that occurred of escaping, swam back in the way he had done before; and his owner not being a person to break the promise he had once made, never afterwards dispossessed him of the stable he had long been accustomed to, and treated him with marked kindness and attention.”

THE BRITISH HORSE.

Having detailed, with as much fulness as we deem necessary, the principal features and characteristics of the horses of those nations which have, more or less, held their qualities in high estimation, we now proceed to give a concise history of the English animal, and to trace the improvement of the indigenous breed of this country to its present exalted state. We may felicitate ourselves upon the fact, that the efforts of our breeders and trainers to improve the horse, have been crowned with the most decided success; for our animals are vastly superior even to the parent stock, to which we were first indebted for that new infusion of blood which has given them greater size, strength, and speed than are found in the horses of any other country.

The early history of the English horse is involved in too much uncertainty to allow us to speak with decision upon even the probabilities of his nature. It is said, however, that he was comparatively small in size, and of a wild and uncultivated form. When the island was invaded by Caesar, he found the British horses regularly harnessed to war-chariots; but it is supposed probable, that after the people had advanced from barbarism into a tolerable degree of civilisation, the use of the animal was principally diverted to domestic purposes. This supposition rises out of the consideration of our insular position, which naturally made the ocean the element upon which we were best able to cope with our foes, and superseded the necessity of establishing an armed cavalry, until contention broke out among ourselves. By the Romans, however, the character of the horse of this country must have been changed. In their cavalry were horses from Italy, Gaul, and Spain; and these crossing with the indigenous breed of Britain, would produce another race different from that which had hitherto occupied the island. In the seventh century, it is on record, that the English then made use of the saddle, and that bishops and others rode on horseback. Before this period these dignitaries of the church pursued their journeys mostly on foot, and only made use of a horse when the circumstances were of such a character as to demand it. To mark their humility, they rode mares only—the female animal being, at that time, deemed neither so handsome nor so valuable as the male.

At a subsequent period, during the Saxon sway, it would appear that an excellent breed had risen up; and that in the time of Alfred, a master of the horse was appointed to look after the breeding and the training of that animal. This is an important fact, inasmuch as it forcibly indicates the height to which the horse had now attained in the royal estimation. This officer, in every subsequent reign, was attached to the sovereign, more particularly on state occasions.

On the death of Alfred, Athelstan succeeded to the throne, and this prince received from Hugh Capet, of France, a present of several German running-horses. This, then, was the cause of another cross in the English breed; and, as the horses presented were likely to be of the very best kind, we may conclude that they had an improving influence. The animal had now attained a high reputation; for we find that Athelstan, A.D. 930, forbade the exportation of horses, except as presents to monarchs. He also laboured to improve the breed, which had already begun to be considered valuable on the continent.

About a century and a quarter later, William the Conqueror invaded England, and the success of his expedition soon produced a corresponding effect upon the breed of English horses. In his army were several Spanish animals, ridden by Norman knights; and the war-horse upon which he himself rode, was a native of Spain. The cross which took place...
with these tended greatly to raise the fallen character of the English horse for activity, spirit, strength, and beauty. After the Conquest came the Crusades, which brought the English into an acquaintance with the fine horses of Syria and Arabia, and enabled many of our barons to possess themselves of some of these species. Richard Cœur-de-Lion himself purchased two of the breed at Cyprus, celebrated for their speed and beauty. We are not aware whether these ever found their way to Britain; but about fifty years later, in the reign of Henry II., we have the first mention of an Arabian horse having been introduced to this country. In order to carry the knight of the Middle Ages, invested in all the pomp and panoply of war, a strong animal was necessary. Accordingly, spirit, as well as power to carry his rider, must have been amongst the principal qualities requisite to be obtained in the war-horse;

At this period the head of the war-horse was adorned with a crest, which, with his flanks and chest, were either wholly or partially protected by a mail covering. Indeed, the body of the animal was, in some instances, completely clothed in steel, and his bridle decorated with every adjunct of splendour that the purse of his rider could afford. Bells not unfrequently formed a part of his equipment; than which, in the language of an old troubadour, “there was nothing so proper to inspire confidence in a knight, and terror in an enemy.”

At the early part of the twelfth century, Smoothfield, or Smithfield, begins to be spoken of as a horse-market, a tournament field, and a race-course. Here horses of every description were to be seen, from the mighty and majestic charger, down to the light and sleek, ambling palfrey. Smithfield, however, has long since passed from the character of both a field and a race-course. It is no longer what it was; and whatever may be the glories of its reminiscences in the mind of the metropolitan antiquary, it will soon cease to be remembered as having been the busy locality even of a cattle-market.

Passing over the reigns of future monarchs, many of whom laboured to improve the breeds, we come to the days of James I., who was a great lover of field sports, and also a great encourager, if not absolutely the establisher of horse-racing in Scotland. When he came to the English throne, he brought, from his own country, the same passion for sports; and as he was partial to racing, he determined to try the Arab breed in this exercise. Accordingly, he bought an Arabian, for which he gave five hundred pounds, but which was not very favourably estimated by the then Duke of Newcastle, who wrote a book on horsemanship, and pronounced the pet of James worthless. This judgment so materially damaged the Arabian in the eyes of English breeders, that the Arab lost caste immediately, and none of his kind regained proper position for nearly a century afterwards.
In the reigns of Elizabeth and James, a considerable number of writers appeared on the subject of the horse, and of farriery. Blundeville, the earliest now known, and one of the ablest, describes the generality of horses in the reign of Elizabeth, as either weak or sturdy jades, adapted only to draw; with, however, some very creditable exceptions indeed. As an example, he states the fact of one of them having travelled for a wager eighty miles within the day. The great breeders of the country had been accustomed to import, for the stud, “The Turk, the Barbarian, the Sardinian, the Neapolitan, the Jennet of Spain, the Hungarian, the high Almaine (German), the Fricland, the Flanders, and the Irish Hobby.” Nevertheless, in those days, horses could not have been very numerous in England, since Queen Elizabeth experienced the utmost difficulty in mounting two or three thousand cavalry.

Throughout these early periods, as in modern times, riding on horseback, and trying the speed of horses, was peculiarly an English diversion. The country sports of hunting and hawking are of very ancient date; and our old chronicles furnish us with accounts of the constant diversions in Smithfield, then an extensive plain, where, as already observed, London citizens met, matched, and raced their horses; the superior social orders joining and taking part with the citizens.

The unfortunate Charles I. instituted races in Hyde-park; and, after him, Cromwell kept his stud; but racing did not, throughout the wars and the Protectorate, flourish as it had done in the days of James I. With the restoration of the merry monarch, racing, which had just lived a fitful season during the reign of the first Charles, was began again with spirit. At this period, with the exception of a few Arab stallions and mares, of a most uncertain lineage, introduced during the last reign, the description of horses to be met with in Great Britain, consisted of the Aboriginal race, the ponderous Norman war-horse, and the unwieldy Flanders mare, used by the nobility to drag their state-coaches, and to carry the pillions, upon which English dames were wont to jog behind their burly masters. It would be easy to trace all the variations of the horse, known in this country by the very significant names of “half-bred,” from these three sources. Of course we look for them no further back than the first introduction of Arab and Persian blood; and we find them the produce of the stallions of those countries crossed with the English, Norman, and Flanders mares. Thus, from the first, descended the old English hunter, showing all the cross-made, hardy framework of his dam—the blood-like head, and flat sinewy legs of his sire. The roadster, from the same sire, was the produce of the second-class of our native mares. As distinct classes, probably no specimens of either are now to be found, their descendants constituting the endless ramifications of all the tag-rag nondescripts, by which the drudgery of town and country work is performed.

In the reign of Queen Anne the Arabian was brought again into fashion. A Mr. Darley was the means of this; and it is to the offspring of the animal—further noticed in our next chapter—which goes by this gentleman’s name, that we are principally indebted for the breed of horses which we now possess, and which is unrivalled for strength, speed, and beauty.

The peculiar English system of breeding, essentially and usefully different from any other country in Europe, had an early commencement; but it was confined to the superior, chiefly to the sporting classes. This system has been gradually and progressively improved to the present time. Within the period of its existence we have produced specimens in every variety of the animal, bordering on attainable perfection. Such, however, it must be acknowledged, have been, even in our most vaunted periods, sufficiently scarce; and our numbers of scientific and judicious breeders have at no period formed the majority. The average, however, of English horses, has possessed a fair proportion of the English principle. Hence their being always in demand for foreign studs.

“ar the coursers of the East,” says Mr. Youatt, “might have been easily procured; a new supply of Arabian blood might have been obtained from the native country of the Barb, but French and Italians, Germans, Russians, and Flemings, have flocked to the British Isles. The pure blood of the present Barb and Arabian has been postponed, and all have deeply drawn from that of the thorough-
bred English horse. This is a circumstance with regard to which there is no dispute. It is a matter of history, and it is highly creditable to our sporting-men and breeders."

This national principle of horse-breeding consists in matching the horse and mare in respect to size, substance, blood, and a certain conventional symmetry, so as to obtain a form in the foal, in which may subsist a union of strength and ability for labour, with the powers of activity and speedy progression. We proceed on the principle that, generally speaking, "like produces like," although to this rule, like most others, exceptions appear.

As we imported foreign horses, invariably improving upon those models, so we originally imported the art of farriery and veterinary science from the schools of Italy and France, improving upon them likewise. In the earlier periods of which we have been treating, the farriers of note, and the riding-masters in England, were generally Italian and French. They were, indeed, sufficiently barbarous and unenlightened; but our native artists were inconceivably more so, when the length of time is considered, through which their art had been in universal practice in all its branches.

**Ponies and Galloways.**

There is still one breed of horses, which may be considered aboriginal in Great Britain, and which is the Shetland ponies—called Shelties by the natives of Scotland. The description of these astonishing little animals almost exceeds belief. They are less in size than the Orkney horses; for some are but nine, others ten hands high; and they are thought big horses if eleven; but although they are so small, they are full of vigour and life. Some of the smaller sizes often prove the strongest. Many of them are so diminutive that an able man could lift them up in his arms; yet it is said they will carry him and a woman behind him eight miles forward, and as many back. Summer or winter they never enter a house, but, in some places, run upon the mountains, in troops; and if, at any time, in winter they are straitened for food, they will descend from the hills when the ebb is in the sea, and feed upon the sea-weed. Winter storms and scarcity of food, bring them frequently so low that they do not recover their strength till about the end of June, when they are at their best. They live to a considerable age, reaching twenty-six, twenty-eight, or thirty years; and are good for riding at twenty-four. Those of a black colour are esteemed the most capable of endurance. The pied often prove not so good. The smallest of the breed are in the northern isles of Yell and Unst. The coldness of the air, coupled with their scanty provender and hard usage, may influence their growth to a large extent; for, even if bigger horses are brought into these islands, their offspring will, in a little time, degenerate.

After viewing these little shelties, which are almost of as much importance to the otter of their country, as the fleet Arabian of the desert is to his master, we feel lost in admiration at the wisdom of that Power who has adapted animals just to suit the situation in which they can be of most service to man.

We, now and then, see some of these small creatures in the southern parts of England, harnessed to a light garden chair, or sometimes carrying an almost baby rider. There are several of them in Windsor-park. It would be curious to watch the stock of these little animals, and to see what improvement, in size, a richer pasture would have upon the smallness of their original breed.

Besides the Shetland, there is the Highland pony, which is not pleasant to ride, except at a canter. His habits make him hardy, for he is rarely housed in the summer or the winter. The Rev. Mr. Hall says, that when these animals come to any boggy piece of ground, they first put their noses to it, and then pat on it, in a peculiar way, with one of their fore-feet; and from the sound and feel of the ground, they know whether it will bear them. They do the same with ice, and determine, in a minute, whether they will proceed.

The Welsh pony is one of the most beautiful little animals that can be imagined. He has a small head, high withers, deep, yet round barrel, short joints, flat legs, and good round feet. He runs with great speed; has a wild and roguish look; and is just such an animal as a spirited girl of sixteen would delight to be perched upon. When seen tossing his mane on the sides of his native mountains, no quadruped can be more attractive. The Welsh ponies are said to be indebted to the celebrated.
Merlin, for their form and qualities. They will live on any fare, and can never be tired out.

The New Foresters, notwithstanding their Marsk-blood, are generally ill-made, large-headed, short-necked, and ragged-hipped; but hardy, safe, and useful; with much of their ancient spirit and speed, and all their old paces. The catching of these ponies is as great a trial of skill, as the hunting of the wild horse on the Pampas of South America, and a greater one of patience.

A large number of ponies, of little value, used to be reared in Lincolnshire, in the neighbourhood of Boston; but the breed has been neglected, and will, probably, be suffered to die out.

The Exmoor ponies, although generally ugly enough, are hardy and useful. A well-known sportsman says, that he rode one of them half-a-dozen miles, and never felt such power and action in so small a compass before. To show his accomplishments, he was turned over a gate at least eight inches higher than his back; and his owner, who rode fourteen stone, travelled on him from Bristol to South Molton, eighty-six miles, beating the coach which ran the same road.

There is, on Dartmoor, a race of ponies much in request in that vicinity, being sure-footed, and hardy, and admirably calculated to get over the rough roads and dreary wilds of that mountainous district. The Dartmoor pony is larger than the Exmoor, and, if possible, uglier. He exists there almost in a state of nature. The late Captain Colgrave, of the prison, had a great desire to possess one of them of somewhat superior figure to its fellows; and having several men to assist him, they separated it from the herd. They drove it on to some rocks by the side of a tor, an abrupt pointed hill—a man following on horseback, while the captain stood below watching the chase. The little animal being driven into a corner, leapt completely over the man and horse, and escaped.

The horses which were formerly used in Devonshire, and particularly in the western and southern districts, under the denomination of pack-horses, are a larger variety of the Exmoor or Dartmoor breed. The saddle-horses of Devonshire are mostly procured from the more eastern counties.

It was, we believe, Buffon’s opinion, that all horses have been derived from one common stock, and the difference between them in point of strength, size, speed, &c., has been accomplished only by food and climate. This, however, has been disputed; and the question may be difficult to answer, whether the pony and large English horse were, or could be, originally from a common stock. It is, however, not impossible that they might have had one common origin; for if we reflect on the changes which the different modes of feeding effect in the condition of animals, it is not so improbable as it may at first appear.

Without pausing to discuss the question whether a horse will represent in size what it feeds on, we adduce a circumstance which has some bearing upon it, and which fell under the personal observation of the gentleman to whom we are indebted for it. His father had a mare that brought him no less than fourteen colts, and all by the same horse, and not one of which, at three years old, was under seventeen hands high. She was in the fifteenth foal by the same horse, when he sold her to a neighbouring farmer, reserving the foal, which was to be delivered in a twelvemonth.

At her new master’s, she was comparatively starved, and she came back at the expiration of the year, so altered as scarcely to be recognised. The foal, four months old, was very small. The little animal was put on the most luxuriant diet, but it did not reach more than fifteen hands high, at the expiration of the third year.

Dr. Anderson says that there was once a breed of small elegant horses in Scotland, similar to those of Iceland and Sweden, and
which were known by the name of Galloways. The best of these sometimes reached the height of fourteen hands and a-half. One of this description he possessed, it having been bought for his use when a boy. In point of elegance of shape, it was a perfect picture, and in disposition was gentle and compliant; it moved almost with a wish, and never tired. The Doctor rode this little creature for twenty-five years; and twice, in that time, rode a hundred and fifty miles, without stopping, except to bait, and that not above an hour at a time. It came in, at the last stage, with as much ease and alacrity as it had travelled the first. The Doctor says, he would have undertaken to have performed on this animal, when it was in its prime, sixty miles a day for a twelvemonth running, without any extraordinary exertion.

A Galloway in point of size, whether of Scotch origin or not is uncertain, started when coaches were running, from London with the Exeter mail; and, notwithstanding the numerous changes of horses, and the rapid driving of that vehicle, it arrived at Exeter—one hundred and seventy-two miles—fifteen minutes before the mail. A gentleman who saw this animal about twelve months after his wonderful performance, described him as being wind-galled, spavined, ring-boned, and a lamentable picture of the ingratitude of man towards a willing and faithful servant.

In 1754, Mr. Corker's Galloway went one hundred miles a-day for three successive days, over the Newmarket course, and without the slightest distress.

A Galloway belonging to Mr. Sinclair, of Kirby-Lonsdale, performed at Carlisle the extraordinary feat of one thousand miles in a thousand hours!

Galloways have greatly decreased in point of numbers. Many of those which are now in use, are obtained either from Wales or the New Forest. The Galloway is supposed to have originally been of Spanish extraction.

CHAPTER III.

GENERAL OBSERVATIONS ON THE HORSE; THE SUPPOSED DEGENERACY OF THE RACING BREED, ETC.

Before considering our Racers, and their kindred breeds in this country, it may be as well to make a few general observations on the racing animal, and the supposed deterioration of his blood. The subject is one of great interest, and merits the thoughtful consideration of all those who are more especially connected with the genus equidæ. Some have supposed that the deterioration may have arisen from the fashion of the present mode of breeding for length of stride, and for short races. This, however, might be easily altered by our present stock, without proceeding to the necessity of employing fresh blood to invigorate it. There are others, again, who insist that nothing less than a national establishment will prevent our horses from becoming sorry jades.

The English horse is so identified with the glory of the country, that we could hardly look upon any one as possessed of patriotic feelings, who would see, without a sigh, the degeneracy of our native breed.

There is, at present, one circumstance, however, which places us in a novel situation in respect to the horse, which time only can develop. We allude to the effect that railroads may have had upon the breed. It is a well-known fact, that, at the commencement of the railway system of travelling, many spirited coach-proprietors gave almost hunters' prices for their cattle, and that there was a regular demand for horses of any size for the use of coaches. This traffic having in a considerable degree ceased, it will become a matter for consideration whether there will be any stimulant for breeding sufficient to carry it on with profit and spirit; or whether it will be abandoned, and treated with indifference.
much natural speed, stoutness under severe exertion, with limbs and feet peculiarly adapted for moving rapidly on a hard surface. It would be puerile to bring from so great a distance, such ill-shapen and attenuated creatures as those now usually imported under the name of Arabians; or to employ persons to purchase, who have not had experience of the best horses under severe exertion. They would search in vain amongst Orientals for those properties which are acquired under a system of continued selection. Looking only for natural qualities, they should select animals as nearly in a state of nature as they can find them; having good symmetry, a full amount of muscle, and whatever natural speed the best animals of the best race are found to possess.

When brought to England a further trial should be made. In this we should be content with a degree of speed which is natural, and an amount of structural power as nearly natural as could be procured. The offspring of these small horses should be tried in each succeeding generation; and we should be satisfied, for a few years, to see the natural speed of the race gradually augment; retaining only for breeding such as went through their trials satisfactorily.

It would be folly to buy horses of large structure in the East, as such would be found to have less speed than the smaller ones; while factitious structure can be given by ourselves with only too much facility.

Whenever the public shall become alive to the deteriorated condition of our saddle-horses, and anxious to obtain such as are more useful, the first step must be a recurrence to nature for those properties which art has destroyed. It has been shown that, in the absence of fresh blood, the elongated skeleton of the modern racer can only be shortened by a process which would render him a starveling. The character of the whole race has been reduced, in this respect, to a common level. Some individuals may be more compact than others; but all have lost something which fresh blood only can restore. If we rear them at a reasonable expense, their growth is stunted—if on rich grass, they lose their speed. Whether we try to renovate this exhausted race, or substitute another, the objects we seek are a more compact form and greater
vigour; and these can only be found in horses which are nearer to a state of nature. So long as individual differences in a race enable us to correct individual defects, we may dispense with fresh blood, but no longer.

A national establishment, having selected horses from amongst a fine race, distinguished by their symmetry, their natural speed, and full amount of muscle, should carefully observe how far the artificial properties afterwards given to the race, diminished its natural ones. A mass of facts would, after some years, be obtained and recorded, calculated to throw, for the first time, a steady light on the distant, as well as proximate, consequences resulting from factitious causes. These facts are not likely to be collected under any system less permanent and comprehensive than one under the control of a national establishment. Its stock should be divided into two portions; both should be placed under the influence of continued selection for speed and stoutness; but one should be maintained at a structure as nearly natural as possible. With such conflicting properties as speed, vigour, and great structural enlargement, a reserve of more natural animals cannot be dispensed with. The enlarged portion of the stock should again be divided into two classes, one being kept for breeding, the other for working. The size of the former should be allowed to become as large as is required to enable it to produce animals sufficiently powerful for working; every effort should be made to keep down the stature of the breeding animals to that point which suffices, by the aid of rich food, to produce working animals sufficiently powerful; increasing the stature of the race as little, and that of the individuals as much as possible. In breeding horses of the best race, it might be found desirable to have one portion of less speed, but more muscular, than the other, in order to meet that variety of demand which necessarily exists in a highly civilised nation. There should be a certain amount of foreign blood in the horses of our heavy cavalry; but foreign horses, having a degree of speed which is incompatible with much muscular power, are not so well calculated for heavy cavalry as such as have less speed, but more muscular and constitutional power. Mambrino, Sweetwilliam, or Sedbury, were better fitted for producing proper stock for cavalry than Sharke. This animal was more advanced by art than the earlier horses as respects speed; but he was not so well calculated for enabling us to produce powerful saddle-animals. If a foreign race is to assist in the production of our heavy cavalry horses, it should possess as much structural power as can be combined with a sufficiency of action, vigour, and sustaining strength.

The natural qualities of the horse are found nearest perfection when they are in a condition the least removed from one of nature. Artificial structure is obtained by rich food, and artificial speed by continued selection. The course of the breeder is easy, so long as it is in one direction; that is, in advance. When, however, the form of a whole race has become deteriorated, the symmetry, which is lost, can only be recovered by going back to nature. A national establishment would, in this case, renovate the enlarged portion of its stock by having recourse to the animals whose stature had been little increased. Such an institution should ever be at work, preparing smaller animals, by means of trials and continued selection, for being crossed when required with that enlarged portion of its stock which, from time to time, became deteriorated. The smaller animals, until wanted, should be kept in a state of nature as nearly as possible. They would thus retain their vigour while acquiring all the advantages derivable from continued selection; they could be maintained at the least possible expense; at one which the sale of the annual draughts would nearly or wholly repay.

If a new race were to be formed, under the system we have now recommended, capable of running long distances, and carrying considerable weight without distress, premiums might be again granted to the winners of certain feats upon the turf. To attempt to make modern racers run longer distances, or carry more weight than at present, would be both cruel and useless. A national establishment, undertaking to form a new race of foreign horses, could not be said to succeed, unless it supplied the country with as swift, stout, and powerful animals as were the earlier racers. Knowing accurately the powers of the new race, it could point out the nature of the
running for which premiums might properly be granted; and great tasks might again be performed on the race-course without any of the cruelty which attends the present modes of running.

The stallions, whose stature had been adequately enlarged in the establishment for supplying the demand of the farmers in the great breeding counties, should be let out under strict regulations, or, in those counties, maintained by the establishment in a condition best calculated to preserve their vigour. Mucilaginous food, and other expedients, had recourse to, by private individuals, to make the animals very fat, should not be resorted to. The stallions of a national establishment should make their way to public favour by the goodness of their stock. No horse should leave the establishment, as a stallion, labouring under any essential defect. If a public establishment supplied the breeding counties with the best class of stallions at a cheap rate—bred within its own precincts—the public would be enlightened by example; and, becoming gradually accustomed to see the best forms, would no longer be satisfied with bad ones.

In determining the utility of some such plan as here proposed, the reader will do well to ask himself the following questions. Is there a strong disposition in every fine race of the horse, whose structure has been enlarged by un自然地 rich food, to become either coarse or weedy? Are the plans adopted on the race-course, to prevent coarseness, more than palliative? And are not some of them objectionable? Is it not better to recur to nature, when art has disposed a domesticated race of horses to coarseness, than to such a palliative as that of breeding on one side from old parents? Is not this substituting weediness for coarseness? If we adopt a system under which both coarseness and weediness are avoided, by recurring, when necessary, to fresh blood, we should be able to rear and work horses at the least possible expense. Under this system any essential loss of vigour would be instantly repaired by the most economical means. In maintaining vigour in a race of horses without coarseness, we should have laid the best foundation for giving to it those artificial qualities which result from annual trials, and continued selec-

It is in our power to modify greatly the acquired, as well as the natural, properties of Oriental horses; but we cannot combine the highest degree of transient speed with the compact skeleton and muscular power displayed by the earlier horses, and required when great distances are to be traversed, or much weight to be carried.

The practical utility of the projector's plan and speculations may create doubt in some minds as to the propriety of ever adopting them to the extent of his views. They may, however, stimulate inquiry, and, at some period, be productive of all the benefit the most sanguine may anticipate. It is a subject of vital importance, and of grave deliberation.

We hear of much despondency expressed that our breed of horses will die out, and that its advantages, some of our continental neighbours are of opinion, will not long remain with us: they are fully aware of the source whence we derived this superiority, and, in consequence, have endeavoured to establish races on the English plan, which, together with a more careful selection of stallions and mares than we observe in England, will very soon, they say, enable them to excel us; and they anticipate a day, not very distant, when we must send to the continent, if not for speedy, at least for sound horses. This hint about soundness may be worth attention; but, for the rest, there can be little to apprehend.

The following account for the demand of the racing blood of this country, would, however, make it appear that, in foreign countries, the English race-horse was, at no distant day, held in great estimation.

England, where, during the last century, the improvement of her breed of horses has been cultivated with unwearied zeal and a lavish expenditure, is now reaping a golden harvest in return for her enterprise and spirit. Purchasers arrive from the four quarters of the globe. America has taken up the speculation with an ardour worthy the scion of "the old country," and France, more especially under the reign of Napoleon the Third, seems to think it even of national importance to encourage the breeding of horses upon a better principle than that of crossing the Flanders mare with the Norman stallion. With the view of turning the attention of the
French farmer to a new source of rural industry, the royal breeding stock in Normandy is conducted on a scale of which we have no example in this country. Their stud of stallions is enormous; and during the season, many of the best sort are sent all over the country.

Germany purchased largely of our best blood: Holstein, Belgium, Denmark, and Russia have bought from us: but no purchasers formerly came to the English market, or evinced the talent and spirit of the Americans. France will never be a vent of any consequence for our racing stock, as such. Her government will import our stallions, and encourage the speculation in others, as the means of introducing a better description of horse for general use, particularly for cavalry; but she will not offer, by the gift of public money, any inducement for the introduction of race-horses into that country.

We have no fear, however, of France rivalling us in the breed of horses, so long as we have the law of primogeniture, and so long as France is without it. The expenses of the race-course will never be supported in France in the same way as in England, on that very account. In a country like France, where property is so divided, and in a country like England, where money is in such masses—the race-course being a luxury as well as a pleasure, becomes the employment of the nobility of the land: the law of primogeniture preventing the division of estates, secures, at once, the experience and the means of perpetuating the breed of horses of the first quality, from generation to generation; and this is one of the causes of our superior breed of horses.

In fact, France does not require such a breed. She has, comparatively speaking, very few customers for thorough-bred horses, which would rather encumber than be useful to her. Beyond the army and the court, there are not many Frenchmen but would be content with a moderate-priced horse; and, we believe, would rather avoid the extra care and attention which a higher-bred animal might subject them to. The French, as far as our experience goes, are an economical people, not likely to encourage any expense which they possibly can do without; and therefore are perfectly contented with their present breed. There are no hounds kept in the provinces, because there are no primogeniture estates of twenty thousand pounds a-year to support them; there are no subscription packs, for the same reason that there are no private ones: property is so divided and subdivided, that if it secures comforts, the people are satisfied, and are too wise to embark in anything which they deem extravagant. There is no encouragement to stimulate the breed of hunters; and the breed of blood horses will, we suspect, remain limited, rather than be greatly extended.

We avail ourselves of the following description of a breeding stud, which will confirm the above observations, and show to what extent the breed of the English race-horse was, not many years back, kept up by our native gentlemen sportsmen.

Within a few miles of Thetford, in Norfolk, and almost adjoining each other, were situated two of the most celebrated breeding establishments in England—Riddlesworth and Laxton; the former, the seat of Mr. Thornhill; the latter, of his grace the Duke of Grafton. The proudest feature in the social condition of the land we live in, is, that the promotion and support of objects of national importance which everywhere else is looked upon as the business and peculiar province of a government, either originates in individual enterprise, or is the result of public spirit, supported by private wealth or influence. Two princely instances of this are before us. Here a national business—it is such, in fact, because no other country possesses the material, or the knowledge of its use—which from its nature is not suited to the merely professional man, is conducted with all the care and skill that could be brought to bear upon any undertaking solely embarked in for the purpose of a profitable return.

The Riddlesworth stud consisted of thirty mares. In loose boxes were three of Mr. Thornhill’s yearlings, about to be sent to Newmarket. A bay colt, by Emilus, out of Mercy, attracted considerable attention on account of its size; it was a horse in all but the name. Some Russians who visited Riddlesworth, absolutely refused to believe it, till they looked into its mouth. The second was a chesnut colt, by Sir Patrick, out of Mangle-wurzle, with size and substance for a four-year-old. The third,
a bay colt, brother to Mendizabel, by Merchant, out of Mismomer’s dams. These three yearlings averaged, each, fifteen hands two inches high!

As far as the example of these yearling colts go, there can be no cause for suspecting degeneracy; for, with their immense growth, they had substance as well as height—one of which might be taken for four years old. If these splendid and gigantic animals had had justice done them, they would not have been put to severe work before five or six years old; yet they were going into training at Newmarket directly. Where there was so much strength and substance developed at so early a period, surely it cannot be unnatural to suppose that, if time were given for the consolidation of those powers, instead of racing them at two years old, we should not have to deplore the want of durability in our racing-stock. If we sin against nature, however, we must take the consequences; for we can never do that with impunity.

It might be interesting here to draw a comparison between the English racer and the parent stock, as to the difference between them in point of size. The principal cause of this, perhaps, arises out of the superior kind of food which the one receives to the other, and which thus increases the structural economy of the animal. We will, however, rather proceed to give a description of two of the most beautiful Arabs ever seen in this country. They were a present from an Eastern prince, the Imam of Muscat, to his majesty William the Fourth, and show the difference, in a most striking manner, of the present breed of English racers to that from which they are derived.

The first was a black stallion, standing fourteen hands three inches high, branded M on the off-quarter. This horse was the most esteemed of the two; his colour, in Arabs of the highest class, being rarely or ever met with. Years were consumed in selecting this pair sent to his majesty, and no limit put upon their price. Great as the difficulty has ever been to convey a just idea of the horse with the pencil—to put upon paper, words to effect such a purpose, is a ten times more hopeless task.

The first impression that the sight of this little, unpretending animal, made upon one, was anything but such as are in accordance with our usual anticipations. The issue was precisely such as one experiences in contemplating a highly-finished picture—the more you gaze upon it, the more its beauties become developed. In this country, we are by no means familiar with the Arab—many have not even seen one; but if the portraits with which every sportsman is familiar of the Darley or Godolphin Arabians, be faithful delineations of the animals they profess to represent, the whole model of the Arab horse, as shown by the one in question, differs toto calo from them.

“Here I had before me,” continues the author of this description, “one, selected by a prince whose subjects have ever been celebrated for trafficking in the purest blood of the desert. I could not doubt his claim to legitimacy. I have said his height is fourteen hands three inches; his form so angular, that at the first glance it seems to defy all claim to symmetry. The whole character of shape and bearing is closely allied to that of the deer. When you come to a minuter examination of the parts, individually, then you are convinced how pure the fountain must have been whence such blood was obtained. The head of this horse can be likened to nothing but exquisitely chiselled marble; there is literally no flesh upon it; it is marble, too, to the touch. The eye is small, but clear to transparency; the cheek-bones are prominent; and there is a fixedness about the ears that helps you to think you are really looking upon the work of the sculptor. The jaws stand very far asunder, the nostrils are large and high, and the windpipe is of an extraordinary size. The neck is light, and set on similarly to the deer’s: the shoulders more fleshy and upright than suits our taste; but, below the knee, the legs are perfection; you find quite as much bone as in the largest sized English blood-horse, and the tendons are in your grasp like iron. His carcass, without being very full of substance, is round, and tolerably deep; his quarters, what we express by vulgar. His thighs are very thin and sinewy, his loins narrow, his hocks perfectly clean and slightly inverted—he is what we call ‘cat-ham’d.’ The tail is well set on; the dock small; the hair fine and scant, giving it the appearance of a mule’s more than that of a horse. His shanks are short, and hard as
The pasterns flexible; the hoofs singularly hard, but healthy; and the feet open and roomy. You read his temper in his eye; he is a light-hearted animal, without the slightest taint of vice.

The other stallion, a bright bay, is described almost in the same words. His head is less perfect, and the bone smaller; but his quarters are fuller, and more softened down by the swell of the muscles. His back, which, like the other, is rather inclined to be hollow, is not more than eight or ten inches from hip to shoulder. "I never saw a pony’s so short. His height is, as nearly as possible, the same as the black; in middle piece he has the advantage. They were both brought out for me, and I saw them in all their paces. In their action, as in their lean, spare forms, you detect nothing superfluous; it is quiet and graceful, and entirely without any expression of exuberant exertion. Utility is the characteristic of the Arab horse. I can imagine him going for days together without fatigue; nature intended him for this, and she has fitted him for endurance. The impression of his extraordinary speed was long a vulgar error, which is now fast exploding. No Arab that ever trod the sand, could live in company with an English race-horse, weight him for inches, or after any fashion you will: with the size of a Galloway, you cannot have the stride essential to great velocity. Speed, regular and long sustained, no doubt he possesses: our blight of degeneracy is yet unknown to the desert-bred. Before I part with these horses, I cannot but regret that one or two of the mares at Hampton Court were not put to them. Surely nowhere could the experiment have been so properly made. That their stock in the first, or tenth generation, could compete with Emilius or Sultan, no one supposes; still they are crystal streams, fresh drawn from the spring, whence it is acknowledged we derived the fertilisation of our own turf. If only to trace its progress, it might be a useful lesson, probably a guide of great importance."

In giving the description of these two very extraordinary high-bred Arabians, selected by a prince who spared no expense, and brought from his own dominions, which is a country also renowned for the breed of horses we cannot but suppose that these specimens were of the very highest caste, and the perfect representations of their kind.

The gentleman to whom we are indebted for the description of these two beautiful small Arabs, says that there is no resemblance whatever between them and the portraits of the Godolphin and the Darley Arabians. This, no doubt, is very true; for these were horses of considerable size and power, and their immediate descendants became racers. To them, however, the English breed is so much indebted, that, under the head of the English Racer, we shall have something to say of both the last-named horses.

We shall now return to the stud at Riddlesworth—an establishment which, although only in the hands of a private English gentleman, is sufficient to show what sort of personages we are indebted for the superiority of the English horse, and for the beauty and speed with which wealth and art have united to invest him.

Our first duty is to introduce our readers to the sires of the three yearling colts, of which we have already spoken, and which averaged fifteen hands two inches high. The following is the description of an accomplished sportsman who visited them.

"I now followed my obliging conductor (the stud-groom) for a visit to the stallions. Their boxes, each with a large walled yard attached to it, are close to his dwelling-house, around which, also, lie various commodious houses for the young stock when it is first taken up, previous to being taken away by the purchasers, or sent for training to Newmarket. The stallions all lie out—that is to say, their boxes are left open; and unclothed, and untouched, they have the run of the yards, night and day, till generally the second week in December. They are then shut up, groomed, and put into condition preparatory to the approaching season. The first I saw was Merchant, by Merlin, out of Quail, by Gohanna. He is a powerful, short-backed chestnut horse, and his stock have shown well. He is a favourite at Riddlesworth, probably on his sire’s account, Merlin having ever been high in Mr. Thornhill’s estimation.

"Next to him came St. Patrick, by Walton, his dam by Dick Andrews. This is a very
time-looking chestnut horse, hired, I believe, from Mr. Dodsworth. He is light topped, with a good deal of the character of Actaeon about him: his frame is beautifully moulded; his legs, which have tasted the iron all round, well under him; fine withered, deep gaskined, with thighs and quarters quite perfect. He is short in the pastern, a quality pronounced, by most men, as demanding praise, but as little esteemed by me as its opposite, long.

"In the post of honour, the dwelling nearest to himself, Tyler introduced me to the steed whose own performances, and those of his descendants, place him without any parallel in the annals of British racing—Emilius, by Orville, out of Emilius, by Stamford, grandam by Whiskey, out of Grey Dimmont. 'And this,' said I, 'is Emilius!' as a rough-coated animal, with an eye like a star, came snorting up to me. He was quite en deshabilite to receive company, as it was evident he had been recently indulging in a roll among the mire of his exercise-paddock. The moment I laid my hand upon his shoulder, he stood still, looked complacently upon me, and, notwithstanding his having been surprised a little mal-apropos, accorded me a reception quite in keeping with his acknowledged high breeding. Taking this horse as the standard of perfection of the English blood-horse of the nineteenth century, I will state, as well as I can, the result of a very careful examination of him, and thence draw such inferences as are relevant to my present purpose. He was then in his sixteenth year; and his height over fifteen hands two inches. In colour he was a rich blood-bay (when in his spring form), with four black legs. He was all over sound, and without blemish, save in his off fore leg, with which there seemed to have been something amiss below the knee. Probably the most skilful anatomist would fail in discovering one point of his symmetry faulty. This latter phrase may require explanation: what I mean by it is, that although his frame should be pronounced perfect, as it was; that in its symmetry, the harmony of each part with the whole, the fitness and relation of every point for its assigned function, defied criticism. You saw before you a form moulded for speed and strength, as the imagination of the most experienced painter would pourtray it. We know that he was swift and strong—let us see if his physical development agreed with the idea affixed by the eye for power.

"'Tyler,' I inquired, 'have you a morsel of string? Never mind,' seeing that he was going to procure it for me at his house. I removed my watch-guard.

"'Ah!' said he, seeing the use to which I was about to apply it, 'you are going to measure his leg I see: well, I have not seen such a thing done since the time that his royal highness the Duke of York was staying at Riddlesworth. The duke, I remember, came one morning, and took the size of Merlin's near fore-leg just under the knee, and its circumference was full nine inches and a quarter. Now, sir, I like Emilius's leg much the best: it is shaped, as I call it, like a fiddle, with the strings standing well out from it, the way that a horse's muscle and sinew should do.'

"Having carefully taken my measurement of his near leg, I entered it in one of the leaves of my pocket-book. It is now before me, and gives the circumference at exactly eight inches and a-half. This was a little less than the measurement of the off-leg. I need hardly remark, that the apparent advantage on Merlin's side is easily explained, if his limb was rounder, and consequently less oval than that of Emilius. This would give him, however, no actual superiority, the shape of the bone and sinew of a horse's leg being an oval—shallower, of course, as it extends from bone to muscle. For this horse, I was given to understand, Mr. Thornhill refused eight thousand pounds.

"Nothing could be more characteristically English than the establishment at Riddlesworth. Tyler, the stud-groom, was an honest, obliging yeoman, with his mind on a level with his calling. The stock which he produced and reared during a long period of superintendence and care, was the best evidence of his fitness for such occupation. I spent a few minutes in his cottage, and it was just the head-quarters in which I should have expected to find him. Everything was scrupulously neat; all the comforts that his condition could require, were there in abundance; and the elegancies were in perfect accordance. The walls were decorated with the most cele-
brated feats of the white and scarlet. There was Sam winning the Derby in 1818; Sailor, victorious for the same stakes in 1820; a fine plate of Orville; and one of Herrings admirable likenesses of Emilius. In front of his dwelling ran a sparkling stream, and just beyond it was a moving zoological panorama, such as no nobleman in the land could show, and which may be called a description of the once celebrated stud at Riddlesworth.

In France, as already observed, there is not the same inducements as in this country for fostering and encouraging thorough-bred horses. Napoleon I. used to send studs into the different French provinces, to maintain the highest breed. One of these, at Auch, capital of Gascony, consisted of horses of various countries—the Arab, Barb, &c.; and among these was one which attracted much attention. He was an English thorough-bred, standing full sixteen hands high; was called Romulus, and was said to be above thirty years of age. He had all the appearance of age, having lost his flesh; but there was his eye and noble forehand, which indicated both dignity and high breeding. There was nothing to resemble him. The other stallions were full of flesh and pretty; but the English horse, for size and speed, never could appear to more advantage than when in such company. They certainly were handsome and beautiful to look at; but Romulus had the same appearance of nobility and dignity over his tribe, as may be supposed to have been possessed by John P. Kemble, in Coriolanus, over a common actor.

We have spoken of the division of property in France being very minute; and in Gascony, especially, most of the farms are very small, and cultivated chiefly by their proprietors. In many of these patriarchal abodes will be found the great-grandfather, surrounded by a portion of his descendants, at the same fire; for here the daughters bring their husbands home; and it is a pleasing sight to see them all engaged in one general interest and pursuit: the young girl handling a pitchfork, and filling the cart, with as much animation and zeal as her brothers.

"England, with all thy faults, we love thee still."

Here we see the large broad hand, and the hale complexion of wholesome labour! We turn our thoughts to Manchester, to Sheffield, Birmingham, &c., and the thin, pallid, emaciated appearance of their inhabitants; and we never feel the contrast so strong between the happiness of the followers of agriculture, and that of those engaged in manufactures, as at the time when we compare the harmony and quiet incident to rural pursuits, with those of the city. With the condition of riches we have here nothing to do. It is of the conditions of men we are speaking; and what we are mostly thinking of, is the barn with its wheat; the yard with its dogs, cows, pigs, and poultry; the fields, and the horses.

Since the days of Napoleon I., we should think the breed of horses may have, in some degree, improved in France, as a tolerable sprinkling of English mares would have been left in that country by the army of occupation; and a long peace no doubt enabled the French government to avail itself of all opportunities to improve their breed. It is therefore natural to suppose that her cavalry and artillery may now be better horsed than they were. Hunting, however, is not a popular amusement in France. The Revolution took away the game-laws, and the rights of the Seigneurs; nor would the present race of French farmers submit very quietly to witness their lands traversed by dogs and a field of horsemen; therefore, we do not suppose that there is any probability of hunters being wanted beyond the royal chases.

England is therefore so differently situated to France, that what may suit one country, and, in its effects, may be beneficial, to the other might be considered a nuisance. A farmer, in England, surrounded by the squirearchy of his neighbourhood, and partaking of the joys and amusement of the chase, thinks nothing of the damage which a field of horsemen and dogs may do to his corn-crop; believing he may be repaid for the damage done by their encouraging the demand for horses, of which he is himself the breeder. However, if he does complain, and there is reasonableness in the demand, there is always wealth enough, and we believe liberality enough, to indemnify him for any damage he might sustain on account of the hunting establishment; consequently he becomes a partner and preserver
of the sport, in protecting the foxes, so essential to the amusement of the chase, and is looked upon as a favourite in his aristocratical neighbourhood—a circumstance which insures to him respectability and position.

In France, where, comparatively speaking, there is little disproportion of wealth, it would be, we think, impossible to create any hunting establishments that would be of a nature sufficiently large to be an encouragement for superior-bred horses. As to breeding these for the turf, we believe there will be a very few studs of thorough-bred horses kept. Looking, then, at France in this view, we do not think she will take the palm of breeding the best horses from us. Neither do we think such horses necessary for France; if she obtain a good breed, it is sufficient for all useful purposes, without straining after that which, without inordinate wealth, might prove an incumbrance rather than an interesting possession.

CHAPTER IV.

BREEDS OF ENGLISH HORSES.

THE RACER.

Before entering on our description of the Racer, we will briefly trace the rise and progress of the English race-course, which has long enjoyed a world-wide renown.

It has been customary, says the elder Randal Holme, one of the city heralds, time out of mind, upon Shrove Tuesday, for the Company of Saddlers of the ancient city of Chester, to present to the drapers a wooden ball, embellished with flowers, and placed upon the point of a lance.

Mr. Lysons, in his Magna Britannia, mentions some old articles of a race, for two bells, among the corporation records, the earliest date of which was 1512.

This ceremony was performed in the presence of the mayor, at the cross in the Roody, an open place near the city. "But this year of 1540," continues Holme, "the ball was changed into a silver bell, valued at three shillings and sixpence, or more, to be given to him who shall run the best and furthest on horseback, before them, on the same day, Shrove Tuesday."

In 1610, Mr. Robert Ambrye, or Amory, ironmonger, sheriff of the City of Chester, at his own cost, did cause three silver bells to be made, of good value, which bells he appointed to be run for with horses, "upon St. George's day, upon the Roode Dee, from the new tower to the netes, there turning to run up to the water-gate; that horse which come first there to have the beste bell; the second to have the seconde bell for that year, putting in money and sureties to deliver in the bells that day twelvemonth." The other bell was run for on the same day, upon the like conditions. These trophies were taken to the course with much pomp and ceremony. Chester races are now held the first week in May, which comes as near the original time (old St. George's day) as possible.

These bells were denominated St. George's Bells, and, in the last year of the reign of James I., 1634-5, John Brereton, innkeeper, Mayor of Chester, first caused the horses entered for this race, then called St. George's race, to start from the point beyond the new tower, and appointed them to run five times round the Roody; and, according to the younger Randal Holme, "he who run the last course, or trayne, received the bell, worth eight or ten pounds, and to have it for ever, which monies were collected of the citizens for that purpose." By the author's having added that the winner of this race was to have the bell for ever, is implied, that it had been formerly used as a temporary mark of honour by the successful horseman, and afterwards returned to the corporation. This alteration was made April 23, 1624.
Sir Thomas Chaloner, who wrote in the early part of Elizabeth's reign, mentions Henry VIII. as a great admirer of horses, and of his having imported some from Turkey, Naples, Spain, and Flanders, to improve the English breed.

John Northbrook, a puritanical writer, in the reign of Queen Elizabeth, who, though very severe against cards and dice, interludes, and other idle pastimes, allows of horse-racing—a proof that it was no uncommon amusement at that time, when it was considered as a liberal sport, practised for pleasure rather than profit, without the least idea of reducing it to a system of gaming. It is ranked with hunting and hawking, and opposed to dice and card-playing, by an old Scotch poet, who laments that the latter had, in a great measure, superseded the former; and Camdenius, in 1590, says that tilting, or the quintain, is used instead of horse-races, which, he adds, are grown out of fashion.

Before the reign of James I., trials of speed were not practised, as at the present day; nor were any horses kept solely for the purpose of running at stated seasons. It is, however, certain that this comparative mode of ascertaining the goodness of horses, was not only, previously to this period, known, but that private matches were made between gentlemen, who, relying on their own skill, rode their own horses.

Soon after the accession of this monarch, who was "inordinately attached to the sports of the chase," public races were established; and particular horses becoming known for their swiftness, their breed was cultivated, and their pedigrees recorded with the greatest exactness. It was now that they began to be trained expressly for the purpose, attention being paid to the quantity and quality of the animal's food, physic, sweats, and clothing; the weights, also, which seldom exceeded ten stone, were rigidly adjusted. Camden says, that most of the celebrated races in the kingdom were called Bell Courses—hence originated the adage, "He bears the bell." In this reign, the value of English horses began to be duly appreciated, and many were purchased and exported to France. Thus, with all the pedantry of this Scottish Solomon, it is evident he was a noted admirer of all that appertains to the horse; and it is easy to imagine him invested in his sporting garb of forest-green, with a feather in his cap, and a horn at his side, contriving, in the most advanced state of age and imbecility, when unable even to sit on horseback without assistance, to follow the chase, although unable to keep his seat in the saddle without being laced, or tied up in it.

Sir Simon D'Ewes, in his Journal, speaks of "a horse-race, near Linton, in Cambridge-shire, in the reign of James I., at which town most of the company slept on the night of the race.

Gatherly, in Yorkshire; Croydon, in Surrey; and Theobald's, on Enfield Chase, when the king was resident, were the spots where races were run. The Arabian, for which James paid five hundred pounds, and which was ridiculed by the Duke of Newcastle, was of a bay colour, a little horse, and no rarity for shape. He was trained, but disgraced his country by being beaten in England by every horse that ran against him.

Butcher, in his Survey of Stamford, informs us, that a concourse of noblemen and gentlemen met every Thursday in March, together in the vicinity of that town, in mirth, peace, and amity, for the exercise of their swift-running horses. The prize they ran for was a silver-gilt cup with a cover, of seven or eight pounds, provided by the alderman for the time being. This sum was raised out of the interest of a stock formerly made by the neighbouring nobility and gentry, the well-wishers to the town.

Races were held at Newmarket, in the latter end of the reign of Charles I., although the Round Course was not made till 1666. In this king's reign, races were also run in Hyde Park, as appears from a comedy called the Merry Beggar, or Jovial Crew, 1641. "Shall we make a fling to London, and see how the spring appears there, in Spring-Garden and in Hyde Park, to see the races, horses and foot?"

At this epoch, however, the country was distracted by scenes which came too closely home to the bosom of every man to allow attention to be paid to subjects which can alone be prosecuted with effect in periods of tranquility.

Burton, in his Anatomy of Melancholy, mentions horse-racing as the disport of great men,
and good in itself, though many gentlemen, by such means, gallop out of their fortunes.

On the restoration of Charles II., the great patron of the turf, this sport, so congenial to the habits and manners of a free people, revived. The glory of Newmarket, long obscured, first by the violent spirit of contending factions, and next by the puritanical sentiments which pervaded the English mind during the Cromwellian era, again shone in meridian splendour. The palace, erected by James I., and which had fallen to decay during the civil wars, was rebuilt for the better accommodation of the "merry monarch," who personally attended, and not only gave public rewards, but kept and entered horses in his own name; thus giving an affable patronage to the sport, at which he seemed to be one of the happiest of the spectators. We are told by the quaint Evelyn that his majesty ran his own horses. "On the 10th October, 1671," says he, "after dinner I was on the heath, when I saw the great match run between Woodcock and Fleetfoot, belonging to the king and Mr. Eliot of the bedchamber, many thousands being spectators; a more signal race had not been run for many years."

When his majesty resided at Windsor, races were held on Datchet Mead; he also occasionally visited other places where these sports were instituted—Burford Downs, in particular, as may be inferred from the following doggerel verses, written by Matthew Thomas Baskerville, about the year 1630.

"Next, for the glory of the place,
Here has been rode many a race,
King Charles the Second I saw here,
But I've forgotten in what year;
The Duke of Monmouth here also,
Made his horse to sweat and blow;
Lovehe, Pembroke, and other gallants,
Have been venturing here their talents:
And Nicholas Bainton, on Black Stefan,
Got silver plate by labour and drudgery."

To Charles we are also indebted for the breed of our present race of running-horses. With a view to the improvement of our native stock, the Master of the Horse, by some said to have been Sir Christopher Wyvill, and by others Sir John Fenwick, was sent into the Levant to procure horses and mares for breeding. The mares thus procured, and also many of their produce, have been styled Royal Mares. Dodsworth, though foaled in England, was a natural Barb. His dam, a Barb mare, was imported at this period, and was called a royal mare. When twenty years old, and with foal, after the king's death, she was sold for forty guineas.

At this period, the prizes run for became more valuable. Instead of bells, pieces of plate were substituted, as bowls, cups, &c., usually estimated at one hundred guineas each; and upon trophies of victory, the exploits and pedigrees of the successful horses were commonly engraved, whence, perhaps, much curious information might be obtained, regarding the merits of the various victors. Plates, also, of different value were given in various parts of the country, and which were generally advertised in the London Gazette.

William III., notwithstanding the gravity of his character, frequently visited Newmarket; whilst Queen Anne kept race-horses, and entered them in her own name. Her majesty's brown horse, Star, won a plate at York, July 30, 1714, at four four-mile heats, the Friday preceding her death, which occurred on Sunday, August 1st. George I., in 1720, discontinued the Cups, as prizes to be run for, and ordered one hundred guineas in specie to be paid to the successful competitor.

As an illustration of the turf manners at about the period at which we have arrived, it is interesting to know that there was, at Newmarket, the keeper of the horses of no fewer than four of our sovereigns. This illustrious individual was Tregonwell Frampton, who kept the running animals of William III., Anne, George I., and George II.

Frampton was born in the troublesome reign of Charles I., in whose time horse-racing commenced at Newmarket, and was the owner of several running horses. Amongst these there was one matched to run against old Merlin, at Newmarket. Merlin was placed under the care of one Heseltine, a groom at Newmarket; upon whom Frampton's groom endeavoured to prevail to run the two horses a private trial at the stated weights and distance agreed for in the match, observing that, by that means they might both make their fortunes. Heseltine refused, but in such a manner as to give the other hopes of bringing him to compliance.
In the meantime, Heseltine took the opportunity of communicating, by a letter sent into Yorkshire, the proposed offer to Sir William Strickland, Bart., who was principally concerned in making the match. The baronet returned for answer that he might accept it, taking care to deceive Mr. Frampton's groom by letting Merlin carry seven pounds more weight than was agreed upon. Heseltine shortly afterwards consented to the proposal of Mr. Frampton's groom, who had secretly received instructions precisely similar to those given to Heseltine.

These *honest* grooms now prepared the horses accordingly, and ran the course agreed to in the article; when, after an excellent run, Merlin won by something more than his own length. This being communicated to each party by his secret and *faithful* groom, each flattered himself with certain success. Sir W. Strickland, very naturally, concluded that, as Merlin had proved himself superior with even seven pounds extra on his back, he would very easily win the race; while Mr. Frampton was decidedly of opinion that, as his horse had run Merlin so hard, carrying seven pounds more, he could not fail ultimately to win. In consequence, proposals were made and accepted to an enormous amount, even to an extent greater than was ever known; some gentlemen—in the secret—staking not only all their cash, but other property besides.

At length the hour arrived when this important business was to be decided. The horses started; and the race was won by Merlin by about the same distance as in the private trial. In a short time the secret became known; and, though it had originated with Mr. Frampton, it is certainly not a little singular that Sir W. Strickland should adopt the very same expedients.

Several gentlemen were completely ruined by this race; and it excited so much attention throughout the country, that the circumstance was at length noticed in parliament, and a bill passed in consequence, to restrain the rage for betting.

By this bill it was enacted, "that no sum of money, exceeding ten pounds, betted, laid, or agreed to between any party or parties, in future, shall be recoverable by law."

For a number of years Frampton was styled the father of the turf, and died on the 12th of March, 1727, aged eighty-six.

Let it always be remembered that the grand and important division of race-horses, in respect to their qualifications, is into the stout and the speedy.

By the first term is meant such as are stout of heart, cool in temper, and firm in constitution; generally not remarkable for readiness and speed, but calculated to succeed in a long race. By the second, such as are usually said that speed is their best, it is meant that they are best qualified for a short race, possessing a promptitude in the higher degrees of velocity, which must necessarily be of a relatively short duration. These are generally free, and of a warm temperament; and sometimes, but not invariably, of a weak and washy constitution.

It may be easily conceived, that the degrees of variation or approximation, in both of these respects, must be infinite, rendering it frequently no easy matter to determine positively to which class a horse belongs. As to the extremes, there are horses which have barely racing speed, their sole virtue consisting in their great powers of continuance, by which, in a four-mile race, they were wont to wear out their more speedy antagonists. On the other hand, there are such as no measures of art can enable them to get through a long course in the company of reputed running-horses. These have their distance, beyond which Nature has put it out of their power to go. Of this description were Fireaway, Masquerade, and Rocket of former days. The two first were most successful at the distance of a single mile; the last, at that of one quarter, or half a mile at most. It is not in the course of nature, that phenomena like Childers and Eclipse—to be spoken of immediately—should be often produced, uniting the extremes of both speed and stoutness, giving the go-by and the distance to all possibility of competition. The most useful racer, perhaps, is the animal that partakes in a nearly equal and considerable degree of both qualities, but with a superior turn towards speed. Such was the famous Shark, and such was the opinion of Chiffey, the jockey of the Prince of Wales, afterwards George IV.

The expression, *to make the play, or to go along*, will be easily understood, as leading
away in a race, at a pace of very considerable speed, upon a horse which is presumed to be stout and long-winded, in order to distress those antagonists which are known, or supposed to be inferior in stoutness. The object of this is, that such are fatigued and exhausted by long and sharp running, may not have it in their power to reserve their superior speed for the last push. Amongst horses of equal game, the play may be made by those which are in the best condition.

Waiting, or making a waiting race, is plainly the opposite practice of the above. Here, the rider of the speedy, weak, or judish horse, always aims to keep in the rear, and go as slowly as possible, until the last few hundred yards, when he well knows his power of speed will be turned to the best account.

Having thus briefly traced the early history of horse-racing in England, and explained some of the terms of the turf, we now come to speak of the selection made of those sires from which our racing-blood has derived its celebrity.

The English race-horse, like the game-cock and the bull-dog, are England’s peculiar productions, unequalled for high courage, stoutness of heart, and patience under suffering.

Cock-fighting is a wanton and barbarous sport, and is happily now nearly obsolete among the more cultivated classes; and whatever cruelties may happen on the race-course, in the punishment administered by some jockeys to their animals, they are at least not very apparent, if they in reality have an existence at all. That the practices of the turf have frequently been such as to degrade its character there can be no doubt; still, looking at its sport in a national and general way, the emulative spirit which is inspired by our races, is of immense importance in maintaining the character of the English horse. The term thoroughbred, as applied to the horse, both in Great Britain and Ireland, indicates him to be either a remote or immediate pure, unmixed descendant of the south-eastern courser, Arabian, Barb, Turk, Persian, Syrian, Egyptian, or of the neighbouring countries. The preference given to antiquity and purity of racing-blood has always been considered due to the produce of the Arabian and African deserts.

In the general outline of the figure, limbs, the shape of the head, and in the countenance, the modern English race-horse bears the strongest resemblance to the Arabian; but from the great care and high keep which he has through so many descents enjoyed in this country, he is of far greater height and bulk, and equally superior in point of power. Art is the handmaid and improver of nature; and, notwithstanding the boasted speed of animals in the natural state, there is no doubt of the superiority of the trained courser. Thus the British race-horse, even at an equality of size and power to carry weight, is far swifter and stouter in turf phraseology, and more lasting than the natural courser of the desert of the oldest pedigree. Such is the universal experience from trials in this country, and such would, in all probability, be the result, were the rival horses taken young, and trained and tried upon an equi-distant and neutral soil. This opinion may not altogether coincide with the sentiments of those who have been accustomed to read and believe in such narratives as recount, without investigation, the speed and extent of the journeys performed in a given time by Arabian horses. A little aid, however, may be given to the judgment of these gentlemen, by recalling to their minds, that there are no mile-posts in the desert; no clocks or watches wherewith to measure time; no clerks of the course to start the horses, or judges to drop the flag at the ending-post; and that the jockey himself is often the only spectator. He is likewise often the only waiter of his horse’s performances; whilst in all the Eastern writings, ancient or modern, exaggeration is the predominant characteristic.

In the early periods of the turf, recourse must have been had to foreign horses for racers, and also to the bastard breeds, as they were then styled, or mixtures between foreigners and the lightest native breed of the country. Spanish jennets, the descendants of Barbars, were trained; in short, any well-shaped nag with good action in the gallop, was deemed a racer.

The idea of thorough-bred and its peculiar qualities, had not then taken place; but was, afterwards, gradually and experimentally developed. The mild climate and granaceous soil of this country, always congenial to the nature of the horse, were found highly to improve, in size and power, the progeny of
such horses as were brought from the south. Hence, assisted by the systematic care of our turf-breeders, the British race-horse has been brought to the state of beauty, symmetry, and perfection in which we now behold him, and that superiority which all the world acknowledges and admires.

It is now upwards of one hundred years since, in this country, the greatest attention has been paid to pedigree, and to preserving the racing-breed pure and unmixed. Accidental mixtures there certainly have been, for such are upon record; but they have been comparatively few—mere drops of common, in the grand stream of pure and high racing-blood. Such crosses have been occasionally apparent perhaps for several generations, in the form and qualities of the produce; but they have been obliterated by time, and are not discoverable in the remote descents. Within this period, the phenomenon has now and then appeared of a horse not thorough-bred, such as in the cases of Sampson and Bay Malton proving winning—even capital racers. But such exceptions will not induce experienced sportsmen to infringe the general rule, of breeding from, or training horses for the course, which are not thorough-bred. The same rule holds, however anomalous it may seem, with respect to foreign horses of the purest blood, from which our thorough-breed is derived. None of them—and the experiment has often been repeated—whatever their age, size, or condition, have been found capable of contending on the course, from a race of one hundred yards to one of a hundred miles, with their relatives and brethren in blood—the race-horses of this country.

The ill-success of the Arabian purchased by King James I., and already alluded to, brought the studs of the desert into such disrepute, that we read of but few of them in the scanty annals of the turf, until the reign of Queen Anne, the last of the Stuarts who has occupied the British throne.

THE DARLEY ARABIAN.

Early in the reign of Anne, the famous Darley Arabian was imported. He was sent from Aleppo by Mr. Darley, a merchant, who had settled there, and who had procured him, through his connections, from the Arabian deserts. He is one of those few horses, on the purity of the blood of which we can have a certain reliance. The form of this animal is said to have exhibited every point desirable in a turf horse. The general characteristics of the racer are the Arabian head, the curving and tapering neck, the slanting, lengthened shoulders, the fully-developed muscular quarters, the bending hinder legs, the flat limbs, somewhat short downward from the knee, and the long and springing pastern. The Darley Arabian had these excellences, and was the sire of that wonderful racer, Flying Childers. If a judgment might be formed as to the original country of the horse, from the performances of the descendants of this animal, then the desert must have been the native soil of the general courses; but as we have already given our opinions upon this point, it need not again be touched upon here.

The great success of Mr. Darley with his imported stranger, turned the current of fashionable opinion, among English sportsmen, so much in favour of the horses of Arabia, that it became a common inducement to style all horses brought from the Levant, Arabs, whether or not they might have been really such, or Persians, Syrians, Egyptians, Turks, or Barb. This has occasioned much confusion and uncertainty; but it has been experienced, that the horses of all these countries are, in certain degrees, endowed with the properties of the race-horse, and the blood of our English thorough-bred horse is derived from a mixture of all those, although doubtless that of the Arabian and Barb predominates.

THE GODOLPHIN ARABIAN.

The Godolphin was imported into this country about five-and-twenty years after the Darley Arabian. Both of these horses were the most celebrated and valuable for their blood and high form, which have yet appeared. There are sufficient reasons, however, for the supposition that Lord Godolphin's horse was in reality a Barb.

The portrait of the Godolphin Arabian, by the artist Stubbs, gave rise to some unfavourable criticisms by his brethren of the pencil, in respect to the elevation of this horse's crest, which was said to be excessive, indeed totally out of nature. It was therefore asserted
that the painter had drawn on his imagination, in order to adorn a horse with such a lofty and swelling forehand. But, be this as it may, the Godolphin Arabian has been of the greatest importance in the improvement of the breed of the racing stud. At the present day, we have artists who seize with avidity the occasion of taking the portraits of celebrated horses, and it is not to be expected that any doubt of a likeness will take place in future, however great may be the winning horse of his time.

The fate of the Godolphin Arabian seems to have been as chequered as that of many other public characters; and he was as much indebted to accident for the development of his powers, as some of the higher breeds of the "lords of the Creation" have been. So little was he valued in France, that he was actually employed in the drudgery of drawing a cart in the streets of Paris. What an ignoble occupation for the blood of an Arab! A Mr. Coke brought him to England, and gave him to Williams, master of the St. James's Coffee-house, who made a present of him to the Earl of Godolphin. Though now elevated from the cart in the streets of Paris, to the stud of a British nobleman—whose name the Arabian afterwards bore—his merit was still unappreciated to the fulness of its extent; and it was not until he had produced a colt foal, the famous Lath, the most elegant and beautiful as well as the best racer of his time, that he was now treated "according to his deserts." He then became, even in a higher degree than the Darley, one of the progenitors of our thorough-bred horses.

The Godolphin was fifteen hands in height, of great substance, of the truest conformation for strength and action, bearing every indication of a real courser. His colour was entire brown bay, with mottles on the buttocks and crest, excepting a small streak of white upon the hinder heels. He was imported into France from some capital or royal stud in Barbary, whence it was suspected he was stolen. He was foaled in 1724 and died in 1753.

THE WELLESLEY ARABIAN.

We introduce this horse because he has been considered, although erroneously, the finest specimen of a superior Arabian. He bore a considerable resemblance to the larger war-horse of Europe, possessing the delicate skin, and various other attributes of the south-eastern courser. But it is with reason supposed that he was the produce rather of some country bordering on the land of deserts, than in Arabia itself. In England, the Arabian or Barbary horse, in process of time, acquires an increase of size, and fulness of form, together with a considerable expansion of the hoofs. This is, no doubt, the effect of lower and more moist grounds, and more succulent food than can be found in the deserts. There the dryness and purity of the air and soil compress the animal body, impart a superior firmness and elasticity to the tendinous and fibrous system, allowing greater powers in a smaller compass of substance, and exalting the tone and vigour of the animal spirits. For these reasons horses are chosen from the deserts for their fleetness and courage, and from the mountainous regions for coursers. A few of the offspring of the Wellesley Arabian were trained, but not with sufficient success to raise his reputation as a covering animal. This is the last Arabian, or foreign horse trained from, in this country.

THE DEVONSHIRE, OR FLYING CHILDERS.

Childers, a bay horse, somewhat upwards of fifteen hands in height, was foaled in 1715, and was the property of Leonard Childers, Esq., of Carr House, near Doncaster, and sold, when young, to the Duke of Devonshire. He was the immediate descendent of the Darley Arabian; and his history, as a racer, is so well known, and has been so often repeated, that a few items of it will here suffice. It is said that he was first used as a hunter, and that in the field, both his high qualities and his headstrong, if not vicious disposition, were discovered. He was, however, void of any taint of restiveness. It is probable that, like Eclipse, he did not start on the course until five, perhaps not until six years old, when he beat all the horses of his time, at whatever distance. He was never tried in running a single mile; but since his time, the measured and attested performances of far inferior horses, leave not the shadow of a doubt of his ability to run a mile within one minute of time! A horse called Firetail, ran, in 1772, a mile in
sixty-four seconds. Carrying nine stone two pounds, he ran over the Round Course, at Newmarket, three miles, six furlongs, ninety-three yards, in six minutes and forty seconds, when he was judged to move eighty-two feet and a-half in one second of time. He likewise ran over the Beacon Course, four miles, one furlong, one hundred and thirty-eight yards, in seven minutes, thirty seconds, covering at every bound a space of twenty-five feet. He made a spring or leap of ten yards, upon level ground, with his rider on his back. These are a few of the celebrated feats of this famous horse, which, in 1741, died at the age of twenty-six.

**BLEEDING CHILDERS.**

Bleeding Childers, so called from his frequent bleedings at the nose, afterwards called Young Childers, and finally Bartlett's Childers, was full brother to Flying Childers. He was never trained; but proved a very superior stallion. The Hampton-court Childers, sire of Blacklegs, was son of the Devonshire Childers. There were, in all, six nearly contemporary racers and stallions of the name of Childers.

**KING HEROD.**

King Herod, descended by his dam from Flying Childers, was of the highest reputation as a racer; whilst, as a stallion, he stands among the first, if he be not really the very first, in modern times. He has been ranked higher than Eclipse in this respect; some of his stock having been not only among the most speedy, but the generality of them the stoutest and best constituted horses the turf, at any period, has produced. He was a bay, about fifteen hands three inches high, and foaled in 1758. He was got by Tartar, out of Cypron. There was another Tartar, got by Blaze; but Tartar, the sire of King Herod, was got by Croft's Partner—one of our most famous racers—out of Meliora, by Fox. Partner, grandsire of King Herod, was foaled in 1718. He was a chestnut horse, of great power, exquisite symmetry and beauty, and immediately succeeded Flying Childers, as the best animal at Newmarket, giving weight to, and beating horses of the highest repute, over the course. He was got by Jig—no pedigree of dam—son of the famous Byerley Turk, and shows a pedigree through a list of highly reputed progenitors, concluding with the well-known Old Vintner Mare. Partner died in 1747, aged twenty-nine. Cyron, King Herod's dam, was got by Blaze, a son of Flying Childers, out of Sir William St. Quintin's Selina, got by the Bethell Arabian, and boasting in her lineage, Champion, the Darley Arabian, and Old Merlin. King Herod's pedigree consists of the oldest and purest blood.

Whilst speaking of the pedigrees of horses, however, we may here observe, with Admiral Rous, that "nothing can be more unsatisfactory than the pedigrees of English race-horses up to 1750. Although Charles II. and Queen Anne kept magnificent studs, and agents were employed by the masters of the horse of several successive sovereigns, to purchase valuable Eastern blood, no records were kept, and we are in ignorance respecting the breed of the royal mares. It was not until 1791, that Mr. Weatherly, the keeper of the Match-Book, obtained a list of pedigrees collected by a private gentleman. A register was then kept, and the *Stud-Book* was published in 1808. Since that time a regular account has been kept of the produce of thorough-bred stock; but many proprietors of brood mares will not take the trouble to register their foals. . . . The original intention of the compiler of the *Stud-Book*, was to register all the winners in the official *Racing Calendar*; but a cloud hangs over the book, threatening a formidable race of rivals to dispute the value of the orthodoxy of the pure breed. . . . Although it is an axiom in breeding animals, from man downwards, that a fresh cross of good blood is most desirable, we have failed to have made any improvement in our race-horses by importation of any Eastern blood during the present century, simply owing to the extraordinary superiority which our horses have obtained in point of strength, size, and speed, over the original stock." Herod, like Childers and Eclipse, did not start upon the course until five years old. He never ran anywhere but at Newmarket, Ascot Heath, and York, and always over the course, or four miles; stoutness or game, and ability to carry weight, being his play. He ran five times for a thousand guineas each race, and won three of them. The last race
he won was against Aschem—a curious one, from the circumstance of two aged horses carrying feathers, five stone seven, and six stone. He won several matches for five hundred guineas, and a sweepstake of three hundred guineas, nine subscribers.

The fame of this racer as a stallion, in the Turf Register, is truly splendid. In nineteen years—namely, from 1771 to 1789—four hundred and ninety-seven of his sons and daughters won for their proprietors, in plates, matches, and sweepstakes, the sum of £201,505 9s., exclusive of some thousands won between 1774 and 1786. He was the sire of the celebrated Highflyer, bred by Sir Charles Bunbury, which was never beaten. Herod also got Woodpecker, Bourdeaux, Anvil, Hammer, Sting, Adamant, Plunder, Quicksand, Rantipole, Whipeord, and many others, among which were the speediest horses of their day. Tuberose, Guildford, and Latona, were rare examples of the family stoutness, and Laburnum was an excellent and useful racer. The list of brood mares got by Herod is very large.

King Herod first covered the property of Sir John Moore, Bart., at ten guineas. In 1774 his price rose to twenty-five, at which it remained till his death, in 1783, in the twenty-second year of his age.

This noble animal was so shamefully neglected in his latter days, and his body so encrusted with dung and filth, that, it is said, the immediate cause of his death was a mortification in his sheath. Many much later instances are known of covering stallions neglected in a similar way. George IV., when Prince of Wales, formerly allowed the breeders in the vicinity of his residence in Hants, the use of a well-bred stallion gratis, excepting the groom’s fee of a crown: the consequence of which was the exhaustion of the animal. So many mares were sent, that it was impossible for nature to support the continued demand; and the result was the most wretched, puny, spindle-shanked produce to be imagined.

MARSK.

This horse was foaled in 1750, and so named from the place where he was bred, being the property of John Hutton, Esq., of Marsk, Yorkshire, who afterwards disposed of him to his royal highness, William, Duke of Cumberland. He was got by Squire, son of Bartlett’s Childers, out of the Ruby mare. She was from a daughter of Bay Bolton and Hutton’s Black Legs—Fox Cub—Coneyskins—Hutton’s Grey Barb—a daughter of the Byerley Turk, from a Bustler mare. This is one of our highest bred pedigrees, going back to the reign of Charles I. In the year 1750, the duke made an exchange of a chestnut Arabian with Mr. Hutton, for the colt, which his royal highness afterwards named Marsk.

In Mr. Hutton’s Stud-Book, printed by Weatherby in 1801, appear the following extracts:

“In the year 1750, his royal highness the Duke of Cumberland, gave me—John Hutton—a chestnut Arabian in exchange for a brown colt, got by Squire, bred from the Ruby mare; and which his royal highness afterwards called Marsk.

“My Black Legs was got by the Mulco Bay Turk; his dame by Coneyskins; his grand-dam was the old Club-foot mare, got by Mr. Weekes’s Hautboy.”

“The above are true copies from Mr. Hutton’s Stud-Book.

E. GELDART.

MARSK, October, 1801.

The history of Marsk, like the Godolphin Arabian, was highly eventful, and distinguished by alternate depression and elevation.

He was a capital racer, and beat Brilliant; but he was an uncertain horse. Being in low estimation as a stallion in the duke’s stud, he was sold at his royal highness’s sale, at Tattersall’s, to a farmer for a trifling sum; and in 1766, as will be observed in the history of Eclipse, covered country mares and foisters, at half-a-guinea. When Mr. Wildman, the purchaser of Eclipse, found his intelligence respecting that colt correct, he thought it advisable to get into his possession his sire, and bought Marsk of the farmer for twenty pounds, who professed himself happy at being well rid of a bad bargain.

This animal has been styled the “prince of horses.”

It is sufficient to say that, besides so many other racers of high reputation, he was the sire of Eclipse, Shark, Pretender, Honest Kitt, Masquerade, Leviathan, Salopian, and Pontiac.

Shark won sixteen thousand and fifty-seven
guineas, in matches, sweepstakes, and plates; beating the best horses of his day, at their own play, whether for speed or stoutness.

Marsk seems to have had the caprices of fortune imparted to him as an inheritance from his sire. Squirt, after running with great repute, became a stallion in Sir Harry Harpier's stud, who esteeming him of no worth, ordered him to be shot. As the huntsman was leading him out of the dog-kennel, he was begged off by the stud-groom; and this poor, despised, death-doomed animal afterwards got Marsk, the sire of an immense number of excellent horses, whose united winnings are not now to be calculated. The immediate progeny of Marsk, however, realised to their owners upwards of seventy thousand pounds.

Marsk died in July, 1779, in his twenty-ninth year.

ECLIPSE.

Eclipse, fully master of sixteen stone, was bred by William, Duke of Cumberland, of Culloden memory, and foaled during the great eclipse in 1764, whence the name given him by the royal duke. He was got by Marsk, a grandson, through Squirt, of Bartlott's Childers— to be noticed further on—out of Spilletta. Spilletta was got by Regulus, son of the Godolphin Arabian, out of Mother Western, which mare was got by a son of Snake, full brother to William's Squirrel, her dam by Old Montague, grandam by Hautboy, out of a daughter of Brimmer—her pedigree not preserved. Such is the carefully chronicled evidence of the purity of our race-horses from Oriental blood.

The proportions of this animal, as given by Mr. St. Bell, the founder of the Veterinary College in St. Pancras, are as follows:

The length of the head of the horse is supposed to be divided into twenty-two equal parts, which are the common measure for every part of the body.
Three heads and thirteen parts will give the height of the horse from the foretop to the ground.
Three heads, from the withers to the ground.
Three heads, from the rump to the ground.
Three heads and three parts, the whole length of the body, from the most prominent part of the chest to the extremity of the buttocks.
Two heads and twenty parts, the height of the body, through the middle of the centre of gravity.

Two heads and seven parts, the height of the highest part of the chest from the ground.
Two heads and five parts, the height of the perpendicular line which falls from the articulation of the arm with the shoulder directly to the hoof.
One head and twenty parts, the height of the perpendicular line which falls from the top of the fore-leg, dividing equally all its parts to the fetlock.
One head and nineteen parts, the height of the perpendicular line from the elbow to the ground.
One head and nineteen parts, the distance from the top of the withers to the stifle. The same measure also gives the distance from the top of the rump to the elbow.
One-and-a-half head, the length of the neck from the withers to the top of the head. The same measure also gives the length of the neck from the top of the head to its insertion into the chest.
One head, the width of the neck at its union with the chest.

Twelve parts of a head, the width of the neck in its narrowest part.
The same measure gives the breadth of the head taken below the eyes.

One head and four parts, the thickness of the body from the middle of the back to the middle of the belly.
The same measure gives the breadth of the body.

Also the rump from its summit to the extremity of the buttocks.

Also the distance from the root of the tail to the stifle.

Also the length from the stifle to the hock.

Also the height from the extremity of the hoof to the hock.

Twenty parts of a head, the distance from the extremity of the buttocks to the stifle.

Also the breadth of the rump or croup.

Ten parts of a head, the breadth of the fore-legs from their anterior part to the elbow.

Ten parts of a head, the breadth of one of the hind-legs taken beneath the fold of the buttocks.

Eight parts of a head, the breadth of the ham taken from the bend.

Also the breadth of the head above the nostrils.

Seven parts of a head, the distance of the eyes from one great angle to the other.

Also the distance between the fore-legs.

Five parts of a head, the thickness of the knees.

Also the breadth of the fore-legs above the knees.

Also the thickness of the hams.

Four parts of a head, the breadth of the pastern, or fetlock joint.

Also the thickness of the coronet.

Four-and-a-half parts of the head, the breadth of the coronet.

Three parts of a head, the thickness of the legs at their narrowest part.
Also the breadth of the hinder-legs, or shanks.
Two-and-three-quarter parts of a head, the thickness of the hind pasterns.
Also the breadth of the shanks of the fore-legs.
Two-and-a-quarter parts of a head, the thickness of the fore pasterns.
Also the breadth of the hind pasterns.
One-and-three-quarter parts of a head, the thickness of the fore and hind shanks.

Such are the proportions of this famous horse, which in form, constitution, and action, seemed to comprehend every excellence for the course. When a yearling, he was purchased by Mr. Wildman, a sporting sheep salesman of Smithfield, for seventy-five guineas, on the decease of the Duke of Cumberland, at the sale by auction of his royal highness’s stud. Marsk, the reputed sire of Eclipse, subsequently, on the New Forest, covered country and forest mares at half-a-guinea each. But, after the transcendent qualities of Eclipse were established, the same Marsk covered at one hundred guineas a mare, and was advertised in succeeding seasons by Lord Abingdon, his proprietor, at two hundred or three hundred guineas a mare. Wildman had a friend in the old duke’s stud, from whom he obtained a hint of the superior form of the Eclipse colt; but making the journey in haste, he did not arrive until the sale had commenced, and his object had been already knocked down at seventy guineas. Appealing instantly to his watch, which he knew to be a correct time-piece, he found the hour had not arrived by several minutes at which the commencement of the sale had been publicly advertised, and thence firmly insisted there had been no lawful sale, and that the lots knocked down should be put up again. The knight of the hammer, well aware of the resolution and pecuniary weight of Mr. Wildman, very prudently offered him the chance of any lot he should choose. Eclipse was put up again, and Wildman purchased the yearling at an advance of five guineas.

Immediately previous to Eclipse running for the King’s Plate, at Winchester, in 1769, Colonel O’Kelly purchased the half share of him for six hundred and fifty guineas; and, afterwards, the remaining share for eleven hundred guineas.

Eclipse, for what reason has never been published, did not appear upon the turf until he was full five years old, when he was entered at Epsom for the Maiden Plate of fifty pounds. There can be no doubt that his trials at Epsom had been watched, as the odds at starting were four to one in his favour.

O’Kelly was, doubtless, well aware of the qualities of his maiden horse, by the large sums he then betted at such considerable odds. In running the second winning-heat, the whole five horses were close together, at the three-mile post, when some of the jockeys used their whips. Eclipse was quietly jogging on at a moderate rate; when, alarmed by the crack of the whips, he bounded away; and, notwithstanding his jockey held him back with all his strength, not one of his competitors could save his distance.

In running over the course at York, in the following year, for the Subscription Purse against Tortoise and Bellario, two first-rate racers, but aged, Eclipse took the lead; and the jockey, being unable to hold him, he was more than a distance before his competitors at the end of two miles, and won the race with the utmost ease. At starting, bets of twenty, and in running, one hundred pounds to a guinea were offered on Eclipse. On a certain race, O’Kelly bet five and six to four that he posted the horses—that is to say, named, before starting, the order in which they would come in. When called on to declare, he named—“Eclipse first, the rest in no place;” and won his money—Eclipse distanced all the rest. Being distanced, they were, consequently, in a sporting sense, in no place.

Eleven King’s plates, the weight carried for all of them being twelve stone (one excepted, ten stone), were won by Eclipse. In twentythree years, three hundred and forty-four winners, the true progeny of this matchless courser, produced, to their owners, the sum of £15,071 12s., various prizes not included.

About the year 1779, a noble duke, or some sporting member of his family, demanded of O’Kelly how much he would take for Eclipse? The reply was—“By the Mass, my lord, and it is not all Bedford Level that would purchase him.” We state, on the authority of the keeper of a sporting coffee-house, frequented by Colonel O’Kelly, that this gentleman asked the sum of twenty-five thousand pounds down,
an annuity of five hundred pounds on his own life, and the annual privilege of sending six mares to the horse, as the price for Eclipse. O'Kelly affirmed, that he had acquired upwards of twenty-five thousand pounds by Eclipse.

Of the speed of this animal too much cannot be said; but we have no rule by which to judge of his stoutness or game, since no cotemporary racer was able to run for a moment by his side, far less able to try his power of continuance. If it be said, that he contended with middling horses only, the two or three capital ones that met him, having passed their prime, it must be remembered that those horses he distanced, and probably could have doubly distanced. The jockeys rarely if ever held him. The horse was always allowed to run according to his own will, yet he never swerved from his course, and, at the ending post, pulled up easily enough. O'Kelly, his proprietor, was yet apprehensive that he might, at some time, break away; and when the horse run over the course at York, with twelve stone, which he was judged to have performed in eight minutes, a number of men were placed at the ending post, with the view of stopping him, in case the jockey should be unable to pull him up—a precaution which proved entirely needless. He never felt the whip or spur on any occasion.

The only cotemporary which was supposed to have any pretensions to contend with Eclipse, was Mr. Shaftoe's famous Goldfinder, by Snap, a beautiful and long-reached brown animal. He was never beaten, and would have met Eclipse, to run for the King's plates, but he broke down previously.

The characteristics of the Eclipse racers were speed and size; and many of them bent their knees, and took up their feet in the gallop, with extraordinary activity. If few of them were stout, still fewer of them wanted steadiness; a restive or swerving horse being seldom found of that blood.

The eye of Turf science is directed, in the portrait of Eclipse, to the curve in the setting-on of his head, to his short fore-quarter, to the slant, extent, and substance of his shoulder, the length of his waist, and the breadth of his loins; to the extent of his quarters, and the length and substance of his thighs and fore-arms. Although a strong, he was a thick-winded horse; and, in a sweat or under severe exercise, was heard to blow at a considerable distance.

Eclipse first covered at fifty guineas; afterwards at twenty, being stinted to fifty mares, exclusive of those of his owner; ultimately at thirty guineas. In his progeny are ranked no fewer than three hundred and thirty-four winners.

In 1788, his feet having been neglected, he was removed from Epsom to Cannons, in a four-wheeled carriage, drawn by two horses, his groom being an inside passenger with him. The old racer and his attendant took their necessary refreshments on the road together. This splendid quadruped died at Cannons in the following year, on February 28th, aged twenty-five years; and, according to the precedent of the Godolphin Arabian, cakes and ale were given at his funeral. His heart weighed thirteen pounds; and his skull was extremely large. It was shown to Dr. Spurzheim, one of the celebrated founders of phrenology, who thus remarked upon the powers of the animal, judging from the craniological development:

"The leading characteristics of Eclipse," he said, "were a remarkably large brain, not only in proportion to the size of the animal, but to horses in general; indicating great and high courage, unusual sagacity, but deficient in meekness, or rather possessed of a vicious temper." He further remarked that considerable difficulty must have been experienced in rendering such an animal subservient to his rider; but that, when subdued, he could be best governed by gentle treatment, and would prove docile under proper authority. The professor's observations have been esteemed remarkably correct.

There was an uncertainty in Eclipse's pedigree, arising from the circumstance of his dam having been barren in the previous year, and, in the next, covered by both Shakespeare and Marsk, and not coming to Shakespeare's, but to Marsk's time. A strong resemblance, however, existed in Eclipse, to the progeny of Shakespeare, in the particulars of colour, temper, and certain peculiarities of form.

Mr. John Lawrence, who was well acquainted with this animal, says—"Never, to the eye of a sportsman, was there a truer-formed galloper in every part; and his countenance and figure, as he stood in his box, notwithstanding his
great size, suggested the idea of the wild horse of the desert. His resolute and choleric temper was well known; and although he held a very familiar and dumb converse with us over the bar, we did not deem it prudent to trust ourselves alone with him in his apartment. He was nevertheless very kind and friendly with his groom.”

In observing on the general character of the running of this animal, we cannot but remark that it was impossible to make a tool of him, even had it been desired, or had his owner intended to do so. He was no horse that could win a race to-day, and be beaten on the morrow by another horse of inferior powers. He seemed to have made up his mind to be always a winner, and resisted all the attempts of his jockeys to force him to accommodate his pace to that of his opponents. He took the lead, and gallantly maintained it, in spite of all opposition. Were there more horses of the temper of Eclipse, there would be less ness practised on the race-course of the present day.

In closing the history of this animal, we must quote a few more extended observations of Mr. St. Bell, on some of his proportions. The Essay of that gentleman is replete with sound and practical information, expressed in clear and intelligible language; and is worthy of the perusal of all those that take an interest in such things as have a tendency to enhance the strength, beauty, speed, and splendour of the horse.

“The difference which results from peculiar conformation,” says Mr. St. Bell, “militates, in some respects, against the rules laid down in the geometrical table in use in the veterinary schools on the continent of Europe, and proves that no common standard of measurement can apply generally to different species. As each species, and even each individual, has its own peculiar beauty, we cannot pretend to establish any general rule of beauty for the horse. Were a man to collect the various beauties of individuals, it might, indeed, serve as a model for the painter, or the statuary, but would be of no use to direct him in the choice of a horse. Eclipse was never esteemed handsome; but in making, he was nearly perfect, and speedy in proportion. *

“We may propose that the legs of Eclipse, in their flexion in the gallop, described each a circle of three hundred and sixty degrees; and, consequently, the extent of the action of each leg was the same in extension. To this may be added the force of action, without which a horse cannot even walk. This muscular, and merely mechanical force, can only be computed by experiment; and well organised as Eclipse was, as to his muscles and the length and direction of his legs, we may venture to assert that, free of all weight, and galloping at full speed, he could cover an extent of twenty-five feet at each complete action of the gallop; that he could repeat this twice and one-third in each second; consequently that, doing his utmost, he could run nearly four miles in six minutes and two seconds.

“The excellence of the make of Eclipse may fairly be inferred from his superior speed; for this speed could result only from a harmonious combination in the organs of progression. Let us now suppose these same organs defective in their proportion, and inquire what would be the consequence.

“The GrouP AND Rump.—An examination of the bones of the ilium, confirmed me in my opinion, held during life, that the croup in Eclipse was disproportionately large. The extent of the os pubis and ischium caused him to go too wide behind. His hind-feet, instead of being parallel with his fore-feet, stood outward. This defect, which caused a wavering in the croup, in his gallop, together with other small defects, was overruled by his great muscular powers. A much greater fault in a racer is, when the croup is too narrow, and the muscles, which communicate with the loins and extremities, thin, and, consequently, weak.

“The Shoulder and Arm.—In Eclipse, the shoulder was too much loaded; but if too spare, the muscles will be weak, and the motions of the shoulder confined. The proportion of the arm is commonly determined by that of the shoulder-blade. These two parts, forming together the sides of an angle, more or less open, give to the muscles which move them, a quicker or less power, in proportion as this motion is made further from, or nearer to, the axis of the motion.

“The Hind Leg—The Thigh.—Eclipse was remarkable for length in his hinder parts.
The thigh, with the os-illium, formed a considerable angle, whence followed a great extent of motion. The length of the tibia gave beautiful proportion to the leg; and the hock, from its size, and perfect make, must have produced the greatest possible degree of extension. The leg, pastern, coronet, and foot, fully corresponded."

In order to see at a glance the dimensions of Eclipse, we make the following extract from the same authority:

The skeleton of this splendid animal, after passing through various hands, is now kept in the New Veterinary College, at Edinburgh, for which it was purchased for one hundred guineas from Mr. Bracy Clark, by Professor Gamgee.

**BAY MALTON.**

This horse was the property of the Marquis of Rockingham, and ran the four mile course at York, in seven minutes and forty-three seconds, a feat which had never been accomplished before in so short a time, by seven seconds. He combined great speed with considerable stoutness.

One of the severest plate-races on record, was run at Carlisle, in 1761, and in which there were no fewer than six heats, and two of them were dead heats, each of which was contested by the winner of the plate. The winning horse, therefore, ran twenty-four miles, and yet did not break down.

In 1768, at Salisbury, and over a four mile course, there were four heats between two horses—the Duke of Grafton’s Havannah, and Mr. Wildman’s Pam. Yet there was no breaking down.

One or two more instances of the combined speed and stoutness of former racers, are worthy of being placed on record.

In October 1741, at the Curragh meeting, in Ireland, Mr. Wilde engaged to ride one hundred and twenty-seven miles in nine hours. He performed it in six hours and twenty-one minutes, and employed ten horses. Allowing, therefore, for mounting and dismounting, and a moment for refreshment, he rode for six hours, at the rate of twenty miles an hour.

In 1745, Mr. Thornhill exceeded this, for he rode from Stilton to London, two hundred and thirteen miles, in eleven hours and thirty-four minutes; which is, after allowing the least possible time for changing horses, twenty miles an hour for eleven hours, and on the uneven ground of the turnpike-road.

In 1762, Mr. Shaftoe, with ten horses, and five of them ridden twice, accomplished fifty miles and a quarter, in one hour and forty-nine minutes. In 1763, this gentleman won a more extraordinary match. He was to procure a person to ride one hundred miles a day, on any one horse each day, for twenty-nine days together, and to have any number of horses not exceeding twenty-nine. He accomplished it on fourteen; and on one day he rode one hundred and sixty miles, on account of the tiring of his first horse.

Mr. Hull’s Quibbler, however, affords the most extraordinary instance on record, of the stoutness as well as speed of the race-horse. In December, 1786, he ran twenty-three miles round the flat of Newmarket, in fifty-seven minutes and ten seconds.

**POT-S-OS.**

This was one of the numerous progeny of Eclipse, and holds a foremost place in the racing ranks. He was a chestnut foaled in 1773, his dam being Sports-mistress. He was bred by the Earl of Abingdon. At the Newmarket first spring of 1788, his proprietor had intimated his intention of disposing of some of his horses, whilst Pot-S-os was engaged in a sweepstake of one hundred guineas each, eight
subscribers. As the horses were starting, Lord Grosvenor asked the Earl of Abingdon the price of Pot-S-ros. "Fifteen hundred guineas," was the reply. "With the chance of the race?" "Oh, certainly!" The transaction was closed; and, in a few minutes after, Pot-S-ros and the subscriptions were Lord Grosvenor's. This horse died at Herne Park, Newmarket, in 1800, aged twenty-seven. His progeny hold a place in our best pedigrees.

HIGHFLYER.
This is one of the most celebrated racers on record. He was never beaten, and never paid forfeit. He was a bay horse, descended from King Herod, and foaled in 1774. Sir Charles Bunbury bred and sold him to Viscount Bolingbroke, and he afterwards because the property of Mr. Richard Tattersall. He flourished between the years 1776-80; witnessed the establishment of the St. Leger, the Derby, and the Oaks; and when he was christened, the statesman, Charles James Fox, was present at a festive meeting. Although he never started after five years old, his winnings amounted to upwards of nine thousand three hundred pounds, and his immediate descendants netted about one hundred and seventy thousand, four hundred pounds. He died at "Highflyer" Hall, Cambridgeshire, an elegant villa near Ely, the property of Mr. Tattersall, October 18th, 1793 aged nineteen years.

ESCAPE.
On the 20th of October, 1791, Chifney, the jockey of the Prince of Wales, afterwards George IV., rode the prince's famous horse Escape, by Highflyer, in a sweepstakes, from the Ditch-In, a distance of about two miles, against Skylark, Pipulator, and Coriander; and the last won. On the following day Chifney rode Escape against the same horses over the Beacon course, a distance of four miles, and won. The betting on this race was four and five to one against Escape. Public rumour stated that the prince had gained a vast sum; but he gave a flat denial to his having won above four hundred pounds on the race; and having believed, as it was generally rumoured, that Chifney had ridden boot, a public investigation took place, and the whole resulted in the final retirement of his royal highness from the turf. Escape beat the best horses in England, over the course of four miles, and was himself beaten on the same course, by middling horses. He beat Nimble, one of the speediest horses of his day, across the Flat, a distance of a mile and a quarter; and was beaten on the same course, in a private trial, by Don Quixote, and Lance—horses, we believe, of inferior speed to Nimble—several lengths before half the course was ran, and very easily, and a great way at the end; yet in another trial, two miles over Epsom, he beat Baronet and Pegasus, giving the former, a horse of his own year, and a winning racer, the enormous weight of twenty pounds. Baronet nevertheless beat him, at the same weight and distance, a few days after, at Ascot.

From a detailed account of the trials and public races of Escape, he clearly appears to have been a most uncertain runner. He seems to have possessed capital speed, and even great powers of continuance, when well to run; but to have been materially affected by the very slight and very usual mistakes in training; to have been subject to have the edge of his speed totally blunted by a few degrees of overwork; and his powers, both of speed and continuance, paralysed and rendered inert, by want of due exercise, or by errors in feeding, more particularly near the time of his running. There, also, most assuredly, is a perfect analogy of nervous sensibility, of irritability, and vacillation of fibre, between the human animal and the race-horse. As men differ, so do horses; and the warm-tempered, free, unequal, and nervous Escape, ought to have had for his trainer, his manager, and his jockey, such discriminating persons as could fully appreciate his temperament and disposition. Hard-headed and indiscriminating grooms of the common type, could have no real conception of the delicacy, vigilance, and care with which such an animal required to be treated.

As the failure of this horse led to the trial of Chifney, his rider, and the retirement of the Prince of Wales from the turf, this seems the proper place to give the opinions relative to the management of a race-horse, elicited from Chifney at his trial; and, although they are the sentiments of an uneducated, yet they are those of a practical man, and, on that account, deserving a place in this
work. We may premise that Chifney entered into the service of the running stables in 1770, and was regularly trained to his vocation, under the celebrated professors Fox and Prince. Riding, he says, "he learned himself. In 1773, I could ride a horse in a better manner in a race, to beat others, than any person ever known in my time. In 1775, I could train horses for running better than any person I ever yet saw." In 1784, he lived with Lord Grosvenor, riding his lordship’s race-horses. He afterwards entered into the service of Thomas Panton, Esq., with whom he continued four years, until his engagement in the service of the prince. During his continuance with Mr. Panton, he rode most of the Duke of Bedford’s race-horses; and tells us, he was assured by Mr. Panton, that "the Duke of Bedford was always highly pleased with his riding, as he always rode to a T, as his grace told him." His grace is well known to have been very precise in his directions to his jockeys; and appears to have been so well satisfied with Chifney, that, in all probability, had not his grace then meditated a total retirement from the turf, he would have engaged him for life. Immediately on quitting the service of Mr. Panton, he was engaged by his royal highness the prince, at a salary of two hundred pounds per year.

"I have said," observes Chifney, "that horses change in their twice running. If a horse is in perfect fitness for running, he immediately becomes exhausted, little or much. He must then change in his running. A horse cannot keep his perfect fitness for running more than one race till rested. I have seen one sweat between a horse’s twice running, change him for the worse, astonishingly. It is destruction to horses to sweat them in the manner they are sweated at Newmarket, as the practice there is to sweat them once in six days—sometimes oftener; and between these days of sweating, it is usual for the horse to go out twice a day, each time having strong exercise. In these sweating-days the horses are mostly covered with cloths, two or three times doubled, and go in their sweats six miles, more or less, and, at times, go tolerably fast. Directly the horse pulls up, he is hurried into the stable, which is on the spot for that purpose. As soon as he gets in, there is often more clothes thrown upon him, in addition to those he had been sweated in. This is done to make the horse sweat the more; and he stands thus for a time panting, before he is stripped for scraping; and with being thus worked, clothed, and stoved, he is, at times, so affected, that he keeps breaking out into fresh sweat, which pour from him, when scraping, as if water had been thrown on him. Nature cannot bear this. The horses must dwindle."

"Now I think, in the first place, that the horse has been too long at this sort of work for his sinews; then the clothing and stoving him force his juices from him in such quantities, that his spirit, strength, and speed must be destroyed; and much clothing jades horses. A horse don’t meet with this destruction when he runs, for then he is likely to be lighter in his carcase, lighter in his feet, having plates on, not shoes, which are wonderfully in favour of his sinews; and he is without clothes, and not stoved, and his course in running is very seldom more than four miles; therefore, this difference between sweating and running is immense."

"When a horse pulls up from his running, he has time given him to move gently in the air, and is usually scraped out upon the turf, and by these means he perspires no more than suits his nature."

"Horses should have different brakes, against weather, to scrape in. Buildings for this, I think, would be most properly made after the horse-dealer’s rides in London; open in front, being out of the weather, and not out of the air. Places of this sort would be much the best for horses to saddle in; for saddling in close, dark stables, makes them, at times, break out with great perspiration when under that operation. Besides, in fine roomy places of this sort, there would be proper space, &c., for noblemen and gentlemen sportsmen to command a sight of the horses at saddling; and horses are less timid, when in a crowd, than they are when not in it, yet hear it."

"When a horse is first taken into work, after having had a long rest, his carcase is then large and heavy; and the practice is to put more clothes upon him, and order him to go a longer sweat. But the horse, in this stage of his training, is the less able to bear more
clothes, and go further in his sweats; for, he himself being heavy, has, with boy and clothes, at times a great weight upon his legs. Therefore, what with this pressure, and his work heating him, it makes his sinews full and weak; and thus working a little too fast, or too long, upon his sinews at one stretch, they are forced out of their places. This once done, the horse seldom stands training after.

"It is ignorant cruelty that causes a number of horses to be unskilfully lamed at Newmarket; when gentlemen not only lose the use of the animals and their money, but they are deprived of the sport they otherwise might have.

"The principal care in training horses for running, and hunters and hacks for hard riding, is, to train the legs to be able to carry the carcase. To do this they should first be used to short exercise, short gallops, short sweats, and time given between their work for their sinews to rest, or the best of legs will become destroyed.

"The legs of horses are very soon destroyed at first coming into work; but when they have had time to be well trained, scarcely any running or riding will hurt them.

"Some few, I am informed, have a way of pinching their race-horses in their meat and water. This is another certain way of perishing a horse in his spirit and strength. Where a horse is too large in his carcase, he should be well fed, as horses are, I believe, for the most part, at Newmarket; and, instead of pinching him in his water, where a horse is greedy of it, he should be watered very often, and, at all times, as much as he will drink given to him. He will then drink less, and come straight and strong in his carcase.

"The outcry is, Why are there so few good runners, or that the turf-horses degenerate? Some say they think it is from running horses too young. My opinion is, that the best running mares are trained till their running is gone from them little or much; then they are turned into the stud, exhausted of their juices. Perhaps they drop a foal in the following year, and so on, year after year, suckling one foal while breeding another. The mare thus turned into the stud, is drained of her strength; and being kept continually breeding, without she lays herself barren a year or two by her mis-standing to the horse, she will remain bereft of her strength. But the chance manner of her being allowed to lay herself fallow, gives her an opportunity of recovering her juices or strength, to enable her to breed a stronger foal, provided the horse that is put to her, is in the same proper state. As it is with the mares, so is it with the horses. They are turned out of training into the stud, drained of their nature; and the better runners they are, the more are they pressed with mares, and in such numbers as to exhaust their prolific powers.

"These are my reasons why the turf-horses degenerate in length, speed, and beauty."

Lord Coleraine was confederate on the turf with his friend, Mr. Robert Pigott, when his celebrated horse, Shark, was at his best; Mr. Pigott trusted the whole management of his stables to him. He says——

"I do not believe there ever was a better horse than Mr. Robert Pigott's Shark, excepting Eclipse, which was a very uncommon horse. I will tell you what Shark could do, by which you may give a tolerably good guess whether you have nearly the best horse of his year. Run five or six of your young colts together, one mile: if they all come in well together, you may be sure that not one of them is worthy to be kept in training, excepting you have one amongst them which is an uncommonly large-sized colt, large-limbed, and loose made. It is possible that, when he comes to his strength, and fills up, he may turn out a good horse. If you have one colt which, in the trial, runs clear away from all the rest, you may expect that he will turn out a good runner. Take him, about a fortnight after, run him with two of the others which were the two first of those beaten; for you must not run him with the worst or last of the lot. Let him give them both twenty-one pounds. If he does not beat them cleverly, you have no right to expect that he is the best, or nearly the best, horse of his year. I will mention a wonderful trial, when Shark was coming six years old. He ran from the Ditch-In. I borrowed a mare, a good runner, of Mr. Vernon. I think her name was Atlanta, but I cannot mention her name for certain. I gave Mr. Vernon fifty guineas for the hire of her; but then I agreed to have her
for a fortnight before the race, in our stables, that he should not run her to death, by which I might have been deceived in the trial. I promised him to run her only once, from the Ditch-In, and, on the third day, again one mile only, and then to return her. John Oakley rode Shark, and Anthony Wheatly rode the trial mare. Shark gave all the other horses, except the mare, twenty-one pounds. There were three others—my horse St. George, Salopian, and Jack of Hicton. The mare carried four pounds more than them; consequently Shark gave her only seventeen pounds. As the mare and the rest of the horses were coming down the small declivity just past the Furzes on the town side, Shark had beaten them full three hundred yards; so much so, that I rode up to Oakley and told him to pull Shark up, and go in, in the centre of the group. St. George and the mare had a very severe race; he just won it; the other two were beaten three or four lengths.

"St. George had been turned out in a paddock, at my own house, in Berkshire, for ten months, and well fed with corn the whole time. Before I turned him out, I ran him with Salopian, across the Flat, and Salopian beat him shamefully.

"Remember, every horse, including the mare, was of the same age—six years old. Twenty-one pounds is the test of speed; and this your colt must be able to give to one which is a tolerable good runner, and not to one which cannot run at all, or you have not the best, or nearly the best colt of the year.—So much for racing."

After recounting the achievements of some of these old racers, the author of The Horse asks, "What are our racers now?" and answers, "They are speedier, longer, lighter, but still muscular, although shorn of much of their pride in this respect." He continues—"They are as beautiful creatures as the eye would wish to gaze on; but the greater part of them give in before half the race is run; and out of a field of fifteen, or even twenty, not more than two or three of them will live, in the exertion of their best energies, far within the ropes. And what becomes of them when the struggle is over? After the severe racing, as it is now called, of former times, the horse came again to the starting-post with not a single power impaired; and, year after year, he was ready to meet any and every rival. A single race, however, like that of the Derby, now occasionally disables the winner from ever running again; yet the distance is only a mile and a-half. The St. Leger is more destructive to the winner, although the distance is less than two miles. The race of the day has been run; some heavy stakes have been won by the owner; the animal by whose exertions they were gained is led away, and it is sometimes an even chance whether he is ever heard of, or, perhaps, thought of, again. He has answered the purpose for which he was bred, and he has passed away."

By this quotation, it is evident that Mr. Youatt thinks, with Chiffney, that the present character of racers has degenerated. Stoutness has been sacrificed to speed, and the horse has finished the object of his birth and training, when he has won a Derby. But what says the greatest existing authority on this very point.

"A very ridiculous notion exists," says Admiral H. J. Rous, "that because our ancestors were fond of matching their horses four, six, and eight miles, and their great prizes were never less than four miles for equal horses, that the English race-horses of 1700 had more powers of endurance, and were better adapted to run long distances, under heavy weights, than the horses of the present day; and there is another popular notion that our horses cannot now stay four miles.

"From 1600 to 1740, most of the matches at Newmarket were above four miles. The six-mile post, in my time, stood about two hundred yards from the present railroad station—Six-mile Bottom—and the eight-mile post was clear, south from the station on the rising ground; but the cruelty of the distances, and interest of horse-owners, shortened the course in corresponding ratio with the civilisation of the country. Two jades may run as fine a race for eight miles, as for half a mile; it is no proof of endurance. You may match any animals for what distance you please, but it is no proof of great capacity. We have no reason to suppose that the pure Arabian of the desert has degenerated—his pedigree is so well kept; his admirers in the
East are as numerous, and his value in that market has not been depreciated. In 1700, the first cross from these horses, were the heroes of the turf. Look at the portraits of Flying Childers, Lath, Regulus, and other celebrated horses, including the Godolphin Arabian. If the artists were correct in their delineations, they had no appearance of race-horses; they, of course, were good enough to gallop away from the miserable English garrisons of that era, as a good Arab, or Barbary horse, like Vengeance, would run away from a common hackney in the present day. Amongst the blind, a one-eyed man is a king.

"My belief is, that the present English race-horse is as much superior to the race-horse of 1750, as he excelled the first cross from Arabs and Barbs, with English mares; and again, as they surpassed the old English racing hack of 1650.

"The form of Flying Childers might win now a £30 plate, winner to be sold for £40; High-flyer and Eclipse might pull through in a £50 plate, winner to be sold for £200. This may be a strong opinion; it is founded on the faith that, whereas one hundred and fifty years ago, the Eastern horses, in their first cross, were the best and fastest in England; at this day, a second-class race-horse can give five stone to the best Arabian or Barb, and beat him from one to twenty miles. I presume, therefore, that the superiority of the English horse has improved in that ratio above the original stock."

The majority of the plates run for during the last century were given to six-year-old horses, carrying twelve stone four miles, from an impression that a horse should not be trained to run a distance under that age. Before 1770, plates, weight for age, were of rare occurrence. At the commencement of the present century, the inauguration of three and four-mile heats, with ten stone four pounds, to eleven stone six pounds, formed the conditions upon which the royal plates were usually contested. The system of short races, and light weights, was introduced by Sir Charles Bunbury, and the conditions of the royal plates were gradually altered to suit the new style of racing.

However strong may be the conviction, in the minds of some admirers of the horse, that the modern race is degenerating, there are many facts which might be adduced to prove the contrary. As to the matter of stoutness, we think, from all we can learn, there can be no question, notwithstanding the opinion of Admiral Ious. Yet neither Flying Childers nor Eclipse kept the turf for more than two seasons; and we have Catherina running one hundred and seventy-one races, and winning seventy-six times; we have Fisherman running one hundred and twenty races, and winning sixty-nine; we have Euphrates running ninety-two; Isaac, ninety; Zohrab, ninety; and Potentate, eighty-seven. These figures are little indicative of that degree of degeneracy which some writers would endeavour to make us believe has taken place in the breed of our racers.

Having devoted a considerable space to the racers of the last century, we will now briefly record the performances of a few of the present; and passing over Fleur-de-lis, and some others, we may commence with the celebrated

**BEESWING.**

This horse was, in 1833, bred by Mr. W. Dede, of Nunnykirk, Northumberland. Her sire was Doctor Syntax, the winner of twenty-nine races out of forty-four starts. Her dam, by Ardrossan, out of Lady Eliza, by Whitworth, Sylvia, by young Marsh. Her blood is traceable up to the Darley Arabian. She made her public début at Newcastle, in June 1835, for the Tyro stakes, but ran out when in a good place. In 1836 she ran for the great St. Leger, which was won by Elis, the horse of Lord George Bentinck, who, on this occasion, had his animal conveyed in a van, the first time that this mode of conveyance was adopted among racing sportsmen. Beeswing ran eight seasons, starting sixty-four times, and winning fifty. She netted to her owner, seven thousand and eighty pounds.

**ALICE HAWTHORN.**

This fine animal was foaled in 1838, and bred by Mr. John Plummer. Her sire was Mully Moloch, the victor over some of the best horses of his day. In 1854, in his twenty-fourth year, he figures before the world as the sire of eighty-two winners, of whom Alice Hawthorn was the most famous. Her dam was Rebecca, by Lottery. Alice started sixty-nine times, and won fifty and a-half races,
netting, in all, seven thousand eight hundred and ninety-four pounds.

She subsequently fell to the stud; and, in 1857, produced Thormanby.

**BEADSMAN.**

This beautiful horse was the winner of the Derby in 1858, and was bred by Sir Joseph Hawley, baronet. He was got by Weatherbit, out of Mendicant. He was a black-brown horse, standing fifteen hands two and a-half inches high. He had a beautiful blood-like head, with a fine full eye; rather long ears, well set on; a bending neck gracefully joining to his head; great depth of girth, rather light in his back ribs, good loins and back, muscular quarters and thighs; large arms, rather small in the bone, but strong tendons. He very much resembled his dam, the winner of the Oaks in 1846.

**GOVERNNESS.**

This mare was bred by Mr. Gratwicke, and got by Chatham out of a Laurel mare, the dam of Oxonian, Rhedycina (winner of the Oaks in 1850), Student, Instructress, &c. She was a fine strapping animal, standing rather more than sixteen hands and an inch; and a good even-coloured chestnut, without any white, except a blaze in her face; and, for so large a mare, had a good head; powerful and muscular all over, and possessed of a wonderful stride.

The Derbies of '50, '61, '62, '63, '64, '65, and '66, were won successively by Thormanby, Kettelidrum, Caractacus, Macaroni, Blair-Athol, Gladiator, and Lord Lyon.

Such are a few of the racing celebrities we have chosen, to illustrate the running of the present century; and it now becomes a duty briefly to discuss the humanity of the question as to whether the modern system of racing short distances, is preferable to the old system of heats, and long distances. Morally, this is, perhaps, the most interesting portion of our subject, and demands the attention of every man possessed of such sentiments as are inculcated by the gradual development of civilisation.

In *Observations on Breeding for the Turf*, by Mr. N. H. Smith, we find this subject touched upon. "The style of racing now," observes that gentleman, "is totally different from that of former days. At present they run, except at country races, with light weights and short distances, where speed only can excel. Formerly they ran with high weights and long distances, where bottom or stoutness was equally necessary; and hence it may be presumed, that the horse possessing qualities which might have brought him into distinction then, would not be calculated to obtain now an equal fame at Newmarket. It is, therefore, very natural to suppose, that this difference in our style of racing, may, in a certain degree, have altered the character of our racing stock. By a reference to former sporting publications, it appears that the horses were then smaller—most likely shorter in the leg—and, no doubt, capable of carrying weights and running in better than the present racers, which most probably are, generally speaking, longer in the leg, with less substance. It must be allowed that the horse that can go a good distance the best with high weights, is, for all general purposes, and particularly for giving a value to any intermediate breed between the racer and draught-horse, the best sort of horse to resort to as a stallion; but there is something inhuman in the former practice of running four-mile heats with twelve stone weights, which must reduce the speed of the best horse in the world to a pace to which a racehorse ought never to be reduced. It is not racing, but a severe trial of constitutional strength, of the most distressing nature to the poor animal, and better calculated to gratify butchers and hawksers, than the tastes and feelings of gentlemen."

Independent of whatever cruelty might have been exemplified in the length of the former racing-course, there is yet another cruelty which, in the excitement of this sport, is apt to escape general notice. We allude to that which is inflicted by the jockey upon the sides of the animal he rides, by means of spur and whip, urging him on to the utmost of his speed, or rather beyond his utmost, when the animal is literally ready to drop. It ought to be considered an established maxim on the turf, that the efforts of a horse to win a race, are limited only by his physical powers. It is, we believe, generally admitted that the horse enters into the spirit of the race as thoroughly as does his rider; and, without whip or spur,
will generally exert his energies to the utmost to beat his opponent. It is beautiful to see him advancing to the starting-post, every motion evincing his eagerness. The signal is given, and he springs away; he settles himself in his stride; the jockey becomes a part and portion of him, every motion of the arms and body corresponding with, and assisting the action of the horse. On he goes, eager, yet husbanding his powers. At length, when he arrives at that distance from which the rider knows that he will **live home** at the top of his speed, the hint is given, and off he rushes. The race now in reality begins, and every nerve is strained to head his competitor. Then, too, comes the art of the rider, to keep the horse within his pace, and with admirable **give and take**, add to the length of every stride. Then, perhaps, the spur may be lightly and skilfully applied, to rouse every dormant energy.

A sluggish, lurching horse, may need more punishment than the humane observer would think justifiable; but the natural ardour of the race-horse, roused at the moment of the grand struggle, by the moderate application of the whip and spur, will bring him through, if he can win.

An anecdote of Forrester will afford sufficient illustration of the natural emulation of the racer. He had won many a hardly contested race; at length, over-weighted, and over-matched, the rally had commenced. His opponent had been waiting behind, but had now overtaken him, when, till within distance, they continued to be close together. It was a point that could scarcely be decided; but Forrester's strength was failing. He made one desperate plunge—seized his antagonist by the jaw to hold him back, and could be scarcely forced to quit his hold.

In like manner, a horse belonging to Mr. Quin, in 1753, finding his adversary gradually passing him, seized him by the leg, and both riders were obliged to dismount, in order to separate the animals.

With horses such as these, exhibiting the highest evidence of being thoroughly endued with the true emulative spirit, what need for a severe application of the whip or spur? Would the pain, which they by these instruments inflict, have carried such horses over one additional inch of ground? In all probability their lacerations would have been thrown away; they might have shortened the stroke for the animals which, perhaps, would have become enraged, and have suspended every exertion. What says an authority upon this subject.

"Those persons who insist upon an innate quality in what is termed 'blood,' are led to believe that there is something in the nature of a thorough-bred horse which enables him to struggle in a race far beyond his natural capabilities, and which is distinguished by the term 'game.' We do not think there is. We learn from experience, that horses often allow themselves to be beaten by others which are inferior to them, from sheer ill-temper; but their efforts to run a race, we consider to be merely limited by their physical powers, the effect of a proper arrangement of their parts; and that the operation of the mind, or spirit, has nothing at all to do with it. The hero at the Olympic games had, and the champion of the British boxing-ring may have, feelings which, from the superiority of their nature, and the fact of their character, interest, and future happiness being all involved in the event, might have induced them to struggle, even to the very verge of life; but the same sense of honour, and the same spirit of emulation, cannot, at least, in anything like the same ratio, be ascribed to the race-horse. **If his own acting powers be unequal to those of others opposed to him in the race, he yields to that superiority;** although it must be admitted, that what are called sluggish horses will not try to exert themselves to the utmost, unless urged to it by the spur and whip; and others, when spurred and whipped, slacken, instead of increasing their speed."

To this subject it is unnecessary to give further attention here: meanwhile, we may observe, that a diminutive brain is usually associated with dull senses; whilst a large one is generally possessed of much sensibility, sagacity, and courage; but, whatever may be those physiological distinctions or differences, let us always remember, that though

"**The gen'rous horse,**

Restrain'd and awed by man's inferior force,

Does, to the rider's will, his rage submit,

And answers to the spur and owns the bit;"

humanity towards him, as well as towards all
THE HUNTER.

Before entering on a particular description of the horse, to which this portion of our work is to be devoted, we shall enumerate the variety of horses which, under their different apppellations, are characterised by more or less distinctive features. We have already described the racer; but the hunter, the hack, or hackney, the roadster, the lady's horse, or pad; the coach, cavalry, and dray horse, have yet to follow. In sporting language, the term horse indicates one uncut, or a stallion. Gelding has always been a common and familiar term. A horse below thirteen hands—four inches to a hand—in height, is styled a Pony; above that height, and below fourteen hands, a Galloway. The term cob, refers to a truss, short-legged nag, able to carry any weight. The pack-horse has long since disappeared from among us. The cock-tail, a new term in the slang of the inferior turf, indicates a racer not thorough-bred. The weller horse, is a term of long standing, but of unknown derivation. It points to either racer or hunter, master of the highest weight. The designation, thorough-bred, belongs to the racer of pure Arabian or Barb blood; and the term is likewise applicable to the horses of other nations of the south-east. A nag, in which the show of blood predominates, is called blood-like, or a blood-horse. The degrees of blood in an English horse are expressed by the terms, half-bred, three-parts, and seven-eighths bred. The first, or half-bred, is the produce of a racer and common mare, or vice versa—the last cross not so frequent, nor deemed so successful; the second, of the racer and half-bred; and the third, of the racer, and the three-part bred mare. This last may, and has, sometimes, raced capitally. Several examples of successful seven-eighths bred racers, have occurred at various periods. Perhaps no instances have ever occurred, of a three-part bred horse saving his distance in running two miles with thorough-bred racers.

The conventional form of the horse, as to the great essentials, may be held referable to every variety; for example, the head should be lean, argutum caput, neither long nor short, and set on with somewhat of a curve; the thorpple loose and open; the neck not reversed—cock-throppled—but rather arched; the loins wide and substantial; this, more especially, if the back is long; the tail not drooping, but nearly on a level with the spine; the hinder quarters well spread, as a support to the loins, and as a security against the pasterns, in progression, being cut by the hocks; the hinder legs should descend straight, laterally from the hocks, as a preventive to the defect styled sickle-houghed, or hammed; at the same time, the curve from the hock should be so placed, that the feet may come sufficiently forward to prop the loins, and that the horse may not be said to leave his legs behind him; the muscles of the thigh and fore-arm should be solid and full, though some horses are heavy and overdone by nature in those parts. The horse, of whatever description should not be leggy; and, of the extremes, short legs are preferable. The canon, or leg-bone, below the knee, should not be long, but of good substance; and the pasterns and feet, of a size to correspond with the dimensions of the horse; the hoof should be dark, the feet and frog tough, and the heel wide and open; the fore-feet should stand perfectly level, the toe pointing forward in a right line, otherwise the horse will knock, or "cut in the speed," however wide his chest; in plain terms, he will strike and wound either his pasterns, or his legs immediately below the knees, or both; the feet standing even, the horse being equal to his work, will seldom, perhaps never, knock or cut, however near the hoof may approach. A full, clear, azure eye, he also should have.

Such are the requisites of form, whether taken in their widest extremes for the racer or the cart-horse. For the hack, hunter, or racer, there are certain other requisites of form and quality. The principal of these are the deep, backward-declining, and, as it is called, the counter, or coulter shoulder, well elevated fore-hand, deep girthing-place, with sufficient racing blood to give lightness, action of body, and fineness to the hair and skin. This description applies with perfect aptitude to the hunter, which should have, moreover, great strength of loin and fillet, and should not be high upon the leg. Nor is any addition necessary for the running-horse, or racer, but
greater general length, which is the usual result of full or thorough blood. As to our coach-horses, such was wont to be the modern rage for speed, that even our mails and stages might have been said to consist, in a considerable degree, of racers and hunters; and our private coaches of hunting-like horses on a large scale.

In regard to the natural and peculiar form of the slow draught horse, he carries his substance in a round, full, and horizontal manner; his chest is widely developed; his shoulder rather round and bluff than deep, and its summit, the apex, or top of the fore-hand, not high and acute, but wide. Such a form seems best adapted to the collar, and to enable the animal to draw, or move forward, heavy weights; yet, nevertheless, daily see numbers of first-rate draught horses with deep flat shoulders. It used to he held, that a low shoulder facilitated draught; and such was the form of the old Suffolk sorrel cart-horses, the truest and most forceful pullers of their kind. They were the only breed, collectively, that would draw dead pull; that is to say, would continue repeated pulls, going down upon their knees to an immovable object—for example, a tree. This, draught horses in general, even the most powerful and the best, cannot be brought to do, whatever may be the severity used towards them; at the second or third pull, gibbing, as it is called, and turning their heads, as if to point with their eyes, towards their failing loins, is a common circumstance.

Such are the general characteristics of the lower grades of horses; and taking the middle of Charles the First’s reign, as the date of the introduction of the Eastern animals into this country, it allows us about two centuries and a quarter for the manufacture of the English thorough-bred horse, in his form as he is found in Great Britain, and in Great Britain only. To preserve him in his purity, Arab and Persian mares were, also, imported at the same period, their produce then, as now, being considered and treated purely with reference to the turf, as their ultimate destination. The cross between the Arab stallions and the native mares, was held as the fittest for the field—strength, with a little breeding, enabling any kind of equine flesh on four legs, to canter from daylight to noon, alongside the long-cared, short-legged barrier, or beagle of that day.

The hunter is generally a horse between fifteen and sixteen hands in height, from the half-bred to the thorough-bred species; and ought to be of a lofty fore-hand, and shoulder well formed for action, with wide and substantial loins, moderately short legs and pasterns, and sound feet. The fashion of riding full-bred and speedy horses, so prevalent of late years, was equally prevalent in the beginning; indeed, was original in the system. But this chiefly takes place in light-soiled counties. Upon strong and heavy soils, a powerful, well-shaped, half-bred horse, may perform satisfactorily, and make a good figure; but upon light lands and downs, the speed of the high-bred courser is too much for his powers, and he cannot long hold his way in such superior company. On a general consideration, the three part or seven-eighth bred horse is best adapted for hunting—since, at the same time, acknowledging the superiority of the thorough-bred horse, it is so extremely difficult to obtain him of that make and form which shall sufficiently combine strength with speed, to fit him for his duties.

Hunting is obviously one of the most severe labours of the horse, yet one that is so generally attractive to him, that there are well-authenticated anecdotes of old hunters, inspired by the music of their fellow-sportsmen, the hounds, breaking pasture over the most dangerous fences, following the chase, and coming first in at the death.

Until he has attained his sixth year, the joints of a horse are not sufficiently fixed to carry him well through a season’s hunting; although, at five, he should be cautiously and moderately used in the field. His education consists chiefly in being taught to leap the bar, standing, since generally all horses will take a flying leap, in some manner or other. The practice of surzing the leaping-bar around, is well known; but some grooms are too harsh and hasty with the young horse, whence many animals, of irritable tempers, can never afterwards be made staunch leapers. One of the most extraordinary leaps made by a horse was done at Birmingham, by an animal belonging to a Mr. Beardsworth. On the ground being
accurately measured by some gentleman who witnessed the performance, it was found that, in passing over a bar three feet six inches high, the leap was taken at the amazing distance of seventeen feet seven inches from it, and the whole space of ground covered was twenty-seven feet eight inches. The horse was fifteen hands and a-half high, and carried upwards of twelve stone. He was afterwards ridden over the same bar several times, and cleared upwards of eight yards without much apparent effort.

The first property of a good hunter is, that he should be light in hand. For this purpose, his head must be small; his neck thin, and especially thin beneath; his crest firm and arched, and his jaws wide. The head will then be well set on. It will form that angle with the neck, which gives a light and pleasant mouth.

The fore-hand should be loftier than that of the racer. A turf horse may be forgiven if his hind quarters rise an inch or two above his fore ones. His principal power is wanted from behind; and the very lowness of the fore-hand may throw more weight in front, and cause the whole machine to be more easily and speedily moved. A lofty fore-hand, therefore, is indispensable in the hunter; the shoulder should be as extensive as in the racer; also as oblique, and somewhat thicker; the saddle will then sit in its proper place, and will continue so, however long may be the run.

The barrel should be rounder, to give greater room for the heart and lungs to play, and send oxygenised blood in greater quantities to the larger frame of this kind of horse; room to play is all the more essential when the run continues unchecked for such a length of time as to begin to be distressing. A broad chest is an excellence in the hunter. In the violent and long-continued exertion of the chase, the respiration is exceedingly quickened, and a great deal more blood is hurried through the lungs in a given time, than when the animal is at rest. There must be sufficient room for this, or the beast will be blown, and possibly destroyed. The majority of the horses that perish in the field are narrow-chested.

The foot of the hunter is a most material point. It is of consequence in the racer; yet it is a notorious fact, that numbers of our best thorough-bred horses have had very indifferent feet. The narrow contracted foot is the curse of many of the racing blood. The work of the racer, however, is all performed on the turf, and his bad feet may scarcely incommode him; but the foot of the hunter is battered over many a flinty road and stony field; and if not particularly good, will soon be disabled and ruined.

The position of his feet, also, requires attention. They should, if possible, stand straight. If they turn a little outward there is no serious objection; but if they turn inward, his action cannot be safe, particularly when he is fatigued or over-weighted.

The body should be short and compact, compared with that of the race-horse, that he may not, in his gallop, take too extended a stride. This, in a long day, and with a heavy rider, would be a serious disadvantage, from the stress on the pasterns; and more serious when going over clayey ground, during the winter months. The compact, short-strided horse will almost skim the surface; while the feet of the longer-reached animal will sink deep, and he will wear himself out by efforts to disengage himself.

The hunter may be fairly ridden twice, or if not with any very hard days, thrice a week; but, after a thoroughly hard day, and evident distress, three or four days' rest should be allowed. They who are merciful to their horses, allow about thirty days' work in the course of the season; with gentle exercise on each of the intermediate days, and particularly a sweat on the day before hunting. There is an account, however, of one horse which followed the fox-hounds seventy-five times in one season. We are not aware that this feat has ever been exceeded.

We have before said that the horse fully shares in the enthusiasm of his rider; and it is beautiful to watch the old hunter, who, after many a winter's hard work, is turned into the park to enjoy himself for life. His attitude and his countenance when, perchance, he hears the distant cry of the dogs, are a study for the contemplation of the artist.

"I was entertained by listening to an Arab peasant," says Sir John Malcolm, in his _Sketches in Persia_, describe a fox-hunt which he had seen in the English style. 'There
came the fox-devil; he pointing with a crooked stick to a clump of date-trees; there he came at a great rate. I hallooed, but nobody heard me, and I thought he must get away; but, when he got quite out of sight, up came a large spotted dog, and then another, and another. They all had their noses to the ground, and gave tongue—whow, whow, whow—I was frightened. Away went these devils, who soon found the poor animal. After them galloped the Feringees (a corruption of Frank, the name given to a European over all Asia), shouting and trying to make a noise louder than the dogs. No wonder they killed the fox among them."

The following is related by a Wiltshire gentleman, who was an eye-witness of the scene he describes:—"I lent a fine and fiery mare to a friend from town, who had come down to try his Essex dogs against our Wiltshire breed: at the close of a very fine day's sport, we had to beat a small furze-brake, and, for the purpose of better threading it, my friend dismounted and gave the bridle of the mare to the next horseman. Puss was soon started; the "halloo" was given; the person who held my mare, in the eagerness of sport, forgot his charge, loosed his hold, and, regardless of any other than his own steed, left mine to run, like Mazeppa's, "wild and untutored."

But, to the astonishment of all, instead of so doing, or even attempting to bend her course homewards (and she was in the immediate neighbourhood of her stable), she ran the whole course at the tail of the dogs; turned, as well as she could, when they brought the prey about, and afterwards by very much outstripping all competitors (for the run was long and sharp), she stopped only at the death of the hare, and then suffered herself to be quietly regained and remounted. This I conceive to be certainly an extraordinary proof of a natural love for the sport; but what renders it more remarkable is, that I had only attempted to ride her twice before, after any hounds whatever. The brace of dogs that were slipped at this course were my own, and the groom had been in the habit of exercising them with the mare. Whether this had any effect on her actions I am not competent to give an opinion."

The passion of horses for hunting was, on one occasion, exemplified in a most extraordinary manner. Three of the horses of the Brighton coach chanced to have finished their stage, and to have been standing, unharnessed, at the instant Lord Derby's stag-hounds passed in full cry. They started off and joined the hunt, and had the gratification of a run of some length, until the hounds were whopped off. Even after this, they followed the stag till they got up to his haunches, and then chased him three miles on the high road, when the stag taking a high fence, left them snorting on the wrong side, to be secured by those in quest of them.

This deer was more fortunate than one which was hunted by the same pack, as the result will show. Some years since, the Earl of Derby turned out from the Oaks a noble deer, for a day's sport, which, after having traced a very long tract of country, entered the grounds of the late Mrs. Smith, of Ashford, near Epsom, Surrey, and being closely pursued by the hounds, it actually leaped through the drawing-room window, the sash of which was down, followed by the pack in full cry. The consternation occasioned in the family, by this strange event, was indescribable. At that critical moment no one was in the apartment, some ladies having quitted it a few minutes previously. The window was almost dashed to atoms, and every part of the room, with its rich carpet and corresponding furniture, covered with blood and dirt. The animal was soon dispatched by the ferocity of the dogs; and perhaps so curious an event is not to be found in the annals of sporting. As a companion, however, to this scene, a stag, graduating towards the city of Oxford, at length took to one of the streets, through which he was followed by the hounds in full cry, into a chapel, and there killed, during divine service.

A horse that had, a short time before, been severely fired on three legs, and was placed in a loose box, with the door, four feet high, closed, and an aperture over it little more than three feet square, and standing himself nearly sixteen hands, and master of fifteen stone, hearing the cheering of the huntsmen and the cry of the dogs at no great distance, sprung through the aperture, without leaving a single mark on the bottom, the top, or the sides.

If the horse, then, be thus ready to exert himself for our pleasure—and pleasure alone
is here the object—it is indefensible and brutal to urge him beyond his own natural ardour, so severely as we sometimes do, and even until nature is quite exhausted. It is, perhaps, not now so frequent; but formerly we scarcely ever heard of a "hard day," without being likewise informed, that one or more horses either died in the field, or scarcely reached home before they expired. Some have been thoughtless and cruel enough to kill two horses in one day. One of the severest chases on record was by the king's stag-hounds. There was an uninterrupted burst of four hours and twenty minutes. One horse dropped dead in the field; another died before he could reach the stable; and seven more within a week afterwards.

It is easily conceivable, and it does sometimes happen, that, entering as fully as his master into the sports of the day, the horse diadains to yield to fatigue, and voluntarily presses on, until nature is exhausted, and he falls and dies. Much oftener, however, the poor animal has, intelligibly enough, hinted his distress; unwilling to give in, yet painfully and falteringly holding on; when the merciless rider, rather than relinquish one hour's enjoyment, tortures him with whip and spur, until he drops and expires.

However unwilling the hunter may be to abandon the chase for the time being, he who "is merciful to his beast" will soon recognise the symptoms of excessive and dangerous distress. To the drooping pace, staggering gait, heaving flank, and heavy bearing on hand, will be added a very peculiar noise. The inexperienced person will fancy it to be the beating of the heart; but that has almost ceased to beat, and the lungs are becoming gorged with blood. It is the convulsive motion of the muscles of the belly, called into violent action to assist in the now laborious office of respiring.

In this dangerous situation, life almost quivering in the horse's nostrils, Mr. Youatt says—

"Let the rider instantly dismount. If he has a lancet, and skill to use it, let him take away five or six quarts of blood; or if he has no lancet, let him cut the burs with his pocket-knife as deeply as he can. The lungs may be thus relieved, and the horse may be able to crawl home. Then, or before, if possible, let some powerful cordial be administered. Cordials are, generally speaking, the disgrace and bane of the stable; but here, and almost here alone, they are truly valuable. They may rouse the exhausted powers of nature; they may prevent what the medical man would call the reaction of inflammation; although they are the veriest poison when inflammation has commenced.

"A favourite hunter fell after a long burst, and lay stretched out, convulsed, and apparently dying. His master procured a bottle of good sherry from the house of a neighbouring friend, and poured it down the animal's throat. The horse immediately began to revive; soon after got up, and walked home, and gradually recovered. The sportsman may not always be able to get this, but he may obtain a cordial-ball from the nearest farrier, or he may beg a little ginger from some good house-wife, and mix it with warm ale, or he may give the ale alone, or strengthened with a little rum or gin. When he gets home, or if he stops at the first stable he finds, let the horse be put into the coolest place, and then well clothed, and diligently rubbed about the legs and belly. The practice of putting the animal, thus distressed, into 'a comfortable warm stable,' and excluding every breath of air, has destroyed many valuable horses.

"We are now describing the very earliest treatment to be adopted, and before it may be possible to call in an experienced practitioner. This stimulating plan would be fatal twelve hours afterwards. It will, however, be the wisest course, to commit the animal, the first moment it is practicable, to the care of the veterinary surgeon, if such there be in the neighbourhood, in whom confidence can be placed."

The labours and the pleasures of the hunting season being passed, the farmer makes little or no difference in the management of his untrained horse; but the wealthier sportsman is somewhat at a loss what to do with his. It used to be thought, that when the animal had so long contributed to the enjoyment of his owner, he ought, for a few months, to be permitted to seek his own amusement, in his own way, and he was turned out for a summer's run at grass.
The pages of the *Sporting Magazine* contained, some years back, a controversy on the merits of summering the hunter. Two celebrated writers were engaged in it; one under the signature of Nimrod, who recommended summering the hunter in the stable; the opponent to this measure was the veteran John Lawrence, who advocated the summering of the hunter in the field as the best means of renovating him, and restoring him to his pristine vigour. This controversy was carried on in no very measured or complimentary terms.

The practice, however, of turning out the hunter seems to us so natural as well as beneficial to the animal, that we feel surprised that a dispute upon such a question could have arisen. The following remarks upon this subject seem so judicious, that we cannot withhold them from our readers. They proceed from the same writer on the *Horse*, to whom we have before alluded.

"Fashion, which now governs everything, and now and then cruelly and absurdly, has exercised her tyranny over this poor quadruped. His field, where he could wander and gambol as he liked, is changed to a loose box; and the liberty in which he so evidently exulted, to an hour’s walking exercise daily. He is allowed vetches, or grass occasionally; but from his box he stirs not, except for his dull morning’s round, until he is taken into training for the next winter’s business.

"In this, however, as in most other things, there is a medium. There are few horses who have not materially suffered in their legs and feet, before the close of the hunting season. There is nothing so refreshing to their feet as the damp coolness of the grass into which they are turned in May; and nothing so calculated to remove every enlargement and sprain, as the gentle exercise which the animal voluntarily takes while his legs are exposed to the cooling process of evaporation, which is taking place from the herbage he treads. The experience of ages has shown that it is superior to all the embrocations and bandages of the most skilful veterinarian. It is the renovating process of nature, where the art of man fails.

"The spring grass is the best physic that can possibly be administered to the horse. To a degree, which no artificial aperient or diuretic can attain, it carries off every humour which may be lurking about the animal; it fines down the roundness of the legs; and, except there be some bony enlargement, restores them almost to their original form and strength. When, however, the summer has thoroughly set in, the grass ceases to be succulent, aperient, or medicinal; the ground is no longer cool and moist, at least during the day; and a host of tormentors, in the shape of flies, are, from sunrise to sunset, persecuting the poor animal. Running and stamping to rid himself of his plagues, his feet are battered by the hard ground, and he newly, and perhaps more severely, injures his legs. Kept in a constant state of irritation and fever, he rapidly loses his condition, and sometimes comes up to August little better than a skeleton.

"Let the horse be turned out as soon as possible after the hunting season is over. Let him have the whole of May, and the greater part, or possibly the whole of June; but when the grass fails, and the ground gets hard, and the flies torment, let him be taken up. All the benefits of turning out, and that which a loose box and artificial physic can never give, will have been obtained, without the inconvenience and injury which attend an injudiciously protracted run at grass, and which, arguing against the use of a thing from the abuse of it, have been improperly urged against turning out at all."

Stable-summering the hunter is favourably considered by Count Veltherin. "I hope," he says, "I may be permitted to adduce something from my own experience, having, for nearly thirty years, constantly had at my country seat from seventy to eighty horses—partly saddle, partly coach, draught, and breeding horses and colts; and that, from prolification to horses, I have always bestowed particular attention upon them. For a long time it has not been customary, on well-managed estates in this part of the country, to turn horses to grass in summer, or to give them green food in the stable, with the exception of brood mares and their foals."

Mr. Appleby, in his *Letters on Condition*, thus states his method of summering the hunter:—"The first step I should take would be to put the horse into a loose box, if convenient, and, by degrees, diminish his corn,
giving him an hour's walking exercise as usual. I should then give him two doses of physic, which would not only cool his habit of body, so as to prevent the danger of inflammatory attacks, but would have such an effect on his legs as would enable me to see what injury had been done to them in his work, whether there were any ligamentary enlargements, any injury to the joints or sinews, any callous substances produced by blows; or, in short, anything going wrong. The clear state of his legs, which this treatment will produce, would prevent the possibility of working in the dark, as they will become prier—to use the language of grooms—in three weeks, than they would at the expiration of three months' run at grass in the summer." Mr. Appleby, however, further observes, that, under favourable circumstances, he would strongly recommend turning out. "In case of having recourse to blistering, it is most serviceable; and, after spring, almost necessary; but then the hunter should be turned out only at night, and into a place where there is but little grass, and have two, if not three feeds of corn a-day; but nothing else to eat till he goes out, unless it be a few vetches, for four or five days at a time, when they are young and tender, in the months of May or June; but these should not be repeated more than three or four times, as they tend to make horses very foul; and when in pod are most injurious to them."

When we come to speak of the economy of the stable, we will also treat of the management of the hunter.

THE HACKNEY.

A Hack, in the modern stable phrase, signifies a road horse, and not merely a horse let out to hire, as some of the uninitiated suppose. The road horse is more difficult to meet with in perfection than even the hunter or the courser. There are many reasons for this. The price of the hackney, or the horse of all work, is so low, that he who has a good one, will not part with him; and it is by mere accident that he can be obtained. There are also several faults which may be overlooked in the hunter, but which the road horse must not have. The hunter may start, may be awkward in his walk, or even his trot; he may have thrushes or corns; but if he can go a good slapping pace, and has wind and bottom, he can both be put up with and prized; but the hackney, if he be worth having, must have good fore-legs, and good hinder ones too; he must be sound on his feet, even tempered, no starter, quiet in whatever situation he may be placed, not heavy in hand, and never disposed to tumble down.

The hackney, like the hunter of the present day, is always a horse with some portion of racing blood; the whole English race, even to the cart-horse, being more or less imbued, and equally improved by it. Thus our road horses are half, three parts, seven-eighths, or thorough-bred. The two latter degrees are, in several respects, not so well fitted for the purpose of travelling as the former: chiefly on account of the tenderness of their legs and feet, their longer stride, and straight-kneed action, not so well adapted to the English road pace, the trot. Nevertheless bred hackneys are elegant and fashionable, and, when good canterers, pleasant to ride; insomuch, that a certain colonel of the guards of former days, insisted there was the same difference to be felt in riding a bred hack and one without blood, as between riding in a coach and in a cart. One good property in thorough-bred road horses is, that they seldom shy—many of them never.

The road horse should have a considerable, lofty, yet light fore-hand or crest; a deep and extensive shoulder; be well raised at the withers; straight backed, and have substantial loins and wide fillets, the croup not suddenly drooping, nor the tail set on low. The head should not be thick and fleshy, nor join abruptly to the neck, but in a gradual or tapering form; the eye full, clear, and diaphanous. The fore-arms and thighs, with plenty of muscular substance, should be of reasonable length, but the legs should, at no rate, be long. Much solid flat bone beneath the knee, is a great perfection in a hackney; and the feet, standing straight, turning neither inwards nor outwards, should be of tough, dark, shining horn, and the heels wide and open. The saddle-horse's fore-feet should closely approach each other, the wide chest being rather adapted to the collar. Notwithstanding this near approximation of the fore-feet, no apprehension need be entertained of the horse's cutting himself in speed, or
knocking his pastern joints, since these defects arise almost invariably from the irregular pointing of the toe, inwards or outwards, for which, neither a wide chest nor the most skilful farriery has ever yet provided a sufficient remedy. A saddle horse, of any description, can scarcely go too close before, or too wide behind.

Perhaps the best pedigree for a road horse to have, is to be bred from hackney stock on both sides, more particularly for a trotter. The high road is the proper theatre of exercise for such horses; but there may be sometimes a necessity for exercising them on the pavement, as is the case in London, where the pace should never exceed the slow trot.

The author of The Horse says—"The hackney should be a hunter in miniature, with these exceptions. His height should rarely exceed fifteen hands and an inch. He will be sufficiently strong and more pleasant for work below that standard. He should be of a more compact form than the hunter, and have more bulk, according to his height; for he has not merely to stand an occasional, and perhaps severe burst in the field, but a great deal of every-day work. It is of essential consequence that the bones beneath the knee should be deep and flat, and the tendon not hid in. The pastern should be short, and although oblique or slanting, yet far less so than that of the racehorse. There should be obliquity enough to give pleasant action, but not to render the horse incapable of the wear and tear of constant and, sometimes, hard work. The foot is a matter of the greatest consequence in the hackney. It should be of a size corresponding with the bulk of the animal—neither too hollow nor too flat; open at the heels, and free from corns and thrusts. The fore-legs should be perfectly straight. There needs not a moment’s consideration with the public, to be convinced that a horse with his knees bent, will, from a slight cause, and especially if he is over-weighted, come down. The fact, however, is, that a horse with bent fore-legs has rarely broken knees. The back should be straight and short, yet sufficiently long to leave comfortable room for the saddle between the shoulders and the haunch, without pressing on either. Some persons prefer a hollow-backed horse. He is generally an easy one to go. He will canter well with a lady; he may not carry so heavy a weight, nor stand such hard work, but it is a great luxury to ride him. The road horse should be high in the fore-hand, round in the barrel, and deep in the chest; the saddle will not then pass too forward, but the girths will remain firmly fixed in their proper place."

A good hack will travel fifty or sixty miles a day with ease; but for long-continued journeys, thirty or forty miles a day is as much as should be required. Let no man expect great performances, unless his horse be full of hard meat, and in condition. Should a man be forced to ride an animal a journey with his full burden of grass-flesh upon him, he must at first ride him moderately; and by virtue of good solid corn-feeds, his horse will, in a month, attain condition.

Many persons ride long stages—say thirty or forty miles—without feeding; but it is incon siderate, and is injurious to the horse. Moderate feeds at the different stages, and an ample one at the last, are most beneficial; a quarter of oats, with a handful or two of beans, are sufficient quantities during the day; at night, half a peck of oats and a few handfuls of beans; so that a hack upon a journey of considerable length, may be allowed from a peck and a quarter, to a peck and a half of oats. Hasty travellers will yet find an advantage in starting at a very moderate pace, and in finishing the last three miles of a stage, especially in hot weather, as leisurely as their haste will admit, since, by such means, they will save time; as their horses, on reaching the inn, will be the sooner dry, and ready to feed. On the road, the horse may be indulged, every eight or ten miles, if he requires it, with a few go-downs of water; and in hot weather, over hard roads, and with fast travelling, when the shoes acquire a burning heat, it is most refreshing to the animal to ride him over his pasterns, momentarily, through any water that may be accessible. But a caution of much moment must have place here. Be the weather hot or cold, a horse in a state of perspiration, should never be kept standing any length of time in water.

In fast travelling, every horseman of common sense will ease his hack up the hills; in going down also, if he values his own neck and his horse’s knees, he will do the same.

We have heard of a respectable butcher, who
kept some good horses. He had a famous mare that carried him from Birmingham to Nottingham and back within the twelve hours. This was no mean performance, the distance there and back being close upon a hundred miles. The butcher spoke of it as not being much of an effort. He said the general pace of his horse was eleven miles an hour, and on going down hill he sometimes dismounted, which he considered to be very refreshing to the mare, he being a heavy man.

When a hack, always known to ride quiet, does not set off readily, or makes a stop on the road, the rider may be assured that it arises from some sudden painful bodily affliction, or something misplaced and galling in his furniture. The rider should instantly dismount, and examine both horse and tackle, at all points. The animal may be suddenly gripped, or seized with a fit of strangury, which will appear from his dilated nostrils, sweating at the ear-roots, staring coat, and attempts to stale. Aged and worked hackneys are liable to the strangury; in which case, all the rider can do is to lead him about gently, and give him time to void the dripping urine.

Arrived at the inn, and the horse cool, no extra care or solicitude is required; he may be led into the stable, stripped, rubbed over, whilst eating a lock of hay, and soon be ready for his feed of corn.

There is nothing more refreshing to a hard-ridden animal, and for abating the excessive and painful heat and tension in his joints and sinews, than to have his feet and legs well washed and bathed in warm water. It is a good precaution used, if the inside of the saddle be made dry and comfortable. If he should not feed well, nor eat his corn with an appetite, it is a hint that rest would be acceptable; and it should be complied with.

It will be wise to keep the old adage in view, "that a master's eye makes his horse fat;" either himself or his groom should attend at every feeding-time, to see that the horse has justice done in his food, as to quality as well as quantity.

There are many highly interesting anecdotes illustrative of the intelligence of the hackney. Seldom do we meet with so near an approach towards mind in the brute creation, as was evinced by a horse of Horncastle, Lincolnshire.

A Mr. Treevor, of this place, was in possession of a horse, which was, at times, let loose in a yard adjoining the stable, where stood a pump and a water-trough. This horse was endowed with an amount of sagacity rarely possessed by the same species. He actually could pump from the well the water he wished to drink. As the pump was frequently used by many persons in the course of a day, it was supposed the docile animal had learned this extraordinary art by noticing them. As the yard which surrounded the pump was always open to public inspection, many persons have seen him elevating the handle with his nose, and then pressing it down in the same way. Such of our readers as may have experienced the corroding bitterness of that sorrow which the unkindness of prejudiced neighbours inflict, will doubtless admire, as a pleasing trait in the character of this noble animal, the amiable instinct, the generous friendship which inclined him to supply a fellow-companion, another horse in the same yard, with a daily banquet from the trough, into which he pumped for him a sufficiency of water, even before he attempted to satisfy himself. Such an instance of neighbourly kindness is rarely exhibited, even among mankind, far less among animals of a much inferior race, and not possessed of even the highest quadrupedal instincts.

Again, a horse having been turned into a field by its owner, Mr. Joseph Lane, of Fascombe, in the parish of Ashelworth, was missed the next morning, and the usual inquiries were set afoot, as to what could have become of him. He had, it seems, been shod a few days before; and, as it frequently happens, got pinched in one of his feet. Feeling, no doubt, a lively sense of the necessity of being properly shod, and desirous of relieving the cause of pain, he contrived to unhang the gate, which opened into his pasture, with his mouth, and make the best of his way to the smithy—a distance of a mile and a-half from Fascombe—where he waited respectfully at the door, until the bungling artist got up. The smith relates, on opening his shed, that he found him there; that the horse advanced to the forge, and held up his ailing foot; and that he himself, upon examination, discovered the injury, took off the shoe, and replaced it more carefully, which having done, the sagacious creature set off at
a merry pace homewards. Soon afterwards Mr. Lane's servants passed by the forge in quest of the animal; and, upon inquiry, received for answer—"Oh, he has been here, and got re-shod, and is gone home again."

A curious instance of the faculty of memory exhibited in a hackney, occurred at Bristol, some years ago. A person recognised a horse, bestrode by a countryman, to be one which he himself had lost about nine months before. He seized his property, and put in his claim. "This is my horse, and I will prove it in two minutes, or quit my claim." He then liberated the animal from restraint, let him go at large, and declared his proof to be in the fact that the horse would be found at his stables at some distance; a circumstance verified in a few minutes, by the two claimants and several bystanders repairing to the stables, where they found the horse "quite at home."

The hackney has often figured in trotting-matches, a few of which have, from time to time, found their way into print, even beyond the ephemeral fame of a sporting paper.

A curious match once took place on the Beaconsfield-road, when a Mr. Canston undertook to trot his horse seven miles in half-an-hour; and accepted bets that he performed each mile within four minutes and twenty-two seconds—a piece of nice calculation, which was achieved in good style.

A horse belonging to Mr. Dyson, which had been picked up in Smithfield for a trifle, having accomplished thirty miles in two hours and forty-nine minutes, was produced by Mr. Brian against another, which cost seven pounds, to perform forty miles in four hours, carrying fifteen stone. This struggle "came off" over a ten-mile piece of road, near Hockerill, for one hundred guineas. The hackney nature emblem of blood and bone, above seventeen hands high, was mounted by an old jockey of the same build, and did the first ten miles in fifty-four minutes ten seconds, the second ten miles in fifty-six minutes fifty seconds, the third ten miles in sixty-three minutes, and the fourth ten miles in sixty-three minutes forty seconds—winning by two minutes and twenty seconds under the time. The horse never once broke from a trot; and the rider was more fatigued than the animal he bestrode.

The second great match between the slate-coloured American horse, and Mr. Dyson's Wonder, was another extraordinary instance of trotting. It took place on Sunbury-common. The match was for Mr. Fielder and Mr. Dyson to ride their own horses. Mr. Dyson took the lead, and was fifty yards a-head at the end of the first mile, and the American horse never had a chance at any one period, and was beaten with the greatest ease, by about two hundred yards. Neither horse broke through the match, and the ground—three miles—was done in eight minutes and forty-three seconds. What makes this performance the more wonderful, is not only the speed, but the extraordinary weights which were carried. The riders were both weighed, to determine a bet, at Kingston, after the match, when Mr. Fielder was found to be thirteen stone twelve pounds, and Mr. Dyson fifteen stone four pounds, without saddles. By this it appears that the winner gave the American horse twenty pounds. The slate-coloured horse was considered, for years, the best in America. Another horse belonging to Mr. Williams, beat the slate-coloured American, and was backed to trot three miles in nine minutes, for one hundred guineas. It had been reported that the horse was lame, and, up to the evening before starting, six to four was the betting on time, and more than two to one was betted before starting. When at speed the lameness was not apparent; but the horse was more than three minutes doing the first mile, and there was no increase of speed during the match. The horse broke into a gallop near the George Inn, when about one hundred yards from home; and the pressure of horsemen was so great at his heels, that the jockey turned him with difficulty, and the match was lost by forty seconds. Some thousands were depending on this race.

A hackney mare, of Mr. Dixon, of Barbican, started at the four-mile-stone on the Romford-road, to trot thirty miles in three successive hours, carrying Mr. J. Coxeter, weighing nearly fifteen stone. Notwithstanding the heavy weight the mare carried, she performed the distance in thirteen minutes and twenty-seven seconds within the given time.

So long ago as 1785, a similar match was
made to trot thirty miles in two hours and a-half, and the accounts state that this was accomplished, leaving four minutes to spare.

Tom Thumb, an American cob, trotted one hundred miles in harness, over five miles of road on Sunbury-common, in ten hours and twenty-three minutes; and this was considered, and admitted to be, an extraordinary feat.

Rattler, another American, the property of the same proprietor, beat the celebrated Welsh mare, Miss Turner, over ten miles of ground between Cambridge and Godmanchester, going the distance in thirty minutes and forty seconds; and this was certainly a feat unprecedented in the annals of trotting in this country. The same animal, driven by Mr. Osbaldeston, his then master, performed five miles of road, between Wittlesey-bridge and Royston, in thirty minutes fifty-eight seconds, beating Mr. Payne’s Rochester, an American entire horse, whose nose touched the wheel of the squire’s cart on passing the winning-post. Rattler, ridden by his master, beat Mr. Lawton’s Driver—a pony which had performed seventeen miles within the hour—trotting thirty-four miles in two hours, eighteen minutes, and fifty-six seconds.

If, however, the feat of Tom Thumb was considered unprecedented, we have to record a time-match which leaves his performance in the shade—that of a mare, the property of Mr. Dixon, of Knightsbridge, which went over precisely the same ground, and completed the hundred miles in nine hours, fifty-six minutes, and fifty-seven seconds! A match cart had been provided for the occasion; and, at twenty minutes to six o’clock on an April morning, the mare started, driven by Mr. W. Stacey, a farmer residing in the vicinity of Kingston, under whose surveillance she had been in training since the previous November, when the match was made. She finished her first twenty miles, with great spirit, in two minutes less than two hours, and was then taken out, and had some gruel given her. In three minutes and a-half she was again on the move, and rather increased her speed in the next twenty miles, to make up for her stoppage, but was still within the four hours; and thus she continued, at the same pace, till she had completed eighty miles, finally winning with three minutes and three seconds to spare! She showed no symptoms of fatigue; and, on entering her stable, began to eat her hay as if she had only come off a moderate stage. After resting an hour, she was gently walked to her training-stable, a distance of seven miles, and continued well afterwards. During her match, she was taken out at the completion of every twenty miles, and cordial-balls, washed down with gruel, administered on each stoppage.

This mare was all English, and no doubt was entertained that she could have accomplished her undertaking in less time. So confident, indeed, was her trainer in her powers, that he offered to back her to do the same distance in nine hours and a-half.

Captain Halford’s match to trot eight miles and a-half in half-an-hour, and to carry eleven stone, with a horse bona fide his property, for one hundred guineas; and a second match, for a like sum, took place over a two-mile piece of ground at Merston Vale. The eight miles and a-half were done in twenty-nine minutes and fifty-seven seconds.

A manoeuvre, not dreamt of, was here practised; a jockey of ten stone immediately mounted the same horse, and proceeded on the second match, to the astonishment of all present. The match was lost by thirteen seconds.

Of the comparative merits of the horse and the pony, as hacks, a good judge thus writes:—

"It is, and has for a long time been, a favourite opinion of mine, that a good pony is the best rough-and-ready hack in the world. In a pony is contained, within a small space, what one might call the concentrated essence of strength and speed.

"It is generally supposed, and I am persuaded of the correctness of the supposition, that if you want to ruin a young horse, your best plan is to starve him whilst he is young. Every rule, however, has its exception, and the case of the forest ponies is a most marked exception to this one. Starved in his early youth, the Forester, though small and stunted in appearance, is endowed generally with a more hardy constitution and more untiring endurance, than any other species of horse in this country. Until he is three years old, the forest pony is scarcely looked after, and then
he is taken up by his poor proprietor, exhibiting a shaggy coat, an immense pot-belly ewe neck, big head, and ragged mane and tail. To look at him in this stage of his career, you would suppose that a full-grown donkey was more than an equivalent as an exchange for the animal calling himself a horse, in the style in which he appears. If his owner cannot sell him immediately, he puts him into his cart, and he is supported by a lock of hay at night. The poor animal becomes crippled, by hard work put upon him, in his fourth year; and is, therefore, consigned to the cart of the costermonger or travelling tinker, there to drag on, in hunger and toil, the existence which commenced in hardship and privation.

"But let us turn from this scene of woe, and suppose our pony born under a more auspicious star. A gentleman sees him when he is first caught; and as he flatters himself he is a bit of a judge, observes a good point or two; he has plenty of good feed to spare, and takes compassion upon the poor starveling's hard lot. After a summer and autumn of good living, with an improved appearance, and a splice of wickedness in his eye, the pony is, in the winter, driven into the straw- yard, and shares with the crows all the little comforts of a warm and sheltered shed by night, and a crib well filled with hay by day. During this time his master sees what an improvement has taken place in his nag, and, in the spring, gives orders for him to have a little taste of the saddle and bridle in the way of breaking in. Physicked, stabled, and clothed, the dust of four years is, with no little difficulty, extracted from his jacket, and his natural colour is at length opened to the view. He is at last mounted by his master, who discovers that the ragged rascal bought by him out of charity, is by no means unworthy of his purchase-money: he congratulates himself upon his bargain; and always supposing our gentlemen to be a light weight—about ten, but certainly under eleven stone—he discovers, when his nag is five years old, and in good condition, that he is, without any exception, the best hack that he ever obtained at any price; and, moreover, that by means of good and generous keep, his personal appearance is so wonderfully altered and improved, that no one could have recognised in him the least degree of likeness to the puny forester, that was purchased at the edge of the common for the very sporting price of eight pounds!

"Such, reader, has been the case with me; and I shall ever bless the hour when I rescued from the cart of the costermonger, my gallant little grey. Of course, for hunting, nothing but a full-sized horse will do, whatever be a man's weight; but for coursing and hacking about, give me a good pony. Then again, the prime cost of ponies is not only infinitely less, but they can be kept in condition at a much less expense than a horse: their constitutions are twenty times as hardy; and if your stud consisted only of them, you would never be called upon to pay a farrier's little account. But the pony not only shines as a hack for the saddle; in harness he is both useful and ornamental. According to my notions of good taste, there is no turn-out of any nature or kind so pretty as a pair of handsome ponies and a single-bodied wicker carriage. Perhaps I shall be told, in these economic days, that it will not do on account of the expense, as two horses are dearer than one. That position is an erroneous one; for it is by no means an easy task to meet with a good machiner fit for a four-wheeled carriage, well broken, sound, fresh, and handsome, for fifty pounds. I could undertake for that money to buy a pair of ponies, young, handsome, and well-broken; and I might almost add, harness into the bargain. Then, as to the keep; two ponies of thirteen hands in height, can be kept well on the same food that is required by one large horse in hard work. They will give an air and style to a vehicle, which, with one horse, would look shabby and commonplace; and, moreover, will do more work, and go with more ease to themselves, and therefore, of course, more pleasant to the driver."

THE LADY'S HORSE.

Much care seems in general to be used in the selection of ladies' horses; and ladies themselves seem to be sufficiently attentive to the necessary accomplishment of horsemanship. This is evident from the comparatively few accidents which happen to them when riding.
THE COACH-HORSE.]  THE HORSE, AND [THE COACH-HORSE.

This delightful exercise is now very fashionable, and we feel assured that it is an exercise which combines health with pleasure to the riders, whilst it exhibits both the elegance and the grace of the fair horsewomen in a most marked degree.

For elegance, a lady's pad should have a considerable show of blood, and should seldom exceed fifteen hands in height. The pace should not be rough; and an easy slow trot, the pace of health, is a valuable qualification. The canter is of the chief consequence, and it should be made naturally and handsomely, the neck kept gracefully curved, the mouth having pleasant feeling. Such as have these qualifications are natural canterers, and will last at it, and, at the proper signal, will drop into the trot or walk, without roughness, boggling, or changing of legs. But the first and grand consideration is going safely; for a horse deficient in this respect, is, perhaps, always most liable to fall in his canter. The most graceful canterers may be observed to lead generally with the off-leg; but no doubt there is such an error as a horse, both in his canter and gallop, going with the wrong leg first, to the considerable unceasiness of the rider. This is most felt upon worn and battered brutes, which change their legs to procure a momentary ease.

THE COACH-HORSE.

Before entering upon a description of our carriage stock of horses, we will take a glance at the past, and briefly trace the history of the use of carriages in this country, and recount some feats of pedestrianism, which, previous to the making of roads, necessarily occurred as a means of communication between one locality and another. It is even within our own recollection, when, in Scotland, the half-silly beggar or gaberlunzie, was employed to carry letters and messages over ten miles of country, from one friend to another; and our ancestors, instead of communicating by post, were obliged to use running footmen, whose extraordinary performances were sufficiently rapid even to raise astonishment. In making a comparison between the former modes of travelling and the present, we feel a glow of satisfaction at the immense improvement which has taken place, and which almost seems to realise the expression that time is left to pant after us. The invention of the steam-engine has proved of the utmost importance. The mechanical genius of England has adapted it to carry a ship over the bosom of the Atlantic, with almost as much safety and certainty as the Locomotive whirs her train over the well-laid rail. By reducing space within a comparatively limited period of time, steam has become a great means of civilisation. It has connected the metropolis of the empire with the smallest of the British Isles; is the most rapid conductor of commerce; and is continually adding to our comforts, by, as it were, bringing "the ends of the earth together." In fact, fifty years ago, men, the most advanced in knowledge, and the most sanguine in the expectation of realising improvements, would be overwhelmed with astonishment at the immense stride the arts and sciences have taken in so short a time.

"In by-gone days, in Scotland," says Chambers, "they had a class of officials called running footmen, of whose pedestrian powers many surprising examples are noticed by tradition. For instance, in the Duke of Lauderdale's house, at Thirlestane, near Lauder, on the table-cloth being, one morning, laid for a large dinner party, it was discovered that there was a deficiency of silver spoons. Instantly, the footman was sent off to the duke's other seat of Lethington, near Haddington, full seventeen miles off, and across hills and moors, for a supply of the necessary articles. He returned with a bundle of spoons in time for dinner."

Again, at Hume Castle, in Berwickshire, the Earl of Home had one night given his footman a commission to proceed to Edinburgh, thirty-five miles off, in order to deliver a message of high political consequence. Next morning early, when his lordship entered the hall, he saw the man sleeping on a bench; and, conceiving that he had neglected his duty, was about to commit some rash act, when the poor fellow awoke, and informed Lord Home that his commission had been executed; and that, having returned before his lordship was stirring, he had only taken leave to rest himself a little. The earl, equally astonished and gratified by the activity of his faithful vassal, rewarded him with a little piece of ground, which, to this day, bears the name of the post rig—a term equi
valent to the postman’s field, and an unquestionable proof, as all the villagers at Hume devoutly believe, of the truth of the anecdote. The custom of keeping a running footman did not cease amongst noble families in Scotland till the middle of the last century.

The Earl of March, father to the Duke of Queensberry, and who lived at Niddpath Castle, near Peebles, had one named John Mann, who used to run in front of the carriage, with a long staff. In the head of the staff there was a recess for a hard-boiled egg, such being the only food taken by Mann during a long journey.

Next to the pedestrian feats of our forefathers, were their equestrian performances. The pedestrian was almost independent of roads; and hence the amazing rapidity of his feats. The rider was not just so independent; but still a rough way was of less consequence to him than to a wheeled vehicle. Hence it arises that some journeys performed on horseback, in former times, are not much less wonderful than the above examples of rapid pedestrianism.

Some horsemen of the present day would think it no mean feat, we suspect, to perform, on horseback, one hundred miles a day; yet this appears insignificant, compared with the account of the rapid travelling of the messenger who conveyed to Edinburgh the tidings of the death of “Good Queen Bess.”

Queen Elizabeth died at one o’clock on the morning of Thursday, the 24th of March, 1603. Between nine and ten, Sir Robert Carey left London, after having been up all night, commissioned to communicate the intelligence to her successor James, at Edinburgh. That night he rode to Doncaster, a hundred and fifty-five miles. Next night he reached Witherington, near Morpeth. Early on Saturday morning he proceeded by Norham, across the Border; and, that evening, at no late hour, kneeled beside the king’s bed at Holyrood, and saluted him as King of England, France, and Ireland. He had thus travelled four hundred miles in three days, resting during the two intermediate nights. But it must not be supposed that speed like this was attained on all occasions.

When we consider the state of the roads at the period at which this performance took place, it cannot be otherwise viewed than as somewhat extraordinary.

At the commencement of the religious troubles, which happened in the reign of Charles I., when matters of the utmost importance were debated between the king and his northern subjects, it uniformly appears that a communication from Edinburgh to London, however pressing might be the occasion, was not answered in less than a fortnight. The crowds of nobles, clergymen, gentlemen, and burghers, who, at that time, assembled in Edinburgh, to concert measures for opposing the designs of the court, always returned to their homes after dispatching a message to King Charles, and assembled again a fortnight after, in order to receive the reply, and to take such measures as might be called for. Even till the last century was pretty far advanced, the ordinary riding-post between London and Edinburgh, regularly took a week to the journey.

In consequence of the inattention of our ancestors to roads, and the wretched state in which these were usually kept, it was long before coaching, of any kind, came much into fashion. Though wheeled vehicles of various sorts were in use among the ancients, the close carriage or coach is of modern invention. The word coach is Hungarian; and the vehicle itself is supposed to have originated in Hungary. Germany certainly appears to have taken the precedence of the nations of Western Europe in using coaches. They were introduced thence into England some time in the 16th century; but were, after all, so little in vogue throughout the whole reign of Elizabeth, that there is no trace of her having ever used one. Wheel-carriages, however, having some resemblance to chariots, such as were used by the ancients, were brought into fashion in the time of Richard II.; for we find that “he rode from the Tower of London to the Miles End, with him his mother, because she was sick and weak, in a whirli-cote.” This vehicle was little better than a litter put upon wheels. In the reign of Elizabeth we find it mentioned in Stone’s Survey, “That divers great ladies made them coaches, and rode in them up and down the countries, to the great admiration of all the beholders.”

Lord Grey de Wilton, who died in 1593,
introduced a coach into Ireland, the first ever used in that country. One was introduced into Scotland, we rather think from France, about the year 1671. It belonged to the famous Secretary Maitland, of Lethington, who, during the civil war between the adherents of Mary and those of her son James, made a journey in that vehicle from Edinburgh Castle, which he was holding out for the queen, to Niddry in West Lothian, for the purpose of holding a consultation with some others of her friends; the first time, it is believed, that a close carriage was ever used in Scotland.

Fynes Morison, who wrote in the year 1617, speaks of coaches as recently introduced, and still rare in Scotland. For a long time, these conveniences were only used by old people, who could not well bear riding. The young and active despised them, as tending to effeminacy, and as not being so quick of movement as the horse.

The Duke of Buckingham, in 1619, first used a coach with six horses; a piece of pomp which the Duke of Northumberland thought proper to ridicule by setting up one with eight. Charles I. was the first British sovereign who had a state carriage. Although Henry IV. was killed in a coach—the only one, by the way, he possessed—his ordinary manner of appearing in the streets of Paris was on horseback, with a large cloak strapped on behind, to be used in case of rain.

In Scotland, previous to the time of the civil war, coaches were only used by persons high in the state. When the Earl of Roxburgh, an aged minister, was endeavouring to appease the Covenanters, in 1637, he was pulled from his coach in the High-street of Edinburgh, and maltreated.

Taylor, the Water-poet, complains, in the reign of Charles I., that large retinues of men were now given up by the great, since they had begun to use coaches.

Till 1564, the only mode of travelling, equivalent to that by stage-coaches and locomotive carriages in the present day, was by the strings of horses led by the carriers. It is these caravans that Falstaff and his friends are described by Shakespeare as attacking at Gadshill.

About the year just mentioned, the long waggon for goods and passengers came into use.

Stage-coaches originated less than a century later, and were for a long time confined to the great lines of road throughout England; and, till 1678, there were none for distances to which the term stages could be applied. The journey from London to Oxford, in the reign of Charles II., required two days, the space being fifty-eight miles. That to Exeter, one hundred and sixty-eight miles and a quarter, required four days.

In 1703, when Prince George of Denmark went from Windsor to Petworth, to meet Charles III. of Spain, the distance being about forty miles, he required fourteen hours for the journey, the last nine miles taking six. The person who records this fact, says that the long time was the more surprising, as, except when overturned, or when stuck fast in the mire, his royal highness made no stop during the journey.

In 1742, stage-coaches must have been more numerous in England than in Charles II.'s time; but it does not appear that they moved any faster. The journey from London to Birmingham, one hundred and sixteen miles, then occupied nearly three days.

The rate of coach-travelling, previous to the country being intersected with railroads, excited almost as much wonder among ourselves as it did among foreigners. The horses were then very hard wrought; for the art of road-making had not attained its present state of excellence, and, in wet weather, some of the coaches might be half-axle deep or more.

"When I was a school-boy," says a writer, giving a description of the road between London and Parkgate—the principal place where passengers landed from Dublin, before Holyhead became the regular station for the Dublin packets—"Parkgate, in Cheshire, was the port whence the Dublin packets sailed: there were a few at Holyhead; but there all the principal intercourse between the countries was effected. At that time, probably not one craft of any description passed in a month between Dublin and Liverpool. Upon the arrival of a packet at Parkgate, the passengers made their way, as they best could, to Chester, diverging thence to the several places of their destination. I believe there might be a stage of some kind or other, that undertook to deposit people within some limited time in London.
plying for public hire; but the manner of accomplishing the journey was most usually by means of post-coaches. These carriages were supplied by a person of the name of Paul, of the White Lion, who was celebrated at that period all over England for the magnificence of his stud. With him it was a hobby, and must have been a very expensive one. He kept no colour but greys, and of these, he had always from thirty to forty pairs in his stables. I can well remember what splendid cattle they were—his boys wearing black velvet caps, gold bands and tassels, and yellow silk jackets. He built his own carriages, dark brown, lined with scarlet morocco—doing the whole thing upon a grand scale.

A party of six, with one or two servants, would contract with Paul for a set down in London. He sent with them one of his own carriages, with its team of greys, and postillions: they accomplished the stages as arranged every day—probably of five-and-twenty miles each—and at the end of eight or nine days found themselves in the metropolis. With this fashion of travelling commenced my experience of the road; having made my first visit to Babylon the Great through the agency of one of these long jobs. At a later date I can call to mind, on an occasion of being sent for home in the Midsummer holidays, sticking fast in the middle of the turnpike-road between Whitechurch and Malpas—the latter certainly no misnomer. This antecedent of M'Adam was a desert of red sand, quartered by cart-wheels to the depth of two or three feet; and as the phantom in which I made my journey ran upon wheels of about half the diameter of those by which the ruts had been formed, of course we were let in up to the axles, where we were anchored. This took place in the nineteenth century!"

Long before the commencement of the present century, however, many of the leading lines from the metropolis, for a circle of from twenty to fifty miles around it, were far advanced towards their present excellence; but where a journey of two or three hundred miles was to be performed, it went so small a way in the matter of expedition, that the first sixth-part of it could be accomplished at eight miles an hour, where the remainder could with difficulty be done at a better speed than four.

When the use of carriages first began to supersede the old method of transporting men and merchandise upon horseback, it became absolutely necessary to devise some plan for forming a solid surface upon the bridge-ways of sand, which offered as little support to a wheel as a fallow to the coulter of a plough. Hence arose the system of paving the centre of the turnpike-roads, so generally adopted in most of the midland counties, and of which many specimens are still in existence, more particularly in Cheshire and Lancashire. With the heavy waggons, and their slow pace, while the great reduction in the draught upon this pavement effected a vast saving in the horses, the roughness of the surface was felt as no inconvenience. The gentry, in their coaches suspended from flexible C springs, passed smoothly over them; and, as it was almost the universal fashion to drive from the saddle, accompanied by outriders, the servants also escaped dislocation. But there was a class of devoted wretches for whom no such good luck was found, and who, in an honest effort to procure their daily bread, underwent the agonies of an earthly purgatory without any parallel in a Christian land. When Mr. Palmer invented mail-coaches, as might be expected, he committed a few small oversights; among these were the boxes of the coachmen, which were without springs, and were constructed upon the common principle. The consequence was, that the seats upon which they were destined to perform their vocations, were pieces of pine, or other obdurate plank, supported upon standards springing from the beds of the fore-axles. These "devil's sedans" were covered with a tanned bull's hide, to which, as a material for sitting on, granite is as an air cushion. An old sufferer, who for the last ten years of his life drove between Chester and Birkenhead, was on the Holyhead mail from Chester to Stafford in those hard times for draymen. For better than five-and-thirty years this martyr was a most communicative coachman, and, withal, had an ambition for saying smart things. On one occasion, when asked how his constitution could have supported such inhuman exercise, and whether it had not proved fatal to men less robust than he was? "Why, sir," he replied, "it was well enough when once we got used to
it: but I assure you the case-hardening was no joke: some died under the operation, and some did not; but there never was a man who tried it that it did not make him think of his latter end."

The epoch from which we may date the rapid advance in improvement as regards every department of the road, is coeval with the system of remodelling our highways upon the plan of Mr. M'Adam. That the scheme of road-making which bears the name of that gentleman was not of his invention, all who have travelled in Scotland and Ireland must have known. Still we are indebted to him for its introduction into this country, and for many judicious innovations by which he brought it to its present perfection. As the facilities for locomotion improved, so did the appliances to aid it.

The call for increased speed upon the commercial roads was afterwards answered on the Birmingham line by the appearance of three "Tally-ho's," distinguished as the "Patent," the "Independent," and the "Eclipse." Looking back to the time they were at work—their chronometrical regularity for half a score years—their pace, and the style in which they were worked through the country, and not at the ends alone, we shall hardly find anything in the mail-coach line altogether more complete than they were. Awful forebodings attended their starting: their speed was pronounced suicidal, and the waste of human life that was to result from it fearful to contemplate. But these speculations all proved vain. The only fatal accident we recollect occurring to any of them, was the death of poor Peck, the guard, who was killed by a fall off his coach while it was standing still.

In the way of fast-work, however, combined with the fashion in which it was done, certainly the pas must be given to the coaches which were put on the Brighton road by Mr. Israel Alexander. Of these there was but one opinion expressed by such as possessed experience in the coaching business, coupled with a wonder, how, by having all England to choose from, it was possible to get together such a lot of horses. On this road the public found elegance combined with speed. Taken all in all, Alexander's "Criterion," with a certain then noble marquis for dragsman, was perhaps the most correct specimen of a stage-coach that has ever appeared; but a vast deal of money was sacrificed during the short reign that this concern kept its place in the public eye.

It is now time to speak of the carriage horse.

The Cleveland's, and the powerful blood-like carriage stock, bred in Yorkshire, and other northern counties, came from the best of the Norman mares, crossed by the Arab only, the Persian blood being considered less likely to throw stock combining symmetry and substance. In his magnificent work on The Illustrations of the breeds of the Domestic Animals of the British Islands, Professor Low says, in reference to the Cleveland Bay, that "it is the progressive mixture of the blood horses of higher breeding with those of the common race, that has produced the variety of coach-horse usually termed the Cleveland Bay; so called from its colour and the fertile district of that name in the North Riding of Yorkshire, on the banks of the Tees. About the middle of the last century, this district became known for the breeding of a superior class of powerful horses, which, with the gradual disuse of the heavy old coach-horse, became in request for coaches, chariots, and similar carriages. The breed, however, is not confined to Cleveland, but is cultivated through all the great breeding districts of this part of England. It has been formed by the progressive mixture of the blood of the race-horse with the original breeds of the country. To rear this class of horses, the same principles of breeding should be applied as to the rearing of the race-horse himself. A class of mares, as well as stallions, should also be used, having the properties sought for. The district of Cleveland owes its superiority in the production of this beautiful race of horses to the possession of a definite breed, formed not by accidental mixture, but by continued cultivation. * * * * Although the Cleveland Bay appears to unite the blood of the finer with that of the larger horses of the country, to combine action with strength; yet many have sought a further infusion of blood of the finer, with that of the larger horses of the country to combine action with strength; and others have sought a still further infusion of blood nearer to the race-horse. They are accordingly crossed by hunters, or
thorough-bred horses, and thus another variety of coach-horse is produced, of lighter form and higher breeding; and many of the superior Cleveland curricle and four-in-hand horses are now nearly thorough-bred. The bay colour is in the most general estimation, but the grey are not unfrequently used."

The principal points to be looked at in the coach-horse were very great, often arising out of the competition of different proprietors; but these are now much diminished. A more generally enlightened sentiment of humanity pervades the country in reference to the brute creation; still, in the metropolis, instances of cruelty may not unfrequently be witnessed towards the over-worked horses of the omnibus and cab.

The former kind of vehicle, when first used in London, had usually three horses; but now it has generally only two. These trot and stagger up Holborn-hill, Blackfriars-bridge, and other metropolitan hills, with little allowance made for their acclivity, thus punishing the poor animals, and distressing their wind; when perhaps only the difference of five or ten minutes' delay in the journey, might enable the horses to perform it with comparative ease.

The French say, "England is a hell for horses;" but qualify the censure by a compliment that "England is a paradise for women." But however the complimentary portion of this sentence may be taken, the censure as respects our treatment of the horse, remains in all its severity.

THE CAVALRY HORSE.

In the breeding of cavalry horses, a different proportion of blood is necessary, according to the kind of service for which they are intended. Some of those for the lighter troops have more blood in them than others, and the household troops are from half to three-fourths bred. Formerly the cavalry horse was large and heavy; and, notwithstanding the grand and imposing action which he exhibited, with the beautiful style of going to which he was trained, he was "found wanting" when brought into active service. Yet our heavy household troops were found quite equal to the task of repelling the formidable charge of the cuirassiers at Waterloo. In a national point of view, there are few objects to which the eye of government ought to be more vigilantly directed, than to the improvement of our cavalry horses, or to the due proportioning of their capacity to the duties they have to perform. "If from the habit of running short distances," says the author of The Horse, "and at the very early ages of one and two years, with light weights, there is a deterioration in the strength and stoutness of our thorough-bred horses, they will become every year less and less fitted for getting stock sufficiently hardy and powerful to do credit to the courage and discipline of our cavalry."

THE CART OR DRAUGHT HORSE.

The cart breed was the cross between the Norman stallions and the largest of the Flanders mares, a race substituted in latter years for the pack-horse—bred probably from our own breed and Norman horses—when the improvements in roads enabled the adoption of wheel-carriages for the transit of merchandise, to supersede the conveyance by back loads. Thus the aboriginal blood—impoverished by an uninterrupted course of breeding in-and-in—by the introduction of fresh seed, became renovated and invigorated; the common consequence of such change whether in animal or vegetable life.

It speedily became obvious to all who were engaged in breeding cattle of every description, that vast advantages resulted from the change of blood. Hence arose the practice of hiring the males of various kinds from distant districts for the season. It is to this practice, as much as the improved methods of treatment, that we owe the excellence of every species of our live stock. Perhaps, it is hardly necessary to observe, that to the difference of soil, is to be attributed such variation in the latter breeds, as have now settled into distinct classes.

Cleveland horses of the heavy sort, have been known to carry upwards of seven hundred pounds, sixty miles in twenty-four hours, four times a week.

The Suffolk Punch, a horse of a slower pace, is the produce of the Norman stallion and
THE HORSE, AND

the Suffolk cart mare; but the true Suffolk, like the true Cleveland, is, now, nearly extinct. The Punch takes his name from the round punchiness of his own form, and is a valuable animal, although degenerated. The Suffolk was wont to be crossed with some of our hunters, and the Duke of Richmond got many excellent carriage horses from this union.

The Clydesdale is another excellent breed of draught horses, especially adapted for the agricultural purposes of a hilly country. It is chiefly bred in the Vale of the Clyde in Scotland, whence it derives its name. One of the dukes of Hamilton originated the Clydesdale by crossing the Lanark mare with the Flanders stallion. Most of the southern parts of Scotland are supplied with the Clydesdale from this district; and he has found his way even into some of the southern counties of England. Speaking of his appearance and qualities, Mr. Low says, that "the Clydesdale horse, as he is now bred, is usually sixteen hands high. The prevailing colour is black; but the brown or bay is common, and is continually gaining upon the other, and the grey is not unfrequently produced. He is longer in the body than the English black horse, and less weighty, compact, and muscular, but he steps out more fully, and has a more useful action for ordinary labour. He draws steadily, and is usually free from vice. The long stride, characteristic of the breed, is partly the result of conformation, and partly of habit and training; but however produced, it adds greatly to the usefulness of the horse, both on the road and in the fields. No such loads are known to be drawn, at the same pace, by any horses in the kingdom, as in the single-horse carts of carriers and others in the west of Scotland. Although they are inferior in weight and physical strength to the black horse, and, in figure and strong action, to the better class of the draught horses of Northumberland and Durham, yet they possess properties which render them exceedingly valuable for all ordinary purposes. On the road they perform tasks that can scarcely be surpassed; and in the fields they are found steady, docile, and safe."

The heavy black horses, such as we see in the brewers' carts of London, are bred principally in the midland counties from Staffordshire to Lincolnshire. They are majestic-looking animals; and as they have great loads to draw, they require to have great weight themselves, so as not to be shaken in the performance of their duties. All our heavy draught horses, and some even of the lighter sorts, have recently been much crossed by the Flanders breed. This has improved them by raising the foro-hand, flattening and deepening the legs, and giving them greater activity.

CHAPTER V.

ECONOMY OF THE STABLE, AND GENERAL MANAGEMENT OF THE HORSE.

Sanitary improvements in all that relates to the well-being and happiness of the inhabitants of our larger towns and cities, have, for a number of years, occupied the attention of philanthropists and medical men; and whilst the dwellings of the human have been gradually undergoing a change for the better, we are happy to say that some of those of the equine species have been receiving attention. This, however has not been so general as it is hoped it will yet become. We have still to lament, with Mr. Stewart, in his admirable work on Stable Economy, that "stable architects have not much to boast of. Their sole ideas are limited to shelter and confinement. If the weather be kept out, and the horse be kept in, their objects are attained. If light and air be demanded, the doorway will admit them. If the horse has room to stand, it matters little, though he have none to lie; and if you can get him into the stable, what consideration is it, though his loins be
ORNAMENTAL STALL DIVISION

IMPROVED STABLE FITTINGS BY MESSRS. GEORGE SMITH & CO. GLASGOW
strained, or his haunch bruised in getting out of it."

Loftiness is one of the most desirable attributes of a stable, and due regard ought to be paid to its proper ventilation, for horses as well as men are poisoned by breathing in an impure atmosphere. We will, therefore, here consider some of the most essential requisites of a healthy stable.

AIR.

Mr. Clarke, of Edinburgh, was the first to advocate the use of well-ventilated stables; and after him, Professor Coleman, of the Veterinary College, established them in the quarters of the cavalry troops. Their advantages were soon made apparent in the discontinuance of diseases that formerly dismounted whole troops of soldiers, and in the consequent pecuniary saving which they effected to the government.

Chemical science has now ascertained, with the utmost exactitude, the atmospheric conditions required for the preservation, in a healthy state, of the animal functions, and Lavoisier adduces a striking instance of the sensible malaria of an atmosphere breathed over and over again by a number of animals confined within a limited space. He shows that when the air out of doors contained 27 parts of oxygen, and 73 of nitrogen = 100, the air in the lowest ward of the central hospital at Paris, contained 25 parts of oxygen, 71 nitrogen, and four of fixed air = 100. Before the play in the theatre of the Tuileries, the air was 27 parts oxygen, 73 nitrogen; towards the termination of the performance, it was 21 parts oxygen, 76 1/2 nitrogen, and 2 1/2 fixed air. Thus, in the hospital, the oxygen, or living principle, had decreased as twenty-one to twenty-seven, or nearly one-fourth. This proves the necessity of having a well-aired stable for the horse, as well as a well-aired house for oneself to live in. "We have frequently observed," says Mr. Karkeeke, "a kind of balance between the respiration and the digestion; and he who is a careful observer of horses in a healthy, as well as in a diseased state, must have noticed that there is a certain balance between the quantity of vital air received into the lungs, and the quantity of food which can be digested in the stomach."

Again, "the blood requires pure air as its food; the first effect of the air is to remove the carbonic acid, which the venous blood takes up in the circulation; and when this is effected, the properties of the blood become instantly changed. In the commencement of this process, the air is the active agent, and removes the carbonic acid from the circulation; but when this is effected, the blood then becomes the acting power, and attracts a portion of the atmosphere. The pure air, or at least it ought to be so, then occupies the place of the carbonic acid which is just removed."

These facts are sufficient to show the necessity of having the stable well-ventilated. Indeed, the principal cause of mange, bad eyes, glands, grease, swelled legs, and inflamed lungs, witnessed in many horses, is on account of the smallness, and the ill-ventilated state of their stables. A stable, therefore, with a loft over it, should never be less than twelve feet high; and if it is to contain three horses, it should not be less than twenty, or twenty-two feet long, and fourteen wide. An aperture should be made near the top of the wall opposite the door, to allow the fetid or foul air to escape; and to admit the fresh and wholesome air, other two holes, of the same size, should be made on each side of the door, at about the height of a foot from the ground. Stables, however, are not, at all times, built in situations where the convenience of a good ventilation can be readily obtained. Where this is the case, the following remarks by Mr. Brett, veterinary surgeon of the 12th Lancers, when in the Manchester barracks, supply some hints.

"Suppose a stable to be blocked up by other buildings on all sides except at its two ends. In that case I propose to have a large wooden tunnel, two feet square, running the whole length of the stable under the mangers; and if it should be a double stable, one tunnel under each row of mangers. These conduits are to come through the end walls of the stable, and to be open at both ends on the outside, for the purpose of admitting a thorough draught or body of air through them. This main stream of air is to be equally dispersed about the stable, by means of perpendicular wooden shoots, or chimneys, six inches square, emanating from this main tunnel, one at the
head of each stall partition. They should be seven or eight feet long, so as to avoid a draught on the horse's eyes, and open at their tops like chimney-tops, and should stand out two feet from the wall. The rarerfied state of the air in the stable, will cause a constant flow of cool air through this main tunnel, and up these chimneys; and will equalise the temperature of the stable, and entirely obviate the draught of wind that blows in at the horizontal holes in the walls of our stables as at present ventilated. These perpendicular chimneys may have one or two other apertures in them besides the one at their tops, at different heights, that may be opened or closed at pleasure, to admit air by means of a door with a hinge and button, opening on that side next the wall, whereby a direct current of air upon the horse will be averted. If these air passages should not be thought sufficient, other horizontal tunnels branching from the main one, might run from it at right angles under each stall partition, and terminate in a perpendicular wooden chimney, six feet high at each heel-post."

The window of the stable should be at the south-east end, and the door at the opposite end. The window should be as high as the ceiling will admit of, and in size proportionate to that of the stable. In a stable of twelve feet high, it need not come down more than four feet, and will then be eight feet from the ground, and out of the way of being broken. The frame of the window should be movable upon a pivot in the centre, and opened by means of a cord running over a pulley in the ceiling, and fastened by means of another cord.

With a window of this kind, in a stable with three or four horses, no other ventilation will be required. A person never need be solicitous about finding openings for the air to enter, when there is sufficient room above, and means for it to escape.

It is unnecessary to enlarge on this branch of our subject, as enough has been said to show the absolute necessity of keeping up a supply of pure air in the stable. That its temperature may be known, no gentleman's stable should be without a thermometer, which should never be allowed to sink below forty or fifty degrees in the winter, or ascend above seventy in the summer.

**LIGHT.**

This is another of the most important elements in a well-constructed stable.

Where much light is admitted, the walls of a stable should not be white, but of a stucco, or lead colour, and better if painted; for then they may always be washed clean with soap and water, as well as the stalls, rack, and manger. This should be done once in two or three weeks, or a month at furthest. If the walls are boarded up to the height of about five feet, and this, as well as the stalls, painted of a light wainscot colour, it will look extremely neat, and the under part of the wall will be kept drier, and appear more comfortable. A stable should be lighted by means of an Argand lamp, suspended from the ceiling, and movable. This will give a far better light, is cheaper, and more secure than any other contrivance whatever, except gas-light; and, if properly trimmed, will burn without a particle of smoke. As a general rule, dark stables are uncleanly; and they are the frequent cause of making the horse start, and of giving him sore eyes, when he emerges from them. No stable, however, should have too strong a light, as, like the bed-room of his master, it is a place of rest. The proper quantity, then, should be regulated, which a little observation will very soon enable every possessor of a horse to do.

**THE FLOOR.**

A stable, when properly paved, and kept moderately clean, requires only a shallow wide gutter, twelve inches wide, and one inch deep. The best floor for a stable, by far, is hard brick; and next to that, limestone, not less than one foot square. The floor of the stall should never incline more than one inch in a yard; and the inclination should be continued back to the gutter only. "If the reader," says Mr. Lawrence, "will stand for a few minutes with his toes higher than his heels, the pain he will feel in the calves of his legs will soon convince him of the truth of this remark, 'that too great a slope strains the back sinews of the leg.' Hence, when a horse is not eating, he always endeavours to find his level, either by standing across his stall, or else as far back as his halter will permit, so that his hind legs meet the ascent on the other
side of the channel." It is also remarked by Mr. Blaine, that—

"In the stables of dealers in carriage horses, an ascent in the standings of nearly two inches in the yard is sometimes made, to give a greater appearance of height to the yet unfurnished four-year-old horses, which are thus often passed upon the unwary as horses of five years old. Is no strain put upon their legs? Our experience, which has been somewhat extensive in these matters, convinces us that the inequalities in the standings of horses is a fertile source of contraction of the feet. What but the pain and inconvenience which follow an uneven position, occasions horses, when not feeding, to be so frequently found standing across instead of lengthways in their stalls? How frequently, also, will the horse, boxed in a stall, be found with his croup turned towards the manger? To avert these evils, and yet to prevent the retention of the urine, the smallest possible slope should be allowed, which should proceed uniformly to the bottom of the stall.

A central grating, with a cesspool, is an imperfect remedy for the evil; for there must still be a general inequality of surface to carry the urine to the centre. It is further injurious by retaining the urine we wish to avoid; and, moreover, it promotes a draught of cold air from without, if it be so constructed as to carry the urine out of the doors. It may, also, be remarked, that a central cesspool is utterly useless for mares. It is, therefore, the best plan to furnish each stall with a grating placed over a small trapped drain, at the foot of each stall, which will carry off both the urine and the washings into one general cesspool out of doors, and from which, being stopped by the trap, nothing offensive can pass up through the gratings."

THE STALL, THE MANGER, AND THE RACK.

The width of a stall should not be less than six feet, clear. But when there is sufficient room, it is a much better plan to allow each horse a space of ten or twelve feet, where he may be loose, and exercise himself a little. This will be an effectual means of avoiding swollen heels, and a great relief to animals that are worked hard.

With respect to the rack and manger—the manger should never be less than eighteen inches deep; eighteen inches from the front to the back part; and two feet in length.

In post and waggon stables, where the stall is made for a pair of horses, the manger will be placed at each end, and the rack in the centre. It will then be necessary to put one bar in the centre of the rack, on the top, from the front to the back part, to prevent the horse from throwing out the hay with his nose.

The rack may have staves in the front, like a common rack; but it is better to have it partly closed in front. The back part of the rack should be an inclined plane, made of wood; should be gradually sloped towards the front, and should terminate about two feet down. Such a rack will hold more hay than ever ought to be put before one horse. The advantages of this rack are numerous. The saving in hay that may be effected by its use is so apparent, that it need not be dwelt upon.

A great saving also may be made in oats, by so fastening the horse's head during the time of feeding, that he cannot throw any of them out of the manger. If a horse is allowed a peck of oats a day, and has, as he may have, one-eighth part of them thus saved, it will amount to nearly a peck in a week. There must not, however, be a diminution in his allowance on this account. A horse should have one peck of oats in twenty-four hours; but then he should not have more than from eight to twelve pounds of the best hay in that time, given at four, or three times at least.

This kind of rack and manger, from being boarded up in front, will effectually prevent the litter from being kept constantly under the horse's head and eyes, by which he is compelled to breathe the vapours which arise from it. It will also prevent him from getting his head under the manger, as sometimes happens, by which means, not unfrequently the poll-evil is produced.

The length of the halter should be only four feet from the head-stall to the ring, through which it passes. This will admit of the horse lying down with ease, which is all that is required.

The ring should be placed close to that side where the manger is, and not in the centre of the stall. The sides of the stalls should be sufficiently high and deep to prevent their occupants from biting or kicking each other.
LITTER.

Instead of having a large corn-chest in the stable, a handsome seat might be made at the back part of it, extending as far as may be necessary. In this there may be partitions to separate the beans or the bran; and places might be made to rest the arms upon, so that a gentleman might sit down comfortably, and have the pleasure of seeing his horses taken care of. A comfortable stable will be found conducive to the health of the horses, and will be an inducement to the groom to attend to every little circumstance which may contribute to cleanliness. He will not allow the smallest bit of dung to remain swept up at one end, or into a corner, as it commonly is. The pails should be kept outside, and not standing about the stable, as they usually are. If it be necessary to take off the chill from his drink, it is much better, and more easily done, by the addition of a little hot water, than by suffering it to stand in the stable: and while the horses are at exercise, the litter should be all turned out to dry, and the brick floor well washed, or swept out. Some litter should always be allowed for a horse to stale upon, and this should be swept away as often as it is necessary, to prevent offensive smells. Litter dried during the day, will serve again as well as fresh straw for the bottom of the bed, and be perfectly free from smell. That which is necessary to be kept under a horse, that he may stale with comfort, and without splashing himself, is not considerable, and may be changed once a day. A great saving might be made in it, by turning it out, and drying it; and if a shed were built adjoining the stable, this could be done at all times, and the horse might be cleaned in the shed in wet weather.

Neither dogs, fowls, nor goats, should ever be permitted to enter a stable; and dung should be kept at a distance from it. Whilst speaking of these general arrangements, it may not be amiss to notice a good contrivance in cleaning horses; that is, to have two straps, one on each side of the stall, about one yard from the head of it; by these the horse may be fastened during the time he is cleaned, and he will be effectually prevented from biting the manger or the groom. He will also be kept back in the stall, which will enable the groom to clean more perfectly the front of his fore-legs, chest, and neck; and to move round him. This is better than strapping him to the rack. When the common rack and manger are preferred, the rack-staves should be straight, and brought nearly down to the manger. This may be done without the necessity of a hay-loft, and the manger may be made deep and wide, as already described.

GROOMING.

Although it is not usually the case that gentlemen, themselves, look after their own horses when they are stabled; still, we presume that many desire to have such a knowledge of the stable department, as will enable them to judge of the competency or incompetency of their grooms; for it is not the good fortune of every one to have a thoroughly professional groom, who understands his business, and who is trustworthy in all the parts he has to perform in it. There are some who undertake the duties of grooms without understanding hardly anything about a stable; and while gentlemen do not inform themselves of the necessary duties and business of this department of their establishments, they are most likely to be greatly imposed upon, or injured, through the ignorance, indolence, or artfulness of the pretenders they may have engaged. Little as may be thought of the merits of looking after a horse, it has been remarked, that not more than one in ten, upon the average, of stablemen employed in livery-stables and dealers' yards, know even the simple process of properly cleaning or dressing one, though this is the first or principal thing required of them, and nearly all they have to do. This is the case even after they have followed the occupation for years, and been industrious, pains-taking men, who did not spare their labours. Since such is the fact, it is evident that there is more art attached to this profession, than at first suggests itself to the mind.

There are certain natural qualifications which should be preferred and sought after, if they can possibly be found, in the person that has the care and management of valuable horses. Above all things he should be sober, mild, and patient in his temper, so that he is not easily provoked; for material injury has been done by passionate persons incautiously striking.
horses in a wicked manner, with whatever instrument might be in their way; sometimes the corners of the curry-comb, the broom-stick, twitch-staff, or even the stable-fork. We have heard of a groom, who, in a fit of rage whilst stopping a horse's feet, for which he had a small trowel, actually drove it into the animal's side between two of his ribs. The person who looks after horses should be industrious, and not sparing of his labour at any hour or season; for horses require much attention to make them fresh and comfortable; and if a groom is sparing of his labour, they will soon show it, as there are few kinds of work harder than grooming a horse properly. It is true, that an indolent groom may escape censure or complaints of persons not very particular or discerning; but those who are judges cannot be imposed on. The appearance and condition of the animal will discover itself, and cannot escape their notice: for when a person knows that everything is allowed to keep his horses in proper condition, and also knows when his horses are in the condition in which they ought to be, he will never be satisfied to see them otherwise.

There is no good groom that has not a pride in seeing, not only his horses, but everything in his department in the first style of condition and cleanliness. Where this disposition exists all goes well. Confidence is inspired, and a trust, which otherwise might be withheld, freely and voluntarily reposed in him, regarding all that appertains to his system of management. With these natural qualifications there are practicable requirements, which, with attention, observation, and an apt capacity, may easily be acquired.

The grand aim of a groom ought to be to put his horses in what is called condition: let us, therefore, consider what is meant by condition. This word is variously applied to the state of the horse, though widely different from what is here implied. For instance, we say, a horse is in condition for sale; that implies he is in flesh, his legs clean and fresh, his coat decently fine, and perfectly sound; a horse may be all this, but not in condition for work. Another horse is said to be in good working condition. Such might be said of a post-horse, that is bare of flesh, his joints enlarged, and his legs puffed with windgalls; yet this horse is capable of doing much work; and his being worked more than is requisite to keep him in condition, has put him out of condition.

Condition, therefore, without an expletive, implies that perfect state of body and limbs in which the whole system is in the most vigorous state, and capable of the greatest exertion, if required. This cannot be either obtained or preserved without strictly adhering to three things; viz., proper food, proper grooming, and necessary exercise. Neither of these must be omitted, nor injudiciously employed; for, like medicine, properly administered, each does good, but is capable of doing much injury, if profusely taken or misapplied.

Stable hours should be kept with strict regularity. All animals appear to have a knowledge of time; and it may be observed, in many instances, that they observe the periods as correctly as those who attend them, and who, let it be remembered, have recourse to time-pieces. The horse knows his stated hours; and if he is not attended to, particularly to feed and water at the accustomed time, he will be watching and fretting with much anxiety, and oftentimes will call and ask for his food, in such a manner as those accustomed to horses cannot fail to understand. Regular and stated hours should be punctually kept, with as little variation as the season or circumstances may require—say five o'clock in summer; but as the days shorten, a later hour is admissible, unless horses are to be ready at an early hour for hunting, otherwise. In such cases, two hours, at least, before they are wanted, the stable should be visited. If this is not done, and if sufficient time is not allowed to look after things, they cannot be done as they should.

The first duty of the groom on going to stable, after throwing his eye round to see if any horses are loose, cast, or the like, is to rack and feed. The judgment in racking is to give the horse but little at a time, that he may eat it with an appetite, first clearing out his rack, &c., &c. If a horse leaves hay that is good and sweet, some cause must be assigned for it, and it must be examined into. Sometimes cats will foul the hay; and horses are very nice in their food, when not kept scanty. If the animal appear to be in health, and the hay has not been blown on by other horses, but is fresh and sweet, it may reasonably be supposed that
he is too plentifully fed, and leaving hay for the sake of oats: this should be guarded against; therefore, if hay that is good and clean in moderation, is given to him, it is better to shorten his allowance of oats, to bring his stomach to a comparatively small quantity. His morning's racking should be one quarter of his daily allowance, which, on the average, is about three pounds for his breakfast; for abundant feeding in the morning is not good. A horse cannot work agreeably to himself when over-full; and, therefore, the plan of feeding sparingly in the morning should be adopted. If you want some exertion from him, do not suppose that a full belly will make him perform it better. It is the food that he has digested, and from which he has obtained that nutriment and its consequent stimulus that is to support him in his work, and not what you cram into him at the time you want him for great exertion. A good horse, in proper condition, will not flag in twelve hours, if he is required to be at work that time, and, on a moderate computation, supposing he has carried his rider a hundred miles, without, as it is termed, drawing bit. This, however, is not to be expected from every horse; none but thorough good animals, in proper condition, can undergo such extraordinary exertion.

The quantity of hay which should be given should be well shaken, to clear it from dust and seeds; and if it is very dry, as it sometimes will be, it ought to be sprinkled with water, to make it more agreeable to the horse, when he will eat it with better appetite. Many horses, when they perceive, or instinctively suppose they are going out with the hounds, or have seen the rider come into the stable with his scarlet coat on, and in his white cords, refuse to eat their hay or oats. This, we imagine, arises from an impatient anxiety regarding the animating prospect of the chase, of which most horses are fond, but some uncommonly so; but whether they disregard their food from this feeling, or whether they refuse it, knowing they will be better able to gallop with an empty stomach, it is difficult to determine; certain it is, however, that horses never perform the worse for it; and it may be taken as not a bad prognostic, when a horse refuses his food under such circumstances. It is very common, however, for a horse to be off his food after any great exertion; and this is by no means a pleasant circumstance, especially to a true horse-man.

After having racked with hay, the next feed, as it is termed, is to serve him with oats. Here we are proceeding in the routine that is to be daily observed; for, were we to treat of things out of this regular order, young hands might be studying what they should do, and what ought to be done first; and it is no uncommon circumstance to see some, that have been in the stable employment for a considerable length of time, not know what to do first, and occasion themselves trouble and loss of time, by doing that which is not urgently required. In serving the oats, whatever is deemed a sufficient allowance for the horse, for the day, whether it may be three quarter-s or a peck, one-fourth of the quantity should now be given. As sweet and clean food is most agreeable to the animal, as well as beneficial, carefully sift the corn from dust, blow away the chaff, and pick out anything which may be deemed unfit or unpleasant. Frequently will be found among them, rat's dung and cat's dung; therefore clear the manger with a whip of hay or straw, and throw in the oats; let them be spread with the hand, to prevent the horse from taking too greedy a mouthful at a time, and swallowing them without chewing.

While the horses are eating their first feed of corn, which, it must be recollected, is to be given immediately on entering the stable in the morning, prepare the saddles and exercising briddles, that they may be ready to be taken out. These being ready, and placed on for exercise, give the horses a few go-downs of water; then, if it be an establishment of some considerable extent, give orders to the stable-boy to make fair the stable during your absence, in the following manner. If it should be a single-horse stable, this process may not be required so minutely: first, throw all the dung off the litter, clear out behind, then turn up the driest and best of the litter under the manger, and the wet and muck turn out behind; this being removed to the dung-heap, sweep clean out, then take a bucket of water, and wash the stall out well. After the water is run and swept away, take the bedding that has been put under the manger, and place it behind the horse's stall, against the wall; by doing so, all
the disagreeable smell that may probably arise from the bedding being allowed to remain under the manger, will be removed, and, in all likelihood, the horse prevented from being affected with diseases of the eyes, glands, inflamed lungs, &c., &c. This being done, take a little of the litter and shake it in the stall, for most horses stale on first coming into the stable, from exercise, and this will induce them to do so freely. Thus will the stable be free from any effluvia which arise from the dung and urine.

The stable being made clean, next commences the cleaning of the horses. This is a work that requires more knowledge and judgment than at first appears. The curry-comb is the first thing to be applied, and great attention should be paid to the proper mode of its application. Some horses require much of the curry-comb; others, none: this depends on the state the animal is in, the time of year, &c. Horses that have their coats long and full of dust, such as are just taken up from grass, or such as are come out of persons hands, that either do not know, or do not take the pains to keep their coats clean and fine, will require the free use of the curry-comb. In reference to the comb, its teeth and sharpness should be proportioned to the thickness, length, and fullness of the coat. For horses that have been kept in stable, properly groomed, and have their coats fine, thin, soft, and clean, requiring no other use of the curry-comb than merely to clean the brush, or occasionally to rub off any dung that may be on them, the teeth of the comb should be remarkably even and dull, not to scratch them.

These things being attended to, after stripping the clothes off, the curry-comb should next be used, always beginning on the near side at the hind-quarters, and using it in proportion to the length and fullness of the coat. If the coat is fast on, long, full of dust, and very filthy, it may be used freely to loosen it, or the sweat that is dried and fastened on the skin and roots of the hair, will appear like a white and saltish dust; but it is not to be expected that all the dust shall be got out at once. It must be a work of time; and to attempt it by using the curry-comb too much, the coat will be set on end, the pores of the skin will be opened, and the horse will, in conse-

quence, be very liable to take cold, which will obstruct that imperceptible perspiration which, in a healthy state, is always going on; and which, if suppressed, causes to be thrown up an ichorous discharge, which will dry into small scabs. The coat will then stare, put on a russetty appearance; be rough, and have a very disagreeable look when compared with those horses whose coats are fine and clean, such as the race-horse, or the hunter, when got into proper condition. Another thing to be observed is, that if it be during the season when the horse is changing his coat, when the hair will come off freely with the curry-comb, it is not advisable to be too free in the use of the comb for the purpose of removing the coat, but let this have its time to come off. With good feeding the end will be obtained quicker than by scratching the horse’s skin with the comb. Providence has wisely ordained that the horse’s coat, if exposed to cold, shall grow long, and if he is kept warm, it will remain short.

Proceeding to curry on the hind-quarters, for the purpose of unmatting the hair and loosening the dust, it is necessary to descend down the quarters, particularly remembering to rub off all dried dung, and taking care not to injure or scratch the horse’s legs. It is to be observed that the curry-comb is not to be used below the hock, unless some dung may be there. Whilst employed here, you must handle the comb very lightly; and with grey or white horses, stains are very troublesome to remove; but if a wet sponge is taken, and the hair well moistened where the stain is, then a knob of common stone-blue—such as is used by washerwomen—put into a piece of flannel, and rubbed well on the stains, will be able to remove them. When this is dry, it must be well brushed off.

After having carried the horse’s hind-quarters, proceed on to the back, loins, flank, belly, shoulders, arms, chest, and neck, omitting no part to which the comb can be conveniently applied. Tender places, or such as have thin hair, need not be touched, neither need the head be touched. Horses are not ticklish when they are full of the dust occasioned by the natural and imperceptible perspiration of the body; but as they become clean, and their coats short and fine, they are exceedingly
ticklish, and, therefore, it is necessary to be careful to stand in a secure place. After having curried the near side, proceed in like manner to curry the off side; but with the difference of using the left hand, which, after a while, becomes the most convenient. This done, the next proceeding is to whip off the dust raised by the curry-comb, and to rub and whisk well those places which were not proper for the comb to touch. For this purpose, a whip of some half-worn straw should be made, but a hay-band is better, which should be prepared for the purpose, by half untwisting it; loosening it thus, it will be doubled about a foot in length, and, loosely twisting it together, it will not scatter so fast, till you have made it as thick as you can grasp. If it is dry and harsh, sprinkle it with water. This will make it work pleasanter, and the dust which is intended to be removed, will adhere to it, and not fly about so much.

In whispin' the horse, begin at his head, taking the whip in the left hand for the near side, and resting the right hand on the most convenient part of the animal, to steady yourself while the whip is applied. Then change its situation, beginning first at the top of the neck, down to the shoulders, then the under part of the neck, the chest, particularly between the fore legs, down the arms, knees, and the sinews and fetlocks, taking care to rub out the dirt well from the heels, where the curry-comb cannot be brought into use. Having done this, proceed on in the order of his carcass, on the back, sides, belly, croup, and so on to his hind legs, which ought to be cleaned as carefully as the fore ones. After this, whip in the same manner his off side, only changing the whip from the left to the right hand.

Proceed next to brush the horse over, after having first cleaned the brush well with the curry-comb. Begin at the croup or rump, and well brush the body backwards and forwards, the brush being in the left hand; for the near side, work up in all parts as before, and finish at the top of the neck; then in leaving it, brush the horse the straight way of the hair, and finish at the near fetlock and heel behind. The same plan should be pursued on the off side, changing the brush to the right hand. Many stable-men attend much to those places that are most conspicuous to the eye, such as the fall of the neck, the shoulders, and hind-quarters. These parts shine the most; and they do not fail to point out these to you, and say how well they look, which may satisfy some persons, but a judge will not be deceived by external appearances. He expects the parts not immediately in view to be equally attended to.

After the brushing, which causes much of the dust to be floating about, when a part of it, in all probability, will again settle on the horse, he should be wiped all over with a linen cloth, beginning, as with the whip or brush, at the head, and so proceeding to every part. This being done, put on his clothes before finishing with his head, mane, tail, and legs, that he may not chill or take cold while you are about them.

It must be understood that we are here treating of the method to be pursued in the hackney stable, and not in the racing and hunting stable, though there is very little difference in treating the hunter and the hack, except it be in a greater addition of clothing and more dressing, the days he may be lying at rest.

The clothes being properly put on without wrinkles, perfectly smooth, and especially under the roller, loosen the horse's head, take off his stall-collar, and turn him round in the stall, to give his head and ears a complete rubbing and brushing, which is not so easily done with the stall-collar on. The head is now to be brushed over in every part, particularly at the root of the ears, and under the throat; then, with the dusting-cloth, rub and wipe him well; pull his cars through the hands, observing that they are clean and soft, and moderately cool; then comb out his mane and foretop, with a sponge or water-brush, wet the top or roots of the mane, and pass a small cloth for that purpose over it. This cloth being passed from the near side at the top of the mane, and pulled over to the off-side, will make the mane lie smooth. Next put on his stall-collar, and comb out his tail; wipe away any dirt or filth that may be remaining under the tail with a wet sponge, and after with the cloth. The feet of the animal are next to be examined, and the dung and litter picked clean out, and, if necessary, washed. Lastly, the legs are to be rubbed with a clean loose whip of straw in each hand; for which
purpose you should go down on both knees, pass the whip over the legs and tendons, then finish with passing the hands down in like manner, to feel that they are perfectly smooth, and that there are no particles of the straw or thistles, which might be among it, adhering or sticking to the hair. These rubbings will increase the circulation, and, consequently, will promote the absorption of any fluid which may be detained in those parts, and which, too frequently, occasions swelled legs; and, if neglected, the heels may crack, and produce grease, which, with a little extra trouble, may, at all times, be prevented.

The morning's business of the stable being thus completed, the horse will require nothing until noon.

Before proceeding further, we will show the reasons for feeding the hackney, which is not to be fed in the same manner as you would a hunter that has extraordinary work to do; yet a hackney should be always in a condition to be able to perform ordinary work with ease to himself and comfort to his rider.

Moderate exercise for a good hackney is about thirty or forty miles an end, without drawing bit, at the rate of from eight to ten miles an hour. This may be called ordinary work: but to gallop twenty miles, or trot sixteen in an hour, extraordinary work, which, to accomplish, requires a horse to be put through a regular mode of training.

But to return. At noon give him the like quantity of hay as in the morning, and his feed of corn; set the stable fair; that is, put the litter to rights and remove the dung. This is all that is necessary till watering-time, which is about four o'clock, when the horse should be stripped and brushed.

There are some lads who can hardly be persuaded of the necessity for this, alleging that they cleaned the animal perfectly well in the morning; that he had not been out of the stable, and that the clothing prevented dust from settling on him; therefore, they cannot conceive the necessity for it; and many others may be of the same opinion; but the imperceptible perspiration, which is always going on, occasions a scurf, the removal of which greatly refreshes the horse. Besides, stripping the cloths off, and brushing him over, greatly refreshes him, and puts the blood into a freer circulation. Wipe him down as before, finishing with rubbing his legs, which must never be omitted, combing the mane and tail, &c., then watering. If there is not a probability of the horse going out, let him have a greater quantity of water than in the morning; and if he be not greedy for water, he will not drink more than will do him good; but, if you perceive his belly getting too large, and he appears washy, he must be restricted. Set the stable fair again, and the work is done until the final doing up for the night.

At about eight o'clock finish for the night by giving him his remaining allowance of hay, which should be double what was given him in the morning, and his remaining feed of corn. Give more abundantly at night, because it will be in so forward a state of digestion in the morning, as not to oppress the wind of the horse when working. This will be a guide how you should vary it upon particular occasions, so as to have the animal in good heart and spirits, but empty, when wanted for expeditions purposes.

The last thing is making up the beds and setting all fair. In making up the beds, contrive to lay all the worst of the litter in the middle or bottom, where the horse is most likely to spoil it. In throwing down the litter which was placed behind the horse in the morning, reserve the cleanest and driest part to top the bed with, making this up high on each side, and fullest towards the hind quarters, that it may be soft and pleasant for him, whichever side he may lay on, as some horses turn frequently in the course of the night. Now throw out all dung, and sweep clean; see that all the stall-collars are secure, loose cloths taken off, and everything set fair, and the routine of the stable is finished.

EXERCISE.

Exercise is so essential to the horse, that feeding and grooming would be of little use, were it neglected, or altogether omitted. It is admitted, that great numbers of horses are killed or spoiled by being over-worked; and it may be doubted whether as many are not injured in London for want of work. In the metropolis there are several persons who keep horses, but who are so occupied with business, that they cannot ride them out oftener than
once in a week, and many don't ride them once in a month. The horses of these persons stand at livery, and they are ordered to be exercised. Men employed in livery stables, have seldom less than six or eight, and we have known some to have ten livery-horses to look after. These men, if they rub off the dung, and occasionally give them a brush over, omit exercise, not finding time for it. Gentlemen do not like to see or know that boys are permitted to ride their horses; and, without they keep grooms of their own, their horses will go short of exercise.

Consider, then, those horses that are kept in a livery-stable from week's end to week's end, in many places confined and filthy; that are sometimes moved about, which they call exercise, but which is merely a ride of, perhaps, fifty or sixty yards long, in a place made up of litter and dung, with a manure-heap at some part of it. In these cases horses literally breathe only air strongly impregnated with the evaporation of dung. Under such circumstances, it is surprising that they are so well as they are. The disorders with which they are frequently afflicted in such a condition, are principally cough, not improperly called a stable cough, also weakness in the legs, so that they often make a drop, as it is termed. Various humoral diseases, such as swelled legs, grease, farcy, and, in all probability, inflamed lungs and glanders, also, are the result. At their best, when they look plump and well to the eye, they are faint, and what is termed foggy, and unable to perform more than what would be common exercise for horses in condition.

Since, therefore, exercise and air are so beneficial, let us consider in what manner exercise should be given. This is to be regulated according to circumstances. Where animals work two or three days in the week, the resting days require no more than airing exercise, for every horse should have, at least two days in the week, such work or exercise that will give him a good sweating, which throws out, through the pores of the skin, what might lodge in the system and create diseases. It likewise frees the horse of the scurf adhering to the skin, and occasions the coat to look fine. Those days, therefore, that the horse is not wanted for work, he must be exercised for the fresh air which is bracing and strengthening to his limbs, refreshing the body, and creating an appetite. The most eligible time for this is in the early part of the day; but, in wet weather, the best opportunities that appear must be taken advantage of.

If but one horse is kept by a gentleman, he should order his groom, as soon as the stable has been cleaned out in the morning, which is while the horse is eating his first feed, to brush him over, and put on his exercising saddle and bridle. In cold weather, if it is only intended to walk him, the cloth or sheet may be kept on him under the saddle. In warm weather, however, we do not recommend this; for, though a horse's coat may be something the finer by being kept warm, yet he is certainly the more liable to take cold when he is necessarily deprived of it. The most open and airy places should be taken for exercise, during which the step of the horse should try to be improved; and, when he has only walking exercise, he should at least be walked two hours, which will be sufficient. By aiming to extend his walk, he may be greatly improved. On returning, thoroughly clean him, and give him his feed. He might be watered while out, provided it can conveniently be done. If a horse is hearty, and inclined to flesh, we would rather recommend the like exercise in the afternoon, where persons have time and convenience, than to shorten his feed for that purpose. It would be much better for the horse; but every one cannot allow his time to be so taken up, for it would be nearly equal to training, and may not be thought necessary. It is more than the generality of horses require; and many inferior-bred animals which look well to the eye, cannot, for a continuance, stand the ordinary work that a horse has in training. Such is the amazing difference of horses. If inquiry be made of many training-grooms, concerning some high-bred colt or other, why he is not brought out, they will answer "he would not stand his training;" though, perhaps, in numerous cases, training, in the present day, is screwed up to too tight a pitch.

Should the work of the horse be so moderate as not to occasion a sweat, it is beneficial, about twice a week, to give exercise strong enough to sweat him. This may be done in the pace he is mostly ridden in, that he may be practised and improved in it. If he be admired
for his trot, it would be wrong to gallop him, as such an act might unsettle him in his esteemed pace. Therefore trot him out for the space of two miles to bring him to a comfortable sweat, and walk him back. Thus his limbs are extended; his muscles made supple; and his ligaments and tendons strengthened. Inactivity debilitates, and over-exertion may sprain and weaken, but moderate exertion is good both for man and beast.

The sweating of horses occasions considerable labour to clean them; and indolent grooms, and those who have several animals to look after, avoid this part of their business as much as possible. Some would persuade us that there is no necessity for it; but reason and experience teach otherwise.

When a horse is brought in from work or exercise, if in a sweat, or wet and dirty with sloppy roads and rain, he should not be left until made completely dry, clean, and comfortable. Some horses, in good condition, will rub dry and clean in a short time; but others, with long and curly coats, and some from constitution or ill condition, are a long time before they can be made dry; hence, clipping has been introduced; but this we are decidedly opposed to, as it is to be prevented altogether by good grooming. Besides, clipt horses are apt frequently to take cold; hunters, especially, in a slack day. We have known an industrious groom to work at a horse for four hours, and not leave him until perfectly dry; and we have known others to cover them with a cloth, and leave them to dry, before they would clean them. Much depends on the habit the animal has been used to, constitution, condition, &c., whether he will take injury from being left in his wet and dirt. Those horses, however, that have been properly groomed, and have all care taken of them to keep their coats fine, and, on all occasions, made dry and comfortable, will be liable to take cold, if neglected at these times.

Some persons are fond of physicking or bleeding their horses, when there is no apparent cause or reason for it. Many grooms take upon themselves the duties of bleeding and physicking at their own discretion. It is, therefore, necessary to assign some reason, and to show when, and for what purpose, such modes are to be pursued. It is best to follow such methods as preclude the necessity of either; for, with proper feeding, exercising, and grooming, there will seldom be occasion for physic; but sloth or idleness is the parent of disease; and thus it happens with horses, when they are well fed, and have little or no work—horses not being intended to stand in a stall, and fatten like a bullock—the blood-vessels get overcharged, and a partial stagnation takes place, so that the economy of the whole system becomes obstructed, and cannot perform its several functions. The stomach cannot digest its contents; the lungs become oppressed, and have not the requisite freedom of expansion; consequently, if timely relief be not given, a catalogue of disorders must ensue, for nature always strives to unburthen herself in some way or other. When any symptom of approaching illness or disorder appears, which may discover itself in various ways, such as by the animal refusing his food, by the appearance of languor or dulness, heaviness of the eyes, heat in the mouth, swelling of the legs, itchings, breaking out in various parts, &c., it will then, in general, be proper to bleed, as a check, and also to allay the irritability of the system. In these cases, bleed according to size, constitution, and the nature of the forbidding symptoms of the attack. If a horse is very fat, the same quantity must not be taken from him that would be required were he in good working condition; for his fat, in the first place, debilitates him, and then taking blood in large quantities does this still further. We have known fat horses frequently fall, in consequence of five or six quarts of blood being taken from them at a time, from the erroneous idea that because they were fat, they could lose so much more blood. If, on showing any of the preceding named symptoms, and the horse happens to be overloaded with fat, great caution respecting bleeding should be shown, and not a too large quantity abstracted from him; but with horses in condition for work, five or six quarts may be taken without danger. In bleeding, sometimes, after pinning up the orifice, the horse shakes himself. If so, it may be taken as a sign that the object has been gained, and that the inflammatory action that was going on in the system, has been reduced.

If, however, symptoms and circumstances be compared together, to account, if possible, for
the cause of complaint; if the horse has been well kept, consequently full of flesh, and little or no work—for we do not call walking a horse about to stretch his limbs, sufficient to keep him in health—it may reasonably be concluded that the blood-vessels are prevented from performing their natural functions, and evacuations must relieve them. In this case, we prefer a course of alternatives to violent physicicking, as less dangerous.

It may so happen that a horse over-fed, and too little worked, may not discover any symptoms until after a day's riding, and work as some would call it, and from that circumstance it might not be attributed to the want of exercise; but here we deceive ourselves, for disease, or the seeds of disease, may have been lurking in the horse, and could not develop themselves until he was put to unusual exertion, which might necessarily cause the discovery sooner than it otherwise might take place.

If a horse has been in regular work or exercise, with a young and tender constitution, he will sicken at unusual exertion. This is termed, taking too much out of him; but, in such a case, the loss of a little blood, with two or three days' rest, will restore him. Sometimes, however, taking too much blood, and, at the same time, when the horse is very hot, suffering him to cool too fast, will, in all probability, instead of decreasing, increase any inflammatory disposition the system may be susceptible of; but if, at the first, we observe that he does not dung, or empty himself freely, as horses generally do when in health, this will draw attention to his state, and he must have speedy relief, to prevent disease coming on in a more dangerous form.

CONDITIONING THE HUNTER.

Every sportsman should know what are the best means to be adopted to get his hunters into condition, and the care and management necessary to their well-being during the season. Hunters are usually turned into good grass after the season is over, though a great deal has been said by some against such a practice. Still we have seen its good effects as often as stabling them; but one man may have convenience to stabl his hunters all the summer, and ten others may not have this; consequently, an additional expense would be incurred. But as that which we are about to write is for the use of hunting-men, we shall speak on general principles, which, from practice, we know to be correct.

Grass, it is well known, be it of ever so good a quality, is not a substantial food. It is cooling and opening; and though it makes a horse fleshy, nevertheless, it is not that description of flesh which a horse can work on. If we were to attempt to gallop him to the excess which frequently occurs in hunting, we should find him faint and weak, and the fat which has accumulated in the cellular membranous cavities, would be thrown off in the form of a white lathering sweat. This, if checked, might produce inflammation of the lungs, and the horse become a subject for the knackers. Therefore, the first thing to be done to alter this state of the system, in the best and most expeditious manner, is to bleed and physic, but with caution, always paying great attention to the constitution of the animal.

In the case of horses being taken up from grass, the warmth of the stable is very apt to incline them to itch, and to make them rub themselves a great deal. When they are so inclined, bleeding is highly necessary.

As horses usually have their shoes taken off when turned out to grass, the first thing to be done is to re-shoe him; then he should be bled according to his size; from two to four quarts of blood will be sufficient to take from him. After this let him stand quiet, with his head tied up to the rack, without food of any kind for three or four hours. While he is full of grass, he will not drink much water; but after living on dry food, he will drink plentifully if he is allowed. There is no necessity, however, for stinting him in water until he has taken his physic.

His coat will be exceedingly foul, and full of knots; therefore he will require some good dressings; and the opening of his coat, and the taking of the dirt out, will require him to be clothed. Accordingly, buckle a cloth on with a good broad roller, pretty tight, to assist in reducing the size of his belly. If he has been in the stable three or four days, and emptied the grass out of him, a dose of physic may first be given to him, preparatory to
which—the day on which he takes his medicine—he should be kept on cold bran mashes; then, at night, say an hour before the last visit to the stable, his medicine should be administered to him. The motive for giving the medicine at night, is because some horses having weakly constitutions, the medicine is apt to gripe them, which, on the following day, will be perceptible, and, with this advantage, it will occur in the day time, when every horse may have attention from any quarter it may be necessary to require it. Having done this, either tie him up close, or put on a muzzle, so that he may be kept without food all night. This, on giving him a little exercise in the morning, will occasion his medicine to operate much quicker than any other way. Immediately on returning to stable, give him a handful of the best hay—first having offered him some chilled water to drink—and a bran mash slightly warmed; for, from the sickness occasioned by the medicine, horses are, sometimes, with difficulty induced to eat anything warm during the operating of the physic; but in such cases, we have invariably horned down about two quarts of gruel at intervals, which, in a short time, has restored the tone of the stomach. This treatment, with good hay, is the only food necessary till his physic is set, as it is termed—that is, done working. Were more substantial food to be given, it might lessen the effect or operation of the physic, or be thrown out whole and undigested; consequently, it is best not to give any.

Here it is requisite to caution the gentleman or the groom, to be certain that the drugs, of which the medicine is composed, are genuine and good. There is no more serious evil than giving to a horse bad and cheap drugs; and we have experienced this evil to a very great extent, especially in the country. When we have sent a prescription to be made up, whether it has been from ignorance of the quality of the drugs, or whether from avarice, thinking a cheap or spurious article might do for a horse, we will not pretend to say; but physic, prepared with bad materials, not only deceives and disappoints its purchaser, but may do infinite mischief, even to the extent of causing the loss of a valuable horse. Therefore, we recommend physic to be bought of such vendors as are respectable, and who prepare it in large quantities. We recommend this, because such are not so likely to have stale drugs; and also are, from experience, likely to be good judges of their quality: whilst, giving a horse-prescription to an apothecary, or country druggist, he will probably prepare it with drugs that have been years in his shop, and perhaps, originally, not of the best quality.

Every groom should be expert at giving a ball. There is an art in doing this properly, which a looker-on cannot easily discover; and, as it is a material thing to give it well, we shall here point out such particulars as may assist the young practitioner.

In giving a ball, great celerity must be used; for if it is not done quickly, it becomes disagreeable to the horse, and difficult to the operator. A baling-iron is frequently used by those who are not expert at it, and it may be best for those who are not in the habit of giving balls; but those who are accustomed to give them, will do it as well, and sooner, without this instrument.

Before attempting to give the ball, you should be certain you are tall enough to reach, should the horse raise his head. Let the person who stands on the near side, and holds the mouth of the animal open, put the ball partly into your waistcoat pocket, so much remaining out, that you can easily take hold of it when you have drawn out the tongue of the horse. Stand before him, and take the farthest hold of the tongue with the left hand, drawing as much out of the mouth as it will admit, and in such a manner as will enable you to press it against his grinders, which will effectually prevent him from shutting his mouth. Having accomplished this, fold the right hand in as small a compass as possible, holding the ball at the extreme end with the three first fingers: then put it over the root of the tongue, thrusting it as far in as you can. This done, withdraw the hand, let go the tongue, and bridle the nose in a little, to prevent the horse from coughing it up. You must now wait patiently until you see it pass down, and be very attentive, for you cannot be too certain of having seen it swallowed. If he hesitates to let it pass down, elevate his head a little, and again bridle in the nose, and that will occasion him to swallow it. Some horses will, if you are
not mindful, hold the ball at the top of the throat, till you loosen the head, and then cough it up again; or suffer it to be lodged at the extremity of the grinders, when you will perceive them chewing it, and at last ejecting it from their mouths: if the whole of this operation be not done expertly, the horse will make the more resistance. We have seen awkward persons torment the horses, and spoil several balls, before they could get one fairly down.

As much water as he will drink may now be given. Warm water will occasion the physic to operate the sooner, if he will drink it; but, as before stated, offer gruel if he refuses the tepid water. After a few hours, give water that has been standing in the stable some hours; the raw chill will then be taken off, and will not hurt him. If the physic be prepared without colomel, or other mercurials, which is not proper medicine for conditioning horses, on such occasions cold water should never be administered. If all goes on well, and to your wish, you must not strip his cloth off, nor dress him till his physic has done working, which generally will be about the third day. While his physic is operating, he must not be taken out, though, if it can conveniently be done, he may be put in a loose box, which will afford him exercise quite sufficient until his physic is set. Great care should be exercised in keeping his hocks, legs, and thighs clean.

When the physic has so operated as to keep the body open for about twenty-four hours, giving him copious and loose stools, you may forbear using means of promoting further operation. Let him stand until his dung is set, and then give him his corn; strip and dress him well. The next day take him out, and give him gentle exercise.

About the sixth or seventh day from the time he took his first dose, the second may be administered, ordering the horse as directed before, and again letting the same time elapse between. The third dose may then be given; and this, in general, is sufficient to thoroughly cleanse him from that faint or foul condition which green food naturally occasions. Proper diet and exercise will then get him into wind and condition for hunting: but before we proceed with that part, we shall make some further remarks on physic.

We have noticed the manner of ordering a horse in physic, under the circumstances of the medicine properly operating and achieving its end satisfactorily; but, from various causes, it may so happen that physic does not take a proper course, or effect the expected object. If physic does not operate in the space of thirty-six hours, there must be some reason for it. It may proceed from its quality, or it may arise from the ball not being completely administered; for when a ball is not adeptly given, and the horse gets part of it in his teeth, he may only swallow a part, and the residue may be dropped in his litter, and never after be discovered. It may likewise proceed from the habit or constitution of the horse not being easily moved, so that he may require a stronger dose; and some animals will keep physic longer in them than others, before it operates.

Whatever the reason may be, we should not be in haste to administer another dose until we had used the ordinary expedients, and waited to observe the effects.

When physic does not operate in the space of thirty-six hours, keep the horse warm, for that will assist the operation, and administer about a quart of gruel, into which about a pint of cold ale may be put; warm and horn it down; then in a quarter of an hour afterwards, let him be moved about at a brisk walk, or gentle trot, but not sufficiently to heat him, or in anywise make him sweat. At night, give him a moderately warm mash, into which put about a handful of ground malt; and if it does not operate by the next morning, we should then be inclined to doubt whether he had really taken the physic, unless he has appeared sick, which will be known by his being heavy and dull, and refusing his hay. On the other hand, if he has only a soft evacuation, it may be in consequence of the warm gruel or mash which has been given him. But if he throws out a copious thin stool, having been sick with it, it may be concluded that he has had all his physic, or, at least, the greater part of it; yet, if his body is not kept open four-and-twenty hours, having several copious evacuations, we may consider his physic not to be sufficiently strong, and should increase the next dose accordingly; for, in general, the first dose of physic operates the most. We
therefore increase the second a little if we think it necessary, and particularly if we do not exactly know the constitution of the horse, it being safer to under-do than to over-do it: and by the second dose we can pretty well estimate what his constitution will bear, and, of course, proportion the dose accordingly.

On the other hand, it occasionally happens that physic operates too powerfully, owing to various causes, and sometimes to the constitution or habit of the horse's body. It may be that, at the time of administering physic, he is weaker than at other times; and sometimes it may be that the drugs are of a deleterious nature. In these cases, you will observe the horse only partially purge, accompanied by a kind of involuntary discharge, running down his hind quarters underneath, and all down his hocks and legs in a continuous wet and slimy kind of stream. On these occasions, the horse must be kept still, and great care taken that he does not take cold, whilst he should be wiped as dry and clean as possible. The evacuations being of a very sharp and acrimonious nature, if you find they do not abate in due course of time, proper remedies must be given, or the bowels may become so much irritated, that superpurgation may be the consequence. The best thing to give then is rice gruel, which is made in the following manner. Take a large teacup-full of rice, put it into a good-sized saucepan, and boil until the rice is perfectly soft, with two quarts of water. If the whole of the water is absorbed by the rice, put in two quarts more, and when this boils, take it off the fire, and strain it through a piece of tamis, squeezing the rice as much as you can. When this is done, break up the rice as fine as possible, and put it back into the gruel. When at a proper heat, give the horse about half, and, in about an hour, the remainder. Bran mashes must not now be given, but dry and strengthening food, if he will eat. If the first quantity of rice gruel does not have the desired effect, repeat it. This gruel may be improved by dissolving an ounce of gum-arabic to give with it, which will tend to remove the irritability, and, at the same time, strengthen the stomach, if impaired by the excessive operation of the purging medicine. When the purging has been thus excessive, we should let a clear week elapse from the time the dung was set, before we give another dose, to let the stomach and intestines recover their lost tone, occasionally administering the dissolved gum-arabic in his water, which will greatly assist that purpose. You must, consequently, be mindful that the next dose be less in quantity.

Horses having gone through their physic, you proceed, by proper exercise and diet, to get them into wind and condition for hunting. The physicking has taken between three and four weeks to get them cleansed from their soft foggy food, and now, about the same space of time is to be allowed to get the flesh firm, the coat clean, the limbs strengthened by exercise, and the wind improved by suitable management of diet. As so much pains has been taken to cleanse the body of soft and foggy food, we must now be careful that nothing but clean wholesome food should be given to the horse. For this purpose, a rack-rein and muzzle must be provided, and they must be alternately used. When the one is taken off, the other should be put on: for instance, put on the muzzle when it is expected that the horse will lie down at night. This is to prevent him from eating his litter, which some horses will do even when it is very foul. When fresh litter is given, many will prefer it to their hay: and although clean straw is not injurious to horses that are not required to gallop much, yet hunters and racers are not permitted to eat it, because it oppresses the wind. The rack-rein is an iron chain, fixed at the head of the stall, which passes through a ring sewed in front of the nose-band of the stall collar. It is fastened in the same manner as a dog's chain to the ring in the collar; and, when dressing the horse, it can, after passing it through the collar, be made to fasten him as short as may be thought proper; but, at other times, the chain must be long enough to permit the horse to feed out of his rack, or out of his manger, though not to let his head reach down to his litter.

The first thing to be done in the morning, on coming to stable, is to take off the muzzle and put on the rack-rein; then throw into the manger about a quart, or a little better, of oats, according to the constitution of the horse, for some are poor feeders, and must be treated in such manner as will best invite, or occasion
them to eat; while others, on the other hand, will eat all that is set before them, and must be stinted to a proper allowance. The oats, for these occasions, should be the best that can be procured—dry old oats, short and plump, clean from all kind of seeds, which are frequently to be found, particularly amongst foreign oats; perfectly sweet, free from dust, and white and clear. The oats should be well sifted, and the husks, chaff, or any light oats blown away, and the manger should be perfectly clean. When the horse has eaten his oats, clear his dung from behind him, but be careful not to disturb his wet litter, so as to occasion the vapour or stench to arise. You may strip off his cloths, rub the dung, if any, off his hind quarters, hocks, &c., and giving him a light brush over, put on his exercising cloth and saddle; then turn him round, brush his head and ears, put on his bridle, and take him out for exercise. The stripping and brushing are as refreshing to the horse as washing is to oneself after getting out of bed in the morning. While the horses are out at exercise, a person should be left at home to clear away all the wet dung, immediately setting doors and windows open, in order to have the stable sweet against their return, and all the stalls set fair, and the stable cleanly swept.

For exercise, choice should be made of the driest and most open piece of turf, sod, or heath that is in the neighbourhood, and, likewise where there is some gradual ascents, if of half a mile or a mile in length all the better, to give the horses some gentle breathings, in order to bring them into wind. They should be walked the first half hour, letting them empty themselves, yawn, stretch their necks, and enjoy the sweet refreshing morning air, which is invigorating, bracing, and strengthening both to man and beast. The walks should be so managed as to bring the horses about this time to a convenient place to give them a gentle gallop; beginning slow, and gradually increasing the pace till you finish at a half or three-quarters speed. The length of the gallop should be proportioned to the strength or condition of the horse. If he is faint, so as to sweat soon, stop in time, and walk him, that he may recover his breath, and cool himself. He must not be put into a thorough sweat, except on those days appointed for that purpose, which should be about twice a week till he commences hunting, and then he will not require any sweating in exercise. In this manner, alternately walk and gallop, so as not to sweat him till you find it time to return, which you should so manage as to keep him out about two hours. After the conclusion of the last gallop, the horse having recovered his breath, and cool, it should be contrived to have water at hand to let him drink, and then allow him an hour's walk home. If the water should chill him, and make his coat stare, a gentle gallop to warm him will be proper, but he must not be sweated.

Horses generally prefer to stable on litter, as they are not then splashed by it; and if the wet litter is spread in a convenient place, without the stable—some yards are thus purposely strewed—the horses, standing a minute or two before they are put in the stable, or during the time the groom dismounts, will stale, by which means the stable will be kept clean and healthy. When put into the stable, a bit of hay, well shaken from dust and seeds, should be given. The quality of hay for hunters should be the choicest that can be procured, grown on a rich meadow, and cut before it gets too ripe. Hay, when it stands too long before it is cut, may answer the farmer's purpose by seeding his ground, and wanting less making; but to be good for a horse, and especially a hunter, it should be cut when young, before it seeds, and with the sap in it. If it is then well made, and got in, in the dry, it will, fourteen months after, cut out as green as a leek, and the flowers will retain their beauty nearly as well as when growing. Hay will never be better than when twelve or fourteen months old; but such as we have described is not always to be procured; yet good meadow hay, that has not been heated too much in the stack, may be purchased very frequently. Indeed, we have heard some experienced followers of the chase say, that they preferred it a little brown; but, if it is twelve months old, having a fragrant sweet smell, it cannot be too green. New hay must not, on any account, be given. We give this caution because of the faintness which is in new hay, and which will be as detrimental as giving him grass; that is to say, if it is meant to preserve the horse in good hunting condition.

Having put the horse to the rack-rein with
IN THE PADDOCK.
a bit of hay before him, whisb his legs, for these ought always to be the first and last things attended to, and particularly after physic; then strip his clothing half off; that is, to about the middle of the back, and give the fore-quar-
ters a good thorough dressing. This being done, get dry clothing, and place on the parts cleaned, slip off the exercising cloths, and dress well his hind-quarters. This being done, re-
move the clothing from his fore-quarters, and brush him well over, agreeably to the manner we have before directed. After this, give his feed of oats, being double the quantity, or nearly so, to what was given before going out; then having whipped his legs as the last thing, shake up his litter, and set the stable fair; if he has cleaned the rack of the hay—for it is best to give but little at a time, that he may eat it with better appetite—you may give a bit more, if you think it necessary, but never give more than he will clear with a good appetite.

Having been up at the stable and out at exercise since five o'clock at this season of the year, it will now be high time to breakfast. Leave, therefore, the hunters on the rack-rein, while you are discussing your morning repast, and they will finish their hay.

On returning to the stable, observe that all have cleared their racks. If they have had sufficient time, and the racks not clear, take the hay away, loosen the rack-reins, put on the muzzles, and leave them for three hours quiet, that they may lie down if they are so disposed. It is a desirable thing for horses to rest their legs at all convenient opportunities.

This will bring you to what is termed middle day, or it may be one o'clock; for, as the days at this season are beginning to get shorter, you must be at the stable as punctual as the clock, so that you may contrive to be at home from exercise before dark. You should proceed now, in like manner, as in the morning, putting on the rack-rein, giving them a mouthful of hay, and a feed of oats in moderation; for they are not to be filled or incumbered with food, particularly hay, when they are going to be taken out. While the horses are feeding, clear the dung from behind them, as in the morning; then strip and brush them over previous to putting on their exercising cloths and saddles, and take them out, as in the morning. If you are situated in a country that affords a variety of suitable places for exercise, vary these as often as convenient. This will be the more agreeable to both horse and man. Keep off the gravel roads, choosing to go on the turf as much as possible. Having been out about two hours, in which time you have given the horses two gentle breathings, let them have water, and return.

The stable, as before, in your absence, should be cleared of all wet litter, and aired and re-
freshed against your return. After giving the horses the opportunity to stale, bring them into the stable, and repeat the rubbing of their legs, thoroughly dressing them, having, at the same time, given them a mouthful of hay to amuse them. After dressing, give them a feed of oats, and a bit more hay, if they have cleared the rack of what they had at coming in. This will bring you to about five o'clock in the afternoon, at which time you may leave them on the rack-rein to eat their hay; and between seven and eight return to finish up for the night. If a sufficiency was given them at leaving stable at five o'clock, they will need no more, the horses having had three hours to take their hay. If a horse is a slow feeder, he ought to have cleared his rack by this time; and such horses as have not done this, should have it taken from them; for the horse that is glutted with hay will not have any appetite for it; and as it is always standing by him, you should be mindful not to give too much, so as to occasion him to leave any. You have now to feed with oats for the last feed; see that all their cloths are put on right, not atwist, but smooth, and with-
out a wrinkle about them, and that every horse finishes his corn, not leaving any; then loosen the rack-rein, put on the muzzle, and make up a good bed. Having plenty of dry litter, and a large stall to lay his legs out at full length, leave him for the night.

This is the daily duty of the hunting stable, without any material difference, except on the days appropriated for sweating, which must be, at least, two in the week, till the hunting commences. When this takes place, and if the horse be hunted twice in the week, there will be no occasion for sweating exercise.

We would not recommend hunters to be kept over-warm with cloths. They are fre-
quently exposed to cold and wet; and the more tender they are kept, the more likely they are
to take cold; therefore, hoods and fillet-cloths may be dispensed with; but we think it highly necessary that each horse should have two cloths—one for exercise, which will occasionally be brought home wet and dirty; the other for putting on in the stable. The cloths should be occasionally scoured; and the exercising cloth, as often as it gets damp by rain, sweat, or dirt, carefully dried.

On the days for giving the horses sweating exercise, which may be on Tuesdays and Saturdays, or any other days equally distant, contrive that the sweats may be given as contiguous to home as possible, particularly if the air is thin and piercing. The object of this is to enable you to get home in good time for the purpose of scraping and rubbing them dry. When a horse is in a thorough sweat, and a chilling air penetrating under a wet cloth, he is almost sure to take cold, cough, &c.; therefore, the stable or rubbing-house should be conveniently at hand to prevent such a circumstance from occurring.

After having walked the animal for about an hour, bring him to the place where it is intended to gallop him, and begin very moderately, gradually increasing his speed till it attains to half or three-quarters, if he is hard to sweat. Continue him at that rate until he is in a proper perspiration, which will be sooner or later, according to his state. If he is fleshy and foggy, he will perspire soon, and his wind will be distressed. In this case, he must be galloped the slower, not to distress his wind, but to make him sweat, which will reduce his fat, and bring him into wind as that diminishes. If the horse is in good wind, and hard to sweat, his condition is improving, and stronger gallops may be given him without injury. The object and intention of these sweats are, to those that are in wind, to keep them so; and to those that are not in wind, by strong exercise, to get them into that desirable condition, by reducing all grossness arising from too much fat. The exercise, likewise, cleanses the coat, and makes it sleek and soft; for the imperceptible perspiration continually going on, adheres so closely to the roots of the hair or coat, that it is not easily got out; but these profuse sweatings bring it away, when, if the coat is well dressed after a good sweating, it becomes much finer.

The condition of the horse is to be discovered and judged of by his sweating. If he perspires soon, and puts on the appearance of soap lather, he is then what is called foggy, and must have strong exercise to carry it off. If he requires strong exercise to bring him to a sweat, and the sweat is clear like water, and dries soon, he is then in good condition, and fit for immediate work; but if he perspires profusely with little exertion, and it is thin, though like water, and he is a long time drying, it shows a weak, faint habit of body. Indeed, we may call it a bad constitution, that will not bear much work, especially as a hunter. Some horses sweat more profusely than others. This, however, is not always to be regarded as weakness, if it proceeds from strong exercise, and soon dries. Constitutions differ in horses as much as in men.

The horse having had his sweating gallop, should be brought into the stable, and well scraped and rubbed dry, with all possible dispatch. A clean dry cloth—not the one he has been sweated in—should be put upon him, and should be made clean against its being required again. If he had no water while out, give him some after he is perfectly cool and comfortable; and if the weather is cold, the chill should be taken off, but it need not be made warm. Water that has stood several hours in a warm stable, is sufficiently chilled, and may be given; or, after rubbing him, he may be walked about, and water given, and a gentle gallop taken, to warm him, but not to heat him. Then he should be brought home.

A horse treated in this manner will, in three or four weeks, after having been through his physie, be fit for hunting, if proper regard is paid to his feeding. His food should be of the best and cleanest quality, and the quantity should be regulated according to circumstances; such as size, constitution, &c., &c. Having arrived at this stage, the daily exercise of the horse will now be, on the average, not less than twenty miles a day. With this exercise, the quantity he eats will not hurt him, if he does not get too fat; for the hunter must have plenty of good feed, but must not be burdened with flesh. If he feeds heartily, he must have strong exercise to keep his flesh down. If inclined to run to belly and be fat, he must be stinted proportionably, or occa-
sionally given alterative medicine; but when
he comes to hunt three times a week, there will
be no necessity to stint him, and he will never
be burthened with flesh with such exercise.
The horse being got into condition, and the
hunting season commenced, the sweating pro-
ceases, and instead of giving exercise, to
keep his flesh down, and preserve his wind,
the exercise is now for the purpose of walking
off stiffness, occasioned by over-exertion;
bracing the system which may have been
relaxed by excessive work, and creating an
appetite. Hard running and long distances, con-
tinued for many hours, will affect a horse more
or less, particularly at the beginning of the
season; before he is accustomed to it, so that
his appetite will fail as well as his limbs become
stiff. Attention must, therefore, be turned
towards recovering him from that debility
which is caused by over-fatigue.
Young horses, and such as are not seasoned
for hunting, though in condition, are mostly
affected by severe days. These, therefore,
must not be expected to hunt more than one
day in the week; for it will take nearly the
rest of the week for them to recover from a
hard run, either with fox or stag. Seasoned
hunters, however, will stand their work twice,
and, in many cases, three times a week; though,
for a continuance, this is too much for any
horse, unless it is with barriers only, where
there is seldom much hard running.
To order the horses well when they hunt, feed
and dress them much after the same manner as
before directed; only, when going out in the
morning, rather shorten their allowance of hay
in the evening, and increase their corn, but do
not gorge them. They should always have a
good bed to invite them to lie down, and stretch
their legs; but the muzzles must be kept on;
for, though many do not constantly use these,
yet, if they be used at all, this is the most proper
time to do it. In the morning the horse should
be put on the rack-rein, but hay should not be
given him. This we would recommend for
constant practice; and if it is made a rule not
to give him hay until he comes home from
exercise, he will not pine, or look long for
it. If the distance is considerable where the
hounds are to meet, or if the covert be twelve
or more miles distance, the horse may have a
moderate feed of oats. Let him be thoroughly
cleaned, his legs well rubbed, and his saddle put
on, moderately girthed, at least an hour before
going out. This will cause him to empty him-
self; for most horses, when the saddle is put
on, relieve themselves by dunging if they can.
A quarter of an hour before wanted, put on
his bridile, and have him ready, buckling him
to the stall-reins. Let him stand till wanted,
with a cloth thrown over the saddle.
When a horse returns from hunting, it neces-
sarily follows that all expedition should be used
to get him clean, and made to feel comfortable.
If there has been very hard running, and he
comes home leg-wearied and tired, cleaning will
be more refreshing than feeding, and therefore
must be first attended to. He may have a sweet
bit of choice hay put into his rack to amuse
him, if he will eat while he is dressing; but
when it has been a long day, and hard riding,
many animals will be off their feed, particularly
young and unsasoned horses. This, as
a matter of course, is to be expected, though it
is most desired that they should feed, which is
a sign of a constitution for extraordinary
labour. On the hounds being drawn off, and the
day's hunt finished, the horse should be tho-
roughly cleaned. His head and ears should be
particularly well rubbed, and his body made
perfectly dry in every part. He should be
minutely examined to see that he has received
no injuries from stales, stumps, boughs, bram-
bles, thorns, rails, flints, &c.; likewise, that he
has not been galled with the saddle, girths, or
breast-plate, if he has worn one. When he
has been refreshed with a thorough good clean-
ing, he will be more inclined to feed than
before; but if he will not, his appetite will come
as his weariness wears off.
On returning home from hunting, it is usual
to let the horse drink—for he is sure to be
thirsty—at some convenient pond. But he
should not be suffered to drink too much at a
time. About ten go-downs will be sufficient,
till he is ridden to another convenient place,
where he may be allowed to have the like
quantity, and thus by degrees he will quench
his thirst before he gets home, which will be
better than letting him drink a vast quantity
of cold water at once. Should an opportunity
not have been had of giving him water on the
way home, he must, on his return, have it with
the chill off; and what is even better than this,
a bucket of chilled water, but not warm, into which a handful of oatmeal should be thrown. When his thirst has been partly quenched he will probably eat.

The legs, from excessive labour will, of course, be weary, and often inclined to heat and inflammation, particularly if the horse has been ridden among brambles, thorns, or furze. The greatest attention must, therefore, be paid to them. Hot water should always be ready against his being brought in from hunting, for the purpose of washing his legs; for nothing is more grateful and refreshing to these members, when they burn with heat and weariness, than soaking them well in hot water. It opens the pores of the skin, and draws out the heat. Let the water be hot, and bathe the legs well with it, having two pieces of woollen cloth, one to remain in the water, whilst the other is being used, so that by alternately changing them the leg will be kept constantly warm. Apply these well round the fetlock, joints, and pasterns. Do this for at least three-quarters of an hour; after which wipe them as dry as possible with a sponge; then carefully feel with your hands for any brambles or thorns that may be lodged in the skin; for the hand may now discover what the eye cannot perceive. Whatever may be found of this kind, must be picked out with care, so as not to enlarge the apertures they themselves have made, nor break or leave any part of them in. Much care, therefore, is necessary in extracting these foreign bodies; for they frequently produce a blemish, from the scab or scratch they occasion, by which the value of the horse is greatly deteriorated.

In some instances we have known thorns to penetrate so deep as to break within the skin; and, if such are not discovered, which it is sometimes difficult to do, an abscess will form. If this should be the case, immediately on discovering it, take linseed meal, four ounces, common turpentine, one ounce: mix well together with scalding water, and apply warm to the part affected, in the shape of poultice. This, in all probability, will draw out the offending particle; after which it must be dressed, as a common wound, with tincture of myrrh and aloes, three or four times a day.

A case of the above kind occurred with a valuable horse, when the village farrier was sent for. This professor opened the tumour on the top or upper part, the consequence of which was that there was little or no discharge. He then introduced a piece of tow saturated with butter of antimony; the consequence of which was a wound of an amazing extent. The veterinary surgeon was then sent for, when a few days' poulticing, accompanied with cooling medicine, produced a healing process; but the horse had always a blemish. Being a well-known good hunter, however, this did not take so much off his value as might have been expected.

Had the stupid fellow punctured below, instead of above the abscess, it would have relieved itself, and prevented the blemish, and, of course, the disagreeable eye-sore.

We mention this, in order to show the necessity of carefully examining for thorns. Should a similar circumstance happen, take a middling-sized abscess lancet, and open the abscess at the bottom. By this means the accumulated pus will discharge itself. Then treat as above. Apply a bandage round the part, which will keep the lips of the wound together, and accelerate the healing of it.

Having carefully searched, and extracted brambles or thorns, whip and wipe the legs perfectly dry. After this, and after the animal has had his water, if he will not feed, it is most likely for the best. Extraordinary exertion, perhaps, more than he has been seasoned to, may have caused an inward or sympathetic fever; and, until he has had rest, free circulation of air, and a little cooling medicine, the appetite will not return. In such a case give—Barbadoes aloes, one drachm; ginger, two drachms, formed into a ball, with half an ounce of common soap. Give this to the horse if his appetite has not returned by the morning after the chase. Some persons make themselves very uneasy on such occasions; and many are for giving a warm mash, which, of all things, the horse will not eat. Others are for giving a cordial ball, or something comfortable in the shape of a warm drink, all of which is of no use whatever. We recommend patience until the morrow; and if it should be deemed necessary, repeat the medicine. If nothing of a dangerous tendency exhibits itself, such as inflammation of the lungs, &c., make him up a good bed, and leave him to rest.

In the morning, the horse will, in all probability, feed a little; you must then proceed as
before directed, and take him out to exercise; after which, take linseed meal, two ounces, glauber salt, two ounces, warm water, three pints; give this drink the moment he comes in from exercise, and in the course of two days the horse will be fit for work again. Keep giving him sufficient exercise to take off that stiffness which naturally occurs from extraordinary exertion; and the fresh air will greatly contribute to recover his lost appetite.

Though we term this walking exercise, we do not mean that you are not to exceed a walk the whole time you are out. What we mean is to give the animal such exercise as will put the blood in free circulation without overheating it. A gentle gallop, therefore, may be given him for a short distance, but not such as will cause him to break out in a sweat, particularly after giving water: gallop by way of warming it. Choose the airiest place for exercise, such as open downs, or high and dry grounds; and when you return to stable, the horse, if he has not been very sick indeed, will have found his appetite.

Horses that become weary, and sicken at a day's hunt—which may be the case with even good animals, at the commencement of the season, or young horses, till they get properly seasoned to their work—will require some days to recover before they are fit to hunt again. A week's respite may be necessary with some; others will recover in half the time. The sooner the horse comes to his appetite, the sooner he will be fit for labour, provided he has not been nursed with warm mashes and comfortable drinks, as they are termed, which have a tendency to relax and open the body, and should only be given when he is in reality ill; but loss of appetite from over-fatigue only requires rest to be restored; therefore, avoid all the nostrums of the stable; which we are sorry, in too many instances, abound.

With regard to heat, or inflammation from the saddle or girths, washing the parts with goulard, is, perhaps, the best thing that can be done; and to the legs, if hot and swollen with fatigue, is the best repellant and cooler, and should be always kept ready at hand for such occasions. To prepare it, get a quart bottle, and take—extract of lead, 4 drachms; water sufficient to fill the bottle. The stable should never be without this lotion. It is cheap, efficacious, and ought always to be at hand. Washing the legs—which may have received scratches, &c., in hunting—with it, will heal them quicker than any other application.

The feet are likewise to be attended to at all times. On the horse's return home, all road-dirt, or gravel, should be carefully picked out; and particular care should be taken that no gravel is lodged under the shoe at the heels and quarters, as by such lodgment, corn may be produced, with all its natural consequences of tenderness and lameness. When the legs are washed with warm water to cool and refresh them, it will, at the same time, be well to relieve with it the feet, which must have undergone a considerable quantity of labour. Water is very beneficial to the feet, which are less injured by travelling on wet roads than on dry ones; and the hoof at grass, being continually wet with the dew and moist ground, is in a better state than when kept in the stable. The casual wet met with in exercise on the roads, or the moisture of the turf or grass, where exercise is given, will contribute to preserve the feet from the injury which continually standing in a hot and dry stable occasions. It is, perhaps, not too much to say, that one-half of the pleasure-horses kept in London, incur lameness, and are ruined by standing so much in the stable.

Training the hunter is a simple process, all that is required being to bring him into good wind, without, at the same time, reducing him too low in flesh, or injuring his sinews; since, on a long chase, more especially over a heavy country, a horse needs the aid of his full bodily strength, and of his unimpaired tendinous and muscular powers. It is extremely dangerous to ride over the country, a horse which is weak in his joints, or has the common hurt in his back sinews; but the danger is tenfold in taking a flying leap upon such an animal where the opposite descent is considerable, and the stress upon his lower limbs in his landing, with a heavy weight upon his back, must be excessive. Training must commence with two or three doses of physic should the horse be gross, and not have been previously trained. A young horse, in his first training, will require most work; but it is better rather to under-do than exceed in this, because if a horse come into the field rather
under-worked, being full of good meat and heart, the easy remedy is to favour and ride him carefully the first week or two; but should the training groom set you upon him harassed and weakened by too much exercise, he will get worse as the season advances, and, perhaps, be totally ruined by the end; exclusive of the risk of failing in a long and important day. Old hunters from spring grass, which they ever ought to enjoy, can scarcely be trained too lightly. The true test is, to see that their wind in its course is free and unembarrassed. To this point, however, their exercise must at any rate extend. The lighter the horse's clothing the better, in view of the heats and colds he must necessarily undergo in the chase. An early morning's gallop, at a good steady stride, but not speedy, of a mile or two, with a canter after water in the afternoon, is sufficient for the hunter, and two months ought to bring him into good condition. A young horse may have, once a week, a tolerably sharp rally for one or two miles, a method which should never be practised with a seasoned hunter; to which, indeed, walking exercise may be often substituted for the gallop.

Some think that even the simple process now described is not necessary, and that horses that are taken up and worked in the day, and with a feed or two of corn, and turned out at night, with an open stable or shed to run into if they please, are as active, healthy, and enduring, as those which are most carefully trained, and confined to the stable during the hunting season. Many a farmer has boasted that he could beat the most numerous and the best appointed field, and that his horse never wanted wind, and rarely tired.

It is true that the farmer may enjoy a good day's sport on the animal that carries him to market, or possibly, occasionally performs more menial drudgery; but the frothy lather with which such a horse is covered, in the early part of the day, unmistakably evinces his inferiority. There is, however, one point in which the untrained horse has the advantage. Accustomed to all weathers, he rarely suffers, when, after a sharp burst, there comes a sudden check, whilst the pampered and shivering stabled horse is exposed with him for a con-

considerable time to a piercing north-easter. The one cares nothing about it; the other may carry home the seeds of dangerous disease.

TRIMMING.

Many gentlemen attached to their horses, are sometimes fond of trimming them. This operation frequently fills up a leisure hour in the morning, and there is a self-gratification in being able to perform it without the assistance of any one. We have known some gentlemen so celebrated for squaring a horse's tail, that they have frequently been invited to perform that operation for many distant friends; consequently it will not be out of place to introduce the method of performing this operation in the most gentlemanly and skilful manner.

Trimming is one of the principal duties in the business of a groom, and every one who has the care of horses, should qualify himself to perform it, as it is allowed to set off an animal to much advantage. Many horses are exceedingly troublesome to trim, and, in order to accomplish it, require most extraordinary means to be adopted. We have known large sums of money given for trimming such troublesome horses. We are of opinion that the animals become so from the improper methods taken with them at first, by those who had not patience to coax, nor ability to accomplish by compulsion, and therefore employed such means as made the horse desolate, without being able to effect their purpose. Most horses have such a dislike to be trimmed, particularly about the head, that few stand without the twitch; and if they stand tolerably quiet with that, it is as much as can be expected; but if, with a little coaxing, it can be done without the twitch, it will be the better. There is great care, skill, and judgment required in trimming; care, that you do no injury, by the unsteadiness of the horse, with your scissors; skill, that you may not disfigure him by scoring, notching, and the like; and judgment to trim him in such a style as will be most proper and advantageous to his appearance.

Begin at the head—first, with the foretop, and clip close and smooth only that part on the forehead which is in the way of the front of the bridal and stall-collar. Next clip away that
part on the poll, where the head-stall of the bridle, or stall-collars come, taking care to remove as little towards the neck as possible; or, if the animal is clipped beyond where the head-stall of the bridle comes, it will disfigure the neck. The next point is to trim out the ear, which will be found a little difficult to do; and few horses will stand quiet to have it done without being pinched with the twitch.

The scissors most handy for trimming ears, are such as are narrow in the blades, the points not too sharp, but well cut. Begin with clipping the inner part of the ear, going not too near the edges, till the long hair on the inside is cleared out; then gradually approach the edges, drawing the outside skin of the ear-back, so as not to clip so close as to leave the edge of the ear bare, and thereby disfigure it. The outside skin of this organ is very loose; and as it is held with the left hand, while being clipped with the right, it is apt to be drawn so far forward as to deceive the operator, by making him clip too near the edge. Care must therefore be taken that no notches or scallops appear on this part. Having clipped to the edges, and no farther, the outside hair will stand projecting beyond these, quite even and regular if the operation has been properly done.

At the bar and root of the ear, a quantity of long flossy hair grows, which must be partly clipped away, and that on the inside must not be left in scores and notches. You finish with the scissors, by clipping the hair that projects round the edge of the ear, cutting it all round, so as to preserve the exact beauty and shape of the organ, leaving, to be singed at the root, a quantity of hair which the scissors would only score.

All superfluous hair about the face and beard, under the eyes, and about the nose and lips, should be clipped as closely as possible. Rough horses, lately come from grass, and coarse-bred ones, have a quantity of unnecessary hair growing very thick under the throat, and about the throat. This must be removed.

The fore-legs are the next parts to be handled, and great pains should be taken with them. Thorough-bred animals, kept in the stable, and properly groomed, seldom require trimming about these members, as all superfluous hair rubs off with their dressings. When lately taken in from grass, however, a little long hair will appear on the back sinews, and on the fetlock-joints, which may be taken off, by using a small quantity of powdered resin, say as much as may be taken up between the finger and thumb; and this will remove it with as much ease to the horse, as facility to the person trimming. Let the compressed hairs be cut to any length, provided no ridges will be seen; and if properly done, it will scarcely be perceived that it has been touched. The coarser the breed of the animal, the more useless hair will be found on the legs, and within the pastern. Where it is abundant, it must be removed with the scissors, beginning next to the heel. Clip it clean out within the pastern, and under the fetlock-joint. The adjoining part will then be able to be so nicely tapered, that the sudden break from short to long will not appear, which otherwise would be the case. The soft spongy piece of flesh at the back extremity of the pastern-joints, can be pared down, if necessary, with a sharp knife, and the portions above left in such a manner as to resemble the legs of a thorough-bred horse. The hair, up the back sinews, must be raised with the comb, and cut in equal lengths, tapering it towards the sinew, in such a way as to prevent the appearance of all scores or ridges, allowing that portion next to the back sinews to be the shortest.

As there are some horses a little bent at the knee, the hair, within that joint, should not be clipped too close, as it will make that defect appear more conspicuous, and defeat the object of trimming, which is to make the animal appear to more advantage than belonged to it before the operation was put in practice. Care must, therefore, be taken to conceal as many of the defects as exist. Where the legs are straight, however, all the flossy hair within that joint may be removed. Round the coronet of the hoofs the hair should be clipped regular and even. The four legs being thus trimmed, there only remains the tail for the further operation of the scissors; for the mane, unless it is what is called hagged, must not be touched with that instrument.

As fashion and fancy are ever wavering, the tail and ears have always been subject to such changes as are agreeable to the taste of the
times. At one period, a switch tail; at another; a full bushy tail; then a blood tail; then another; and then again a short switch tail, about a foot and a-half long. This being the case, it may here be as well to make a few remarks upon them separately and individually.

The switch tail requires no cutting; the long hair being left on it after the end of the dock is broken off, is pulled underneath, and at the sides, with an iron instrument, made for the purpose—but now seldom to be seen, except in the carter's stables—till it is tapered to a point, leaving only about eight inches below the dock.

There is much reason in this sort of tail, seeing that nature designed this appendage to strike the flies from the bodies of such animals as are possessed of one. Man, however, to accommodate himself, denudes the brute of its natural property, simply because the tail annoys him when it is switched about in hot or dirty weather, thus depriving the animal of that which was intended for its own especial comfort.

The bushy tail is permitted, to preserve all the hair that grows upon it. Holding the tail to that elevation in which the animal usually carries it, the scissors are employed to cut in a perpendicular direction, within about half an inch of the end of the dock. There is much art and ingenuity in cutting tails of this kind perfectly square, leaving both sides of equal length, and permitting no projections or hollows at the end.

The brush-tail was formerly deemed suitable to such horses as were well nicked, and carried it high, and bent upwards. A tail of this kind was rounded in such a manner, that, when it was up, it resembled the hair of a brush. Much ingenuity is required to cut it true and even.

The blood tail has been in vogue for many years, and is perhaps the most becoming of any. It requires the least art or ingenuity in cutting. The hair has only to be combed out and held together with the left hand, when the ends are cut off square, at a proper length, generally about three inches below the end of the dock. After this it is combed out, and any irregularities that may appear are taken away. The hair of the blood horse's tail is generally thin, and of an easy flowing nature; and having always a becoming appearance, is, as we have said, greatly in fashion.

The thin tail is a mean representation of the blood tail; and tails of half or inferior bred horses, are fuller and more bushy than those of blood animals. Hence, to bring these to some resemblance of the blood tail, the under hair is plucked to thin it, and by such means they are made to appear like a thin ragged tail. The ends are squared in the same manner as blood tails are done.

Thin-tailed horses have, in general, been remarked to be good ones. But the difference between them and blood animals is easily discovered; and for this reason should, perhaps, be more properly denominated ragged-tailed.

After all these operations, which we have so minutely described, there only remains for the mane to be pulled and singed. To do this, first, comb it thoroughly, laying it very smooth and even. Then begin at the top, and taking hold of a few of the longest hairs at the points with the right hand, separate them from the other hair, by moving the comb in an upward direction. If you have hold of no more than would be about the thickness of a straw, twist the hair round the back of the comb, and pluck it out. Continue to act in like manner till that part is reduced to the thinness and length desired. Proceed in the same way down the mane, making all alike, and repeatedly combing it out. Hairs left longer than the rest must be plucked, not cut. The fore-top is a great ornament, and should be left long, so that it will tuck under the bridle, and reach three or four inches below. The extreme ragged points may be taken off with the scissors, so that the mane may be left thin at the points. It is not to be squared, however, so as to look thick and bushy. Singeing now finishes the operation of trimming. Rough horses, newly taken from grass, usually require a good deal of singeing all over, they having long downy hair projecting beyond the rest of their coats.

For the purpose of singeing, a candle with a large wick is required, and the head is the first part to commence with. The long downy hair which projects beyond the rest, may be singed to a level with the coat. The outside of the ears will have some; and there will be much at the bur of these. The candle must not be kept long in one place, or it may burn the animal; therefore, where there is much singeing required, it is better to rub the singed part, to
let it cool, and apply the candle again. Take
care, however, not to continue this so long as
to blister the skin. The places which want the
most singeing, are at the root of the ears, the
throat, about the throat, and the adjoining
part of the neck. Put the hand now over the
eyes, and singe all the light straggling hairs
perceived about them and the brows, forehead,
cheeks, beard, and the like. The throat and
throat require many repetitions, the hair being
so abundant and thick, that it is extremely
necessary that frequent wipings be resorted to,
to see that the singeing has not been performed
irregularly.

The head and throat being operated upon,
and finished, with a candle, the remaining parts
of the body are to be singed with straw. For
this purpose, take as much long clean straw at
a time as has about the thickness of three
fingers, and lighting one end, begin at the neck,
and pass the flame from one part to another.
Great care must be taken not to singe the
mane; proceeding thereon to the chest, should-
ers, breast, and every part where long and
downy hair is perceived projecting beyond
the general coat, being cautious not to make
the blaze too large, or continue it too long in
one place, particularly where there is but little
hair, as under the flank, and within the thighs,
&c. Then giving the horse a good wiping,
and brushing over completely, the trimming is
finished.

We may observe, that horses which have
been kept for a time in the stable, and pro-
cerely groomed, have not those long downy
coats, and consequently do not require singe-
ing all over the body. The beard, the ears,
mane, and the tail, are generally all that a
blood animal requires to be trimmed when he
is kept in the stable. Coarser animals, how-
ever, require the heels and other parts to be
trimmed, though the coat may be kept in
such a state as not to stand in need of it.
We have observed that some horses are trouble-
some to trim. The means usually adopted, in
addition to the twitch on the nose, or some-
times on the ear, are those of the gag with
the halter, put through the mouth, and over
the ear: the more that horses struggle with
these appliances, the more they gag and pinch
themselves.

To keep the legs still, while trimming, a
person should be employed to hold up one
while the other is undergoing the operation.
If a hind leg, a side-line may be put on to
draw up the other, which is not being trimmed.
These are the usual expedients, but they
ought only to be in practice when the horse
cannot be coaxed to stand without them.

An abundance of litter in the stall is ad-
visable, as it may prevent accidents in the
event of the horse struggling hard whilst
undergoing the operation.

FOOD.

In regulating the food of a horse, the first
points to be attended to are quality and quan-
tity, which ought to be proportioned to his
habit of body or constitution, and the nature
of his work. If the quality is bad, it will make
him foul, and will not afford the same degree
of nutriment that clean wholesome food will
yield: if he is fed too plentifully for the work
or exercise he has, it will make him too fleshy
and gross, and probably do him material injury.
Again, if a disproportionate quantity of hay is
given, it will cause him to drink too freely;
blowing him out with a description of food
which affords the least nutriment. A horse
thus fed cannot endure much labour, and his
wind becomes distressed.

Hay, however, is the natural food for horses,
but is not sufficiently strengthening for
them to work upon now-a-days; therefore, to
be kept in condition, they must be fed
sparingly with it, although it be of the very best
quality. The quantity necessary for a horse
depends much on his size, constitution, and
the nature of the work he has to perform.
Hence, if he is put to fast work, his food
should be of that quality that affords the most
nutriment, that lies in the smallest compass,
and requires the least water to digest it.
When these are attended to, his wind will be
the least distressed. If his work is hard, that
is, continued for several hours, but not at any
extraordinary speed, he may have a greater
quantity of hay, and even of beans with his
oats. Chaff, if sweet and good, is proper for
some animals that have thin light carcasses, and
not worked hard. Such as eat their corn greedily
without masticating it, and settle it among
their litter, should have a handful or two of
good sweet clover chaff, which will be infinitely
serviceable, as it will oblige them to chew or masticate their oats with the chaff before they can swallow it. But though chaff is filling, it must be sparingly given, as it fills them up, and inclines them to drink much, when they will appear plump and fair, but not in condition for work. It is most proper for slow draught horses.

The quantity of hay necessary for a saddle-horse, is from eight to sixteen pounds per day, according to size, constitution, and his work. About twelve pounds will be found generally sufficient; but large carriage horses require from sixteen to twenty pounds. If horses get lank and hollow in the flank and quarters, their allowance should be increased; but, on the contrary, and for the sake of having them fat and plump, they must not be supplied with too much hay and water. An animal when fat, is less fit for work than when lean, provided his leanness is not occasioned by starvation, for he may be rendered poor by his work exceeding his keep. If a horse is stinted to an allowance that keeps him in tolerable condition with only a little walking exercise, and then put to work without an increase of food, he will, of course, become thin; but if not given so much work as to exhaust his strength, as well as his flesh, he will be nothing the worse for it. Increase his food, and he will be better for work than before.

Oats of quality are the most nutritious food for saddle-horses, when given in proper quantities; say three-quarters per day, provided his work is no more than exercise; but if the horse is kept to constant hard work, he is in no danger of being over-fed if he has as much as he can eat. The qualities of oats will be discussed further on.

Beans are excellent and stimulating for hard-worked animals; but of their properties we shall speak under their own specific headings. Here, however, we may observe that the small and plump bean is usually the best, by all means, for such horses as are either lightly worked or required to go at speed, as they need more water to digest them, and swell in the stomach. They may, however, be allowed to animals that travel at a moderate rate, or such as are employed in draught work. They are also good for coach or omnibus horses if given in small quantities.

Water is usually given twice a day; some, however, give it three times; but this plan of watering does not do so well for travelling as for draught horses. Soft water is esteemed preferable to hard spring water; hence rivers and running streams, or such springs as supply ponds, where the water gets impregnated and softened by a loamy or chalky soil, is better than hard spring pump water. The quantity in this, as in food, must also be regulated by circumstances, size of horse, constitution, &c. Some animals will not drink immoderately, and may safely be left to their discretion; while others, if permitted, will swill, and render themselves incapable of work, by causing immoderate perspiration and distress of wind. When the work is done for the day, a reasonable quantity may be allowed. Half a stable-pailful of water is generally sufficient for the morning.

**MANGER-FEEDING.**

The system of manger-feeding which has now, for some years, been adopted on the road, arose no doubt from a desire in the proprietors of horses to fill the stomachs of their animals in the shortest possible space of time, in order that they might get more rest on the road; and among farmers it is becoming more general. It is certainly well adapted for horses not over-worked through speed; whilst it is an economical way of feeding, as by mixing a portion of chaff with the corn and beans, the animal is compelled to chew his food. He cannot bolt the straw or hay; and while forced to grind the chaff, he also grinds the oats and beans. By the adoption of this plan more nourishment is yielded, and the stomach is more slowly filled. Independently of this, the increased quantity of saliva thrown out in the lengthened grinding operation softens the food, and renders it better fitted for digestion.

Chaff may be composed of equal quantities of clover or meadow hay, and wheaten, oaten, or barley straw, cut into pieces of a quarter or half an inch in length, and mixed well together; the quantity of oats or beans is afterwards added, and mixed with it. The beans and oats should be bruised, because the whole oat is apt to slip out of the chaff and be lost; but when it is bruised, and especially if the chaff is a little wetted, this will be less likely

130
MANGER-FEEDING. [MANGER-FEEDING

Horses take great delight in this provender; but damaged straw should not be used for making chaff, as the corn it contains may tempt a horse to eat, even if it be not good. More injury is done by eating damaged hay or musty oats, than is generally imagined. Therefore the advantage of this system of manger-feeding, will, as a matter of course, be entirely counteracted, if it be made the vehicle for the consumption of unwholesome materials. One of the most important advantages to be derived from manger-feeding is, that the animal, by the union of eating nutritious matter with the more bulky kind (hay-chaff), his stomach is filled the sooner, and has, consequently, more time for rest—a very considerable consequence to a horse on the road.

Where the manger system of feeding is not adopted, or where the hay is still given at night, and chaff and corn in the day, there is no error into which the farmer is so apt to fall as that of giving an undue quantity of hay, and that generally of the worst kind. If the manger system is good, there can be no necessity for hay; or if there is, only for a small quantity of it; but if the rack is overloaded, the greedy horse will be eating all night, instead of taking his rest; and when the time for the morning feed arrives, his stomach will already be filled. He will then, from the want of sleep, be less capable of work, and from the long-continued distention of the stomach rendering it impossible for his food to have been properly digested.

It is a good practice to sprinkle the hay with water in which salt has been dissolved, as it is more palatable to the animal. Indeed, the horse will leave the best unsalted hay for that of an inferior quality which has been moistened with brine; and there can be no doubt that the salt very materially assists the process of digestion. The preferable way to use the salt is to sprinkle it over the different layers as the rack is formed. From its attraction for water, it would combine with that excess of moisture, which, in wet seasons, is the cause of too rapid and violent fermentation, and of the hay becoming mouldy, or the rack sometimes catching fire, and it would become more incorporated with the hay. The only objection to its being thus used is, that the colour of the hay is not so bright; but
this would be of little consequence for home consumption.

The comparative advantages of chaff and rack-feeding, are thus given by Professor Stewart:

"Where the stablemen are careful, waste of fodder is diminished, but not prevented, by feeding from the manger.

"Where the racks are good, careful stablemen may prevent nearly all waste of fodder, without cutting it.

"An accurate distribution of fodder is not a very important object.

"No horse seems to like his corn the better for being mingled with chaff.

"Among half-starved horses, chaff-cutting promotes the consumption of damaged fodder.

"Full-fed horses, rather than eat the mixture of sound with unsound, will reject the whole, or eat less than their work demands.

"Chaff is more easily eaten than hay. This is an advantage to old horses and others working all day—a disadvantage when the horses stand long in the stable.

"Chaff ensures complete mastication and deliberate digestion of the corn. It is of considerable, and of most importance in this respect. All the fodder need not to be mingled with the corn; one pound of chaff being sufficient to secure the mastication and slow ingestion of four pounds of corn.

"The cost of cutting all the fodder, especially for heavy horses, is repaid only when hay is dear, and wasted in large quantities.

"Among hard-working horses, bad food should never be cut."

We will now briefly enumerate the principal vegetables which enter into the food of the horse.

OATS.

In almost every part of Great Britain, oats have been selected as that portion of the food which is to afford the principal nourishment. They contain seven hundred and forty-three parts out of a thousand, of nutritive matter, and should be old, heavy, dry, and sweet. New oats will weigh ten or fifteen per cent. more than old; but the difference consists principally in watery matter, which is gradually evaporated. New oats are not so easily ground down by the teeth as old ones, and form a more glutinous mass, difficult to digest. Therefore, when eaten in considerable quantities, they are apt to become so unwholesome as to occasion colic, and even staggers. Oats should be plump, bright in colour, and free from unpleasant taste or smell. The musty smell of wetted or damaged corn, is caused by a fungus which grows upon the seed, and which has an injurious effect on the urinary organs, and often on the intestines, producing profuse staling, inflammation of the kidney or colic, and also of the bowels. This musty smell may be removed by kiln-drying the oats, but care should be taken that too great a degree of heat is not employed. This, however, should be sufficient to destroy the fungus, without injuring the vitality of the seed. Kiln-burnt oats are not so grateful to the animal, as they acquire a heating quality, which not un frequently produces inflammation of the eyes, and many affections of the skin. All the expense of threshing the unthreshed oat-straw would be saved if cut for chaff. It is better than barley straw, but does not contain so much nourishment as that of wheat. When the horse is fed on hay and oats, the quantity of the latter must vary with his size and the work to be performed. Nine or ten pounds a day will be a fair allowance for one of fifteen hands one or two inches high, in moderate work, with a proportionate quantity of hay. In summer, when green food is given daily, reduce the quantity one-half. Such animals as work on the farm, have from ten to fourteen pounds, and the hunter from twelve to sixteen. There is no kind of food that can be safely substituted for good oats; as they have an inherent strengthening property which is not possessed by other kinds of food.

For the weary and tired horse, a pint of oatmeal thrown into a pail of water, is an admirable drink. It forms, also, an excellent gruel for the sick horse, leaving it to be drunk of his own accord when slung in his box, and water is denied him. As a poultice it is also excellent, having more stimulating properties than linseed meal when used alone.

BARLEY.

Barley is a common food of the horse on various parts of the continent, and, before the introduction of oats, seems to have constituted
almost his only food. It is more nutritious than oats, containing nine hundred and twenty parts of nutritive matter in every thousand. There seems, however, to be something necessary besides a great proportion of nutritive matter, in order to render any substance wholesome, strengthening, or fattening. Where horses are very hardly worked, barley does not seem to agree with them so well as oats. They are more subject to inflammatory complaints, and particularly to surfeit and mange. When barley is given, the quantity should not exceed a peck daily. It should be always bruised, and the chaff should consist of equal proportions of hay and barley-straw, and not be cut too short. If the farmer has a quantity of spotted or unsalable barley which he wishes thus to get rid of, he must very gradually accustom his horses to it, or he will probably produce serious illness among them. For animals that are recovering from illness, barley, in the form of malt, is often serviceable, as tempting their appetite and restoring their strength. It is best given in mashes—water, considerably below the boiling heat, being poured upon it, and the vessel or pail kept covered for half an hour.

GRAINS.

Grains fresh from the mash-tub, either alone or mixed with oats or chaff, or both, may be occasionally given to draught horses; they would, however, afford very insufficient nourishment for such as are employed in quicker or harder work.

WHEAT.

Wheat is, in Great Britain, more rarely given than barley. It contains nine hundred and fifty-five parts of nutritive matter. When farmers have a damaged or unmarketable sample, they sometimes give it to their horses, and, being at first used in small quantities, they become accustomed to it, and thrive and work well. It must, however, always be bruised and given in chaff. Wheat contains a greater proportion of gluten or sticky adhesive matter than any other kind of grain. It is difficult of digestion, and apt to cake and form obstructions in the bowels. This will oftener be the case if the horse is suffered to drink much water soon after feeding upon it. This circumstance arises from the water passing rapidly through the stomach and small intestines, in its way to the cæcum, carrying off with it all the starch, which is the most nourishing property of wheat, and leaving the sticky mass behind to accumulate and harden, and obstruct the intestines, and frequently to destroy the animal. A horse that is fed on wheat should have very little hay. The proportion should not be more than one truss of hay to two of straw.

Wheaten flour, boiled in water to the thickness of starch, is given with good effect in over-purging, and this especially if combined with chalk and opium.

BEANS.

Beans contain only five hundred and seventy parts of nutritive matter, yet they add considerably to the strength of the horse. This fact forms a striking illustration of the principle, that the nourishing or strengthening effects of the different articles of food, depend more upon some peculiar property which they have, or some combination which they form, than on their actual quantity of nutritive matter. There are many horses that will not stand hard work without beans being mingled with their food. Those that have a tendency to purge, it may be necessary to restrain by the astringency of the bean. There is no traveller who is not aware of the difference in the spirit and endurance of his horse, whether he allows or denies him beans on his journey. They afford not merely a temporary stimulus, but they may be daily used without losing their power, or producing exhaustion. Two pounds of beans may, with advantage, be mixed with the chaff of the agricultural horse, during the winter. In summer, the quantity should be lessened, or they should be altogether discontinued. They are generally given whole, which is very absurd; for the young horse, the teeth of which are strong, seldom requires them; while the old horse, to which they are in a manner necessary, is scarcely able to masticate them. He, from being unable to break them, swallows many whole, and drops much corn from his mouth, in the ineffectual attempt to crush them. Beans should not be merely split, but bruised. They will even then give sufficient employment to
the grinders of the animal. Some postmasters use chaff with beans instead of oats. With hardly-worked horses they may possibly be allowed; but in general cases, beans, without oats, would be too binding and stimulating, and would produce costiveness, and probably megrims or staggers. Neither the hard-worked coach-horse, nor the washly one, nor the old one, could perform their tasks without them. To turf horses they are sometimes given as a stimulant. The straw of the bean is highly nutritive, and is usually given to horses.

PEAS.

Peas are occasionally given, and appear to be, in a slight degree, more nourishing than beans, and not so heating. They contain five hundred and seventy-four parts of nutritive matter. For horses of slow work they may be used; but the quantity of chaff should be increased, and a few oats added. They have not been found to answer with animals of quick draught. It is essential that they should be crushed; otherwise, on account of their globular form, they are apt to escape from the teeth, and many are swallowed whole. Exposed to warmth and moisture in the stomach, they swell very much, and may painfully and injuriously distend it. Many horses have died from gorging themselves with peas; and, on opening them, their stomachs have been found to have burst by the swelling of the vegetable. In proof of the swelling property of them, let a small phial be filled with them, tightly corked, and warm water poured upon it; the peas will burst it in a few hours.

In some northern countries, the meal of the pen is not only given as food to the horses, but, in cases of diabetes, is used as a remedy.

TARES.

Of the value of tares, as forming a portion of the late spring and summer food of the stabled and agricultural horse, there can be no doubt. They are very nutritive, and act as a gentle opening medicine. When surfeit-lumps appear on the skin, the horse begins to rub himself against the divisions of the stall, and the legs swell, and the heels threaten to crack: a few tares cut up with the chaff, or given instead of a portion of the hay, will often afford, sometimes immediate, and generally rapid relief. Ten or twelve pounds may be supplied daily, and half of that weight of hay subtracted. It is an erroneous notion, that, given in moderate quantities, they either roughen the coat or lessen the capability for hard work. Tares furnish a greater proportion of food for a limited time than almost any other kind of forage crop.

RYE GRASS.

Rye grass supplies a valuable article of food, but is inferior to the tare. It is not so nutritive; is apt to scour; and occasionally, late in the spring, it has appeared to become injurios to the horse.

CLOVER.

Clover, for soiling the horse, is inferior to the tare and the rye grass, but nevertheless is useful when these cannot be obtained. Clover hay is, perhaps, preferable to meadow hay for chaff. It will sometimes tempt the sick animal, and may be given with advantage to horses of slow and heavy draught; but custom seems properly to have forbidden it to the hunter and the hackney.

LUCERN.

Lucern, where it can be obtained, is to be preferred even to tares, and sainfoin is superior to lucern. Although they contain but a small quantity of nutritive matter, it is easily digested, and perfectly assimilated. They speedily put both muscle and fat on the horse that is worn down by labour, and they are almost a specific for hide-bound. Some farmers have thought so highly of lucern as to substitute it for oats. This may do for the agricultural horse of slow and not heavy work; but the animal from which speedier action is sometimes required, as well as the one of all work, must have a proportion of hard meat within him.

THE SWEDISH TURNIP.

This root is an article of food the value of which has not been sufficiently appreciated, and particularly for agricultural horses. It does not contain much nutrition, but is easy of digestion, quickly fattens the animal, and produces a glossy skin. It may be given once a day—at night after the work is done, when it will be extremely grateful.
CARROTS.

The virtues of this root are not sufficiently esteemed, adding to the strength and stamina of the horse in health or in sickness. Some farmers allow a bushel of sliced carrots a-day, with chaff, without any oats; and the horses are said to be equal to all slow or agricultural work. Stewart, in his Stable Economy, remarks, that "this root is held in much esteem. There is none better, nor, perhaps, so good. When first given, it is slightly diuretic and laxative; but, as the horse becomes accustomed to it, these effects cease to be produced. They also improve the state of the skin. They form a good substitute for grass, and an excellent alternative for horses out of condition. To sick and idle horses they render corn unnecessary. They are beneficial in all chronic diseases connected with breathing, and have a marked influence upon chronic cough and broken wind. They are serviceable in diseases of the skin, and, in combination with oats, they restore a worn horse much sooner than oats alone."

POTATOES.

Potatoes have been sliced and given with advantage in their raw state, mixed with the chaff; but, where there has been convenience to boil or steam them, the benefit has been much greater. Some have given boiled potatoes alone; and horses, instead of turning from them, have come to prefer them even to the oat; but it is better to mix them with the manger feed, in the proportion of one pound of potatoes to two-and-a-half of the other ingredients. Professor Low says, that fifteen pounds of potatoes yield as much nourishment as four-and-a-half of oats. Von Thayer says, that three bushels are equal to one hundred and twelve pounds of hay; and Curwen says, that an acre of potatoes, in the feeding of horses, goes as far as four acres of hay. In feeding a horse on this root his water must be much curtailed.

BREAD FOR CATTLE AND HORSES.

The French frequently feed their horses on bread; and various other attempts at economy are practised out of the common management of feeding them with raw corn, which, no doubt, may be beneficial. We have heard of a team of horses, at Liverpool, to which boiled corn was always given, and the water boiled afterwards to drink. This was said to nourish them at much less expense than the common method of feeding adopted.

It is equally necessary to seek for economical food for cattle as for man. To lessen the consumption of food in rearing, preserving, and maintaining the health and strength of cattle, is to save so much for the benefit of mankind. Many neglected plants, growing in marshy ground, the tender leaves of different trees deprived of their resin by infusion, chopped straw, &c., are substances and resources which may be, and are in many instances, usefully employed.

In Sweden, oat bread is used for horses, and is found much cheaper and more salutary than the simple grain. It may be remarked that horses always pass some parts of the oats they have eaten, whole; their stomachs labour much to digest food, some part of which is entirely lost, and is even dangerous to them. Oats ground and baked would not occasion these inconveniences.

Experience has shown, that in Sweden, one ton of oats makes four hundred and eighty loaves, on which a horse may be better kept—at the rate of two loaves a day—for two hundred and forty days, than if he had had six tons or even more of raw oats. The husk of the oats remains mixed with the flour; and the weight of the water, a large quantity of which is necessarily employed in making the dough, is gained. It has also been calculated in Sweden, that after all expenses have been taken into consideration, a great saving is effected by feeding horses on bread made of oats and rye. There hay is never given without mixing it with two-thirds of chopped straw, and adding to it bread broken up. The better to preserve this bread, it should be made in the shape of cakes; and if it be prepared like biscuit, it will keep for a lengthened period of time, without losing its nutritive qualities.

Good bread for cattle may be made from the farinaceous parts of the horse-chestnut, acorns, mandragora, dog's-grass, &c. These substances may be used in the composition of bread for cattle, together with potatoes reduced to powder.

In all agricultural experiments, we must
ever allow ourselves to be discouraged: creatures accustomed to a particular diet, will sometimes refuse a superior one for that to which they are habituated. It should be frequently presented to them, and before long they will relish it. Why should not leaves, chaff, straw, heath, fern, &c., reduced to powder, be mixed with this bread? Beetroot, or potatoes and flour, will serve as a vehicle for all these substances; whilst experience soon proves the quantities for producing the necessary proportions to form the required material of a substantial consistence.

In closing this portion of our work, it may be desirable to many to be made acquainted with the nourishing properties known, by chemical analysis, to exist in several of the most necessary vegetables.

1,000 parts of wheat contain 955 parts of putritive matter; barley, 920; oats, 743; peas, 574; beans, 570; potatoes, 230; red beet, 148; parsnips, 99; carrots, 98.

Of the grasses, 1,000 parts of the meadow cat's-tail, contain at the time of seeding, 98 parts of nutritive matter; narrow-leaved meadow grass in seed, and sweet-scented soft grass in flower, 95; narrow-leaved and flat-stalked meadow grass in flower, fertile meadow grass in seed, and tall fescue, in flower, 93; sweet-scented soft grass, in flower, and the aftermath, 77; flaxen cutin, 76; tall fescue, in the aftermath, and meadow soft grass, in flower, 74; cabbage, 73; crested dog's-tail, and bronse, when flowering, 71; yellow oat, in flower, 66; Swedish turnips, 64; common turnips, 42; sainfoin, and broad-leaved and long-rooted clover, 39; white clover, 32; and lucern, 23.

TURNING OUT TO GRASS, OR THE STRAW-YARD.

When horses have been hard worked, turning out becomes a natural consequence, to refresh their limbs: they are occasionally turned out when not wanted for present use. The hunter, when the season is over, is turned into good grass, which cools the system, and prevents too great an incumbrance on the master's pocket. It also refreshes his limbs, which, if he has been regularly hunted throughout the season, stand in need of it. If, however, he has only occasionally been so, and is now wanted for the road, there is no necessity for turning him out. We have heard of horses having been kept in a stable twelve years without eating any green food, yet have continued in health and condition; while there are some constitutions that will not look well in the stable for almost any continuance of time, but soon suffer from indigestion, and hide-bound, when their coats assume a chill and russet hue. Grass, however, is by no means improper for horses. On the contrary, it is good, and such as are kept for pleasure, and only moderately used, may be put to grass, and yet, with a little corn, worked occasionally all the summer.

Turning-out in winter to a straw-yard, is a practice with those who maintain a horse for pleasure in summer, and have no occasion for him in winter. Those who cannot afford the expense of keeping a horse in the stable in winter, endeavour to persuade themselves that it is beneficial to the animal to be put into the straw-yard, and famished with cold and hunger for five or six months. Consequently, this practice is not to be recommended. Far better to sell the animal if the expense of stabling him cannot be afforded.

When gentlemen have convenience of their own to turn horses out in winter, there is no doubt of their being taken care of. In open weather there is good pasturage; and in hard weather, an out-house or stable to lie in, with plenty of hay. But as we are here speaking of straw-yards, where all that come are taken in, the practice of sending them to such repositories is a dangerous, if not a bad one. Not but that some animals may seem well enough when they are deeply bedded with clean and wholesome straw, of which they can pull the ears to fill themselves; but where they are taken in for pay, some men scarcely ever think their yards are overstocked, and provender, which is scarcely fit for the horses to lie upon, becomes their food.

Giving green food in the stable is called soiling. It is not often convenient for those who keep no more horses than they have use for, to turn them out to grass, more particularly in a season when people take pleasure on horseback, or travel on business. The work of animals of this description is hardly to be called exercise; which frequently consists of an
average, of not more than ten miles a day, and at a pace seldom exceeding more than six or eight miles an hour. Under such circumstances, green food in the stable has a cooling influence, and acts as an alternative, and therefore should be given. Indeed, there are some constitutions that do not thrive without it, dry food for a long continuance of time not agreeing with them, but making them lank and thin. Such descriptions of horses are hardly worth keeping, except for light work, as their paces and action may be very pleasing.

Green food being a kind of natural physic, cooling, and operating as a gentle laxative, many deny the necessity of any other kind of medicine. In its operative principle, more especially if the animal works on it, his litter will be very soft, if he does not quite scour. This is a great benefit to the horse, by clearing out the alimentary canal, and producing that healthy secretion of functions nature is so desirous of. After a time, however, the purgative principle passes off, and he voids his dung in rather a soft state than otherwise. An animal kept on green food should not be put to immoderate work, as it may produce inflammation of the intestines, and its frequent consequence—death.

To those who have not given this part of our subject the consideration it merits, it may be as well to observe, that green food, when cut, soon spoils. Therefore, those who buy the bundles of vetches or tares which are brought into market, must be careful to see that they are fresh and cool. Such vegetables being frequently cut the day before, and tied up in bundle, are full of moisture, and become heated, and soon begin to rot. They should, therefore, be fresh every day, and no more taken in than can be consumed, as they soon spoil if they happen to be pretty moist. If, therefore, there is no certainty of a regular supply, a good plan is to untie the bundles, and spread them on the spare room of the floor of the hay-loft. This will preserve them fresh for two or three days. Should the animals be in the habit of feeding on chaff, it is good policy to have a layer of vetches cut up with it. This will be found cooling and refreshing, especially if the weather is warm, and the horses in full work.

**Physicking.**

In the course of this work we shall have occasion to make reference to cathartic and other balls. Those which, from experience, have been found the most beneficial, we have arranged in the subjoined form, and distinguished them by numbers, so that an easy reference, at all times, may be made to the different ingredients of which they are composed.

**No. 1.***

Barbadoes Aloe . . . . 1 oz.
Ginger (powdered fine) . . . . 2 drachms.

If for immediate use, form into a ball, with treacle; but if not, with soft soap. When the horse is properly prepared with bran muffes, as directed in our preceding pages—"On the Management of Hunters"—this ball will be found sufficiently strong for any animal.

**No. 2.***

Barbadoes Aloe . . . . 6 drachms.
Ginger . . . . . . 1 "

Form into a ball, as prescribed for No. 1. This ball is generally found strong enough for saddle-horses of all descriptions.

**No. 3.***

Barbadoes Aloe . . . . 4 drachms.
Ginger . . . . . . 1 "

Though this quantity of aloe will act as a drastic purge on some constitutions, it will scarcely move others. In the above formulae of purgative medicines, you have simply those that actually stimulate the intestines to get rid of their contents.

**No. 4.***

Barbadoes Aloe . . . . 5 drachms.
Cape Aloe . . . . . . 5 "
Ginger . . . . . . 2 "

Mix, and form into a ball, with soft soap, for large carriage or cart horses; then treat as above. This will be found to prove pretty effective.
CHAPTER VI.

BREEDING; BREAKING-IN; CASTRATION.

BREEDING.

Having already touched upon this important subject, we shall here more particularly enter into it; for it is unquestionable, that within the last thirty years our horses have undergone a considerable change. The opinion, among those who may be supposed to be the best capable of forming a correct judgment, is, that there are fewer good hacks and hunters than there were formerly; and, if such be the case, it must necessarily form one of the first considerations of breeders to endeavour to discover the causes of this deterioration, and to adopt such means as may be the most likely to restore the breed, as well as to improve the character of our horses. Whether considered socially or nationally, this is an object of too much importance to be neglected.

Our observations will here be of a general nature, and will be very simple. The first axiom we would lay down is, that "like produces like;" that the progeny will inherit the qualities of its parents. Referring to the subject of diseases, we must again state our conviction, that there is scarcely one affliction by which either of the parents is affected, that the foal will not inherit, or, at least, exhibit a predisposition to. So certain is this the case, that it may safely be affirmed that even ill usage or hard work, where either has been so excessive as to lay the seeds of disease in the parents, such disease will indubitably be found to descend to their progeny. Undeniable evidence, repeated again and again, has decided the fact, that blindness, roaring, thick wind, broken wind, spavins, curbs, ring-bones, and founder, have been bequeathed, both by the sire and the dam, to the offspring. It should likewise be recollected, that although these blemishes may not appear in the immediate progeny, they frequently will in the next generation. Hence the necessity of some knowledge of the parentage both of sire and dam. Mr. Baker, of Reigate, speaking of his own experience in this matter, says—"A foal had apparently clear and good eyes; but the first day had not passed before it was evident that it was totally blind. It had Gutta Serena.

"Inquiry was then made about the sire, for the mare had good eyes. His were, on the slightest inspection, evidently bad; and not one of his colts had escaped the direful effects of his imperfect vision.

"A mare had been the subject of farceal enlargement; and not being capable of performing much work, a foal was procured from her. She survived; but the foal, soon after birth, evinced symptoms of farcey, and died.

"A mare was lame from navicular disease. A foal was bred from her, that, at five years, could scarcely go across the country, and was sold for a few pounds. The mare was a rank jib in single harness; the foal was as bad."

Peculiarity of form and constitution are also inherited. This is a most important, but neglected consideration; for however desirable or even perfect may have been the conformation of the sire, every good point may be neutralised by the defective form, or want of blood, in the mare. There are niceties here, of which some breeders were wont to be aware, and they employed their knowledge to prevent it to great advantage. When they were careful that the essential points were good in both parents, and that some minor defect in either should be met, and got rid of, by excellence in that particular point in the other, the result was creditable to their judgment, and highly profitable. Other breeders, less skilful, often so badly paired the animals, that the good points of each were, in a manner, lost. The defects of both were increased, and the produce far inferior to both sire and dam.

Of late years, these principles have been much lost sight of in the breeding of horses for general use; and the following is the explanation of it. There are nearly as good stallions as there used to be. Few horses but such as are well-formed and valuable, will be selected and
retained as stallions. They are always the very prime of the breed; but the mares are not what they used to be. Poverty has induced many of the breeders to part with those from which they used to raise their stock, and which were worth their weight in gold; and the jade on which the farmer now rides to market, or which he employs on his farm, costs him but little money, and is only kept because he cannot get much money for her. It has, likewise, become the fashion for gentlemen to ride mares, almost as frequently as geldings; and thus the better kind are taken from the breeding service, until old age or injury renders them worth little for that purpose.

In the third volume of The Veterinarian, this will be found strikingly pointed out by Mr. Castley, an intelligent veterinary surgeon. It ought to be as deeply impressed as possible on the minds of breeders, that peculiarity of form and constitution are inherited from both parents; that the excellence of the mare is a point of quite as much importance as that of the horse; and that out of a sorry mare, let the horse be as perfect as he may, a good foal will rarely be produced. All this is recognised upon the turf, although poverty or carelessness has made the general breeder neglect or forget it.

In the midland counties it is recognised in matching the breed of cart-horses; and the strict attention which has been paid to it, has brought our heavy draught animals to almost the same perfection, in their way, as it has brought our blood horses. It is an unaccountable fact, however, that in our saddle-horses, our hunters, and, to a great extent, our carriage-horses, this should be left to chance.

That the constitution and endurance of the horse are inherited, no sporting man ever doubted. The qualities of the sire or the dam descend from generation to generation, and the excellencies or defects of certain animals, are traced, and justly so, to some peculiarity in a far-distant ancestor.

It may, perhaps, be affirmed with justice, that there is more difficulty in selecting a good mare to breed from, than a good horse, because she should possess qualities somewhat opposite. That sufficient room may be given for the growth of the foetus, her carcase should be long, and yet with this there should be compactness of form and shortness of leg. What can be expected from the practice of those who purchase worn-out, spavin'd, soundered mares, about which they fancy there have been some good points, and send them far into the country to breed from; and, with all their variety of shape, to be covered by the same horse? In a lottery like this, there may be, now and then, a prize, but there must be many blanks. If horse-breeders, possessed of good judgment, would pay the same attention to breed and shape as Mr. Bakewell did in sheep, they would probably attain their wishes in an equal degree, and greatly to their advantage, whether for the collar or the road, for racing or for hunting.

As to the shape of the stallion, little satisfactory can be said. It must depend on that of the mare, and the kind of horse wished to be bred; but if there is one point which we should say is absolutely essential, it is this, "compactness"—as much goodness and strength as possible, condensed into a little space.

Next to compactness, the inclination of the shoulder will be regarded. A huge stallion, with upright shoulders, never got a capital hunter or hackney. From him the breeder can obtain nothing but a cart or dray-horse, and that, perhaps, spoiled by the opposite form of the mare. On the other hand, an upright shoulder is desirable, if not absolutely necessary, when a mere slow draught animal is required.

It is of no little importance, that the parents should be in full possession of their natural strength and powers. It is a common error to suppose that because a mare has once been good, she may profitably be used to breed from when she is no longer capable of ordinary work. Her blood and perfect frame may ensure a foal of some value, but he will inherit a portion of the worn-out constitution of her from whom he sprung.

On the subject of breeding in and in—that is, persevering in the same breed, and selecting the best on either side—much has been said. The system of crossing requires larger experience and judgment, perhaps much larger than breeders usually possess. The bad qualities of the cross are too soon engraven on the original stock; and once engraven there,
are not, for many generations, eradicated. The good qualities of both are occasionally neutralised to a most mortifying degree. On the other hand, it is the fact, however some may deny it, that strict confinement to one breed, no matter how valuable or perfect, produces gradual deterioration. The truth here, as in many other cases, lies in pursuing the middle course. Crossing should be attempted with great caution, and the most valuable points of the same breed should be preserved, but varied, by being frequently taken from different stocks, with reference to either one or more excellences which these may have been discovered to possess. This is the secret of the turf. The pure south-eastern blood is never left, but the stock is often changed with manifest advantage.

A mare is capable of breeding at three or four years old. Some have injudiciously commenced to breed at two years old, before the form or strength of the mare is sufficiently developed, and with the development of which this early breeding will materially interfere. If she does little more than farm work, she may continue to be bred from, until she is nearly twenty; but if she has been severely worked, and bears the marks of it, let her have been what she might in her youth, she will deceive the expectations of the breeder in her old age.

The mare comes into "season" about February, and continues "horsing," at intervals, until the end of June or middle of July. Her term of gestation is from eleven to twelve months; but some have been six weeks beyond the eleven months. We may take, however, eleven months as the average. In running horses that are brought so early to the starting-post, and whether they are foaled early in January or late in April, rank as of the same age, it is of importance that the mare should go to cover as early as possible. For other breeds, the beginning of May is the most convenient period. The mare would then foal in the early part of the following April, when there would begin to be sufficient food for her and her colt, without confining them much to the stable.

From the time of covering to a few days before the expectation of foaling, the draught mare may be kept at moderate work, not only without injury, but with decided advantage. Her labour may be continued up to the very time when she is expected to foal—of which she will give at least a day's notice, by the adhesive matter that will appear about her teats. When this is observed, it will be prudent to release her from work, and keep her near home, and under the frequent inspection of some careful person.

When nearly half the time of pregnancy has elapsed, the mare should have a little better food. She should be allowed one or two feeds of corn in the day. This is about the period when mares are accustomed to sink or abort their foals, or when abortion occurs. At this time, therefore, the eye of the owner should be frequently upon them. Good feeding and moderate exercise will be the best preventives against any mishap that may be likely to occur. The mare that has once slunk her foal is ever liable to a similar accident again, and therefore should never be suffered to be with other mares about the time that this usually occurs, which is between the fourth and fifth months; for such is the power of imagination or of sympathy in the mare, that if one suffers abortion, several others in the same pasture will be certain also to prove abortive and share the same fate. Farmers wash, paint, and tar their stables to prevent some supposed infection. The infection lies in the imagination.

If a mare has been regularly exercised, and apparently in health while she was in foal, little danger will attend the act of parturition. If otherwise, and any signs of danger, it will be better to have recourse to a well-informed practitioner, rather than run the risk of injuring the mother by the violent, and frequently injudicious attempts which are often made to relieve the animal.

So soon as parturition has taken place, the mare should be turned into some well-sheltered pasture, with a hovel or shed to run into when she pleases; and as, supposing she has foaled in April, the grass is scanty, she should have a couple of feeds of corn daily. The breeder may depend upon it, that nothing is gained by starving the mother and stinting the foal at this time. It is the most important crisis in the life of the horse; and if, from false economy, his growth is arrested, his puny form and want of endurance will ever afterwards testify to the error that has been committed. The corn should be given in a trough
on the ground, that the foal may partake of it with the mother. When the new grass is abundant, the quantity of corn may be gradually lessened.

After foaling, the mare may be made to perform a moderate amount of labour in about a month. The foal is at first shut in the stable during the hours of work; but as soon as it acquires sufficient strength to toddle after the mare, and especially when she is at slow work, it will be better for the foal and the dam that they should be together. The work will contribute to the health of the mother; the foal will more frequently draw the milk, and thrive better, and will be hardy and tractable, and gradually familiarised with the objects among which it is afterwards to live. While the mother, however, is thus worked, she and the foal should be well fed; and two feeds of corn, at least, should be added to the green food which is supplied to them when turned out after their work, and at night. The mare will usually be found again in "season," at or before the expiration of a month from the time of foaling, when, if she be kept principally for breeding purposes, she may be put again to the horse.

To return, however, to the foal. It is not generally known that the refusing to suck, which is the cause of the death of many foals, as well as the scouring, which about the third day kills many more, are both produced by irritation, and consequent inflammation of the bowels, from the retention of a few small hard faces in the rectum. These are generally more in quantity in proportion as the keep of the mare has been high.

The cure is simple— a few hours after the foal has been dropped, a tallow candle should invariably be passed into the rectum; and when the passage has been sufficiently softened, the faces can easily be extracted by the finger.

In cases where scouring kills foals at a subsequent period, it is generally to be attributed to the foal heating itself by violent exercise. Consequently the mare, for the first day or two that she is let out— supposing her to be housed— ought only to be walked about with a halter, and the same practice pursued at the time of her first "horsing."

Some mares will not allow their foals to suck. This arises from the tenderness of their teats.

In such cases they should have their heads tied up, and, if necessary, be otherwise prevented from kicking while they are milked by hand. The milk should be rubbed over the teats for a short time, after which they will allow the foal to suck.

Should the mare's milk be obstructed and fail, either from her having taken cold or other cause, if out, she should immediately be taken up to the house, and enticed to lie down upon a large and deep-littered bed of fresh straw, in a loose box, and every method adopted to comfort her, and to encourage the secretion of milk.

To promote this end, as much warm mild ale should be allowed as she will drink. Should she refuse this she may be drenched with a couple of quarts, to be repeated as frequently as may appear necessary— her food being the finest and most fragrant hay, sweet grains, with mashers of corn and pollard. In cases of chill, and great weakness, the old well-known article, cordial ball, may be given in warm ale.

Should, however, the case be inflammatory, from previous high condition and fulness of blood, CORDIAL BALL AND ALL STIMULANTS SHOULD BE STRICTLY AVOIDED, and the regimen confined to warm water and gruel, in as copious quantities as can be administered. Should further measures of similar tendency be indicated, a mild solution of Epsom salts— ten or twelve ounces in a pail of warm water— may be given, which she may be induced to drink by means of being kept short of water. Should the symptoms demand it, a moderate quantity of blood may be drawn, but not otherwise. Daily walking exercise abroad, the mare being clothed, if necessary, should follow this treatment, until she is sufficiently recovered to be returned to her pasture.

During her inability to give suck, the foal must be sustained on cow's milk. This alien milk will generally disorder and grip the foal, for which the best remedy is two or three spoonfuls of rhubarb in powder, with an equal quantity of magnesia, in warm gruel. This medicine should be given to the foals of working mares, which are often gripped by sucking pent milk. The disorder arising from wet and cold, a table spoonful each, of the best brandy and syrup of white poppies, may be given several times.

Mares that give birth early, and in bad weather,
should invariably be brought to the house to foal.

Mares travelling with young foals ought not to go above fifteen miles a day, and their pace should be entirely regulated by the natural pace of the foals, which must never be hurried so that they be left behind. Every mile or two the mares should be allowed to stop a little, and the foal be permitted to suck and rest itself. Thus the journey ought to occupy the whole of the day.

Mares having dead foals, ought to lose a little blood, be fed moderately on cooling mashed with a little nitre, and on no account be allowed corn. Moderate walking exercise is very desirable for mares before foaling; and alternate mashes of plain and of scalded bran are much to be recommended.

It should be observed that geldings must not be admitted among the brood mares, as by leaping them, or harassing them about, abortion may be occasioned.

In five or six months, according to the growth of the foal, it may be weaned. It should then be housed for three weeks or a month. There can be no better place for this than the rick-yard, as affording both food and shelter. The mother should then be put to harder work, and have drier meat. One or two wine balls, or a physic ball, will be useful if the milk should be troublesome, or she should pine after her foal.

There is no principle of greater importance than the liberal feeding of the foal during the whole of his growth, and at this time in particular. Bruised oats and bran should form a considerable part of his daily provender. Should a dairy be upon the ground, a plentiful supply of new milk will, in a wonderful degree, hasten his development. The farmer may be assured that money is well laid out which is expended on the liberal nourishment of the growing colt; yet, while he is well fed, he should not be rendered delicate by excess of care. A racing colt is often stabled; but one that is destined to be a hunter, a hackney, or an agricultural horse, should merely have a square rick, under the leeward side of which he may shelter himself; or a hovel, into which he may go at night, or at any time run out of the rain.—By attending to these observations, their good effects will soon make themselves apparent.

The process of breaking-in should commence from the very period of weaning. The foal should be daily handled, partially dressed, accustomed to the halter, led about, and even tied up. The tractability, and good temper, and value of the horse, depend a great deal more upon this than breeders are aware. Everything should be done as much as possible by the man by whom the colts are fed, and whose management of them should be always kind and gentle. There is no fault for which a breeder should more emphatically correct his servant than for harshness towards the rising stock; for the principle on which their after usefulness is founded, is early attachment to, and confidence in man; and obedience, implicit obedience, resulting principally from his attentions.

There is nothing of greater importance to the owner of the horse than his being well broken. To insure this, great care should be taken to put the animal under the care of a man well qualified for his duties; for nothing is easier than to spoil the mouth of a horse, if left to the management of an injudicious person. It has been observed that more horses have been spoiled in the breaking than can ever be recovered afterwards, even if mounted by the most skilful riders.

After the second winter, the work of breaking-in the cart colt may commence in good earnest. The animal may first be bitted, with such an instrument as will not hurt his mouth, and much smaller than such bits as are in common use. With this he may be suffered to amuse himself, and to play, and to champ for an hour, on a few successive days.

Having become a little tractable, portions of the harness may be put upon him, and, last of all, the blind winkers. In a few days afterwards he may go into the team. It would add to his confidence and feeling of security if another horse could be put before and another behind him, besides the shaft horse. Let there be first only the empty waggon, and let nothing be done to him, except that he may have an occasional pat or kind word. His companion horses will keep him moving, and in his place. In some instances not much time passes, not even the first day, before he
The agricultural horse is wanted to ride as well as to draw. His first lesson should, therefore, be given when he is in the team. Let his feeder, if possible, be first put upon him: he will be too much hampered by his harness, and by the other horses, to make much resistance; and, in the majority of cases, will quietly and at once submit. In riding, no whip or spur should be used in giving the animal his first lessons.

When he begins to understand his business, backing, the most difficult part of his work, may be taught him. To accomplish this he must first be made to back well without anything behind him, then with a light cart, and afterwards with some heavier load, taking the greatest care not seriously to hurt the mouth. If the first lesson causes soreness or inflammation of the gums, the colt will not readily submit to a second. If he has been rendered tractable before, by kind usage, time and patience will do all that can be wished here. Some carters are in the habit of blinding the colt when teaching him to back. This may be necessary with the restive and obstinate one, but it should be resorted to only when all other attempts to back him have failed. It is an admirable plan to teach a horse to back without blinkers, for many accidents have occurred from horses having had their bridles slipped off, and through not being accustomed to see the vehicle behind them, have become terrified, and set off at full speed, to the destruction often of themselves and of whatever object with which they may come in contact.

The colt having been thus partially broken-in, the necessity of implicit obedience may be taught him. This is not to be done by severity, but by firmness and steadiness. The voice will go a great way, but whip or spur is sometimes indispensable. The application of either of these instruments, however, is not to be of such a severe kind as to excite the animal to resistance, but to convince him that his driver or master has the power to enforce submission. Few horses are naturally of a vicious disposition. It is generally bad usage which has first provoked resistance, which has brought upon them severer chastisement, and which, as a matter of course, the fear or the stubbornness of the quadruped has still further increased. Open warfare then ensues; dislike takes place on both sides; the man hates the horse, and the horse hates the man; when both are rendered unfit to perform their duties properly together. Correction may, or must be used, to enforce implicit obedience after the education has proceeded to a certain extent, but the early lessons should be incubated with kindness alone. Young colts are sometimes very perverse; many days will occasionally pass before they will permit the bridle to be put on, or the saddle to be worn; but one act of harshness will often double or treble this time. Patience and kindness will, after a while, prevail. This, succeeded by additional kindness and soothing on the part of the breaker, and no inconvenience or pain being suffered by the animal, all resistance becomes at an end.

The same principles will apply to the breaking-in of the horse for the road or the chase. The handling, and some portion of instruction, should, as we have said, commence from the time of weaning. The future tractability of the animal depends much on this. At two years and a-half, or three years, the regular process of breaking-in should come on. If it be delayed until the horse is four years old, his strength and obstinacy will be more difficult to overcome. A headstall is put on the colt, and a cavesson, or apparatus to confine and pinch the nose, affixed to it, with long reins. He is first accustomed to rein, then led round a ring on soft ground, and at length mounted and taught his paces. Next to preserving his temper and docility, there is nothing of so much importance as to teach him every pace, and every part of his duty, distinctly and thoroughly. Each must constitute a separate and sometimes long-continued lesson, taught by a man who will never suffer his own temper to overcome his discretion.

After the cavesson has been attached to the headstall, and the long rein put on, the first lesson is, to have him led quietly about by the breaker. A steady boy should follow behind, and occasionally threaten with the whip, but never give an actual blow, his only duty being to keep the colt up. When the animal follows readily and quietly, he may be taken to the ring, and walked round, right and left, in a very
small circle. Care should be taken to teach him this pace thoroughly, never suffering him to break into a trot. The boy with his whip may here again be necessary, but not a single blow should ever be administered.

Becoming tolerably perfect in the walk, he should be quickened to a trot, and kept steadily at it; the whip of the boy, if needful, urging him on, and the cavesson restraining him. These lessons should be short. The pace should be kept perfect and distinct in each, and docility and improvement rewarded with frequent caresses and handfuls of corn. The length of the rein may now be gradually increased, the pace quickened, and the time extended, until the animal becomes tractable in these his first lessons; towards the conclusion of which, crupper-straps, or something similar, may be attached to the clothing. These, playing about the sides and flanks, accustom him to the flapping of the coat of the rider. Any annoyance which they may at first occasion will pass over in a day or two, when the animal finds that no harm to him arises from them.

Next comes the bitting. The bit should be large and smooth, and the reins should be buckled to a ring on either side of the pad. The reins should at first be slack, and very gradually tightened. The object of this is to prepare the animal for the more perfect manner in which the head will be afterwards got into its proper position, when he is accustomed to the saddle. Occasionally the breaker should stand in front of the colt, and take hold of each side-rein near to the mouth, and press upon it, which is a mode of beginning to teach him to stop and to back at the pressure of the rein. Every act of this sort should be rewarded by some soft or gentle endearments, and no eagerness or desire to punish any occasional carelessness or waywardness which the yet unbroken animal may be inclined to display.

The colt may now be taken into the road or street to be gradually accustomed to the objects among which his services will be required. Here, from fear or playfulness, a considerable degree of starting and shying may be exhibited. As little notice as possible should be taken of these symptoms of timidity or wildness. The same or a similar object should be soon passed again, but at a greater distance. If the colt still shies, let the distance be farther increased, until he takes no notice of the object; then he may be gradually brought nearer to it, usually without the slightest difficulty. If, however, there is an attempt made to force him close to it in the first instance, the remembrance of the contest, which such an act generally causes, will be associated with the object, and the habit of shying will be established.

Hitherto, with a cool and patient breaker, the whip may have been shown, but will scarcely have been used. The colt must now, however, be accustomed to this instrument of authority. Let the breaker walk by the side of the animal, and throw his right arm over his back, holding the reins in his left, and occasionally quickening his pace, let the horse be touched with the whip very gently. It is astonishing how soon the association of the touch of the whip and the quickening of the pace become fixed in the mind of the animal. If necessary, the touches may gradually fall a little heavier, and the feeling of pain be the monitor of the necessity of increased exertion. The lessons of reining in, stopping, and backing on the pressure of the bit, may continue to be practised at the same time.

He may now be taught to bear the saddle. Some little caution will be necessary in putting it on at the first. The breaker should stand at the head of the colt, pat him, and engage his attention, while one assistant, on the off-side, gently places it on the back. Another, on the near side, will then slowly tighten the girths. If the animal submits quietly to this, as he generally will, when the previous process of breaking-in has been properly conducted, the ceremony of mounting may be attempted on the following or on the third day. The breaker will need two assistants to accomplish this operation. He will remain at the head of the colt, patting and making much of him. The rider will then put his foot into the stirrup, and bear a little weight upon it, while the man on the off-side presses equally on the other stirrup-leather; and, according to the docility of the animal, he will gradually increase the weight, until he balances himself on the stirrup. If the colt is uneasy or fearful, he should be spoken kindly to and patted, or a mouthful of corn given to him: but if he offers serious resistance, the lessons must terminate for that
day; he may probably be in better humour on
the next.

When the rider has balanced himself for a
minute or two, he may gently throw his leg
over, and quietly seat himself. The breaker
will then lead the animal round the ring,
the rider sitting perfectly still. After a few
minutes he will take the reins, and handle
them as gently as possible, guiding the horse by
the pressure of them; patting him frequently,
and especially when he thinks of dismounting;
and, after having dismounted, offering him a
little corn or green meat. The use of the rein
in checking him, and of the pressure of the leg
and the touch of the heel in quickening his
pace, will soon be taught him; when the educa-
tion will be nearly completed.

The horse having thus far submitted himself
to the breaker, these pattings and rewards
must be gradually diminished; and implicit
obedience mildly but firmly enforced. Severity
will not often be necessary. In the great
majority of cases it will be altogether uncalled
for: but should the animal, in a moment of
waywardness, dispute the command of the
breaker, he must, at once, be taught that he is
the slave of man, who has the power, by other
means than those of kindness, to bend him to
his will. The plan of the education of the
horse is similar to that which experience and
wisdom have suggested to be adopted in the
education of the child. Pleasure is, as much
as possible, to be associated with the early
lessons; but firmness, or, if need be, coercion
must be called in to confirm the habit of obe-
dience. Tyranny and cruelty will, in the horse,
more speedily excite a feeling of disobedience
even than in the child; and, on every possible
practicable occasion, a desire to resist the
power of command. The restive and vicious
horse is, in ninety-nine cases out of a hundred,
made so by ill-usage, and not by nature. None
but those who will take the trouble to try the
experiment, are aware how absolutely becomes
the control which the due admixture of firm-
ness and kindness will soon give him over any
horse. The breaker should keep in his mind
continually the Latin proverb, "quod factum
est bis factum est," what is well done, is twice
done.

Shying is very frequent among young horses;
and, where it appears, it should be particularly
attended to by the breaker-in. It arises from
several causes—namely, fear, roguery, want of
work, or defective vision. The more race-
blood a horse has, the less he is subject to this
infirmity or vice. The only remedy for it, is
to hold hard and keep quiet. As to the whip
and spur, and the silly checking a really fearful
animal with a sharp curb, as though the intent
were to break his jaw-bone, is an injudicious,
if not a cruel practice. Mr. Lawrence says—
"With affected shyers, some severity may be
necessary. 'Chaps' generally fix upon some
particular shying butt: for example, I recol-
lect having, at different periods, three hacks,
all very powerful; the one made choice of a
windmill for the object or butt, the other a
tilted waggan, and the last a pig led in a
string. I was once placed in a very danger-
ous predicament by this last, on a road filled
with carriages. It so happened, however, that
I rode the two former when amiss from a
violent cold, and they then paid no more
attention to either windmills or tilted waggon,
than to any other objects, convincing me that
their shying, when in health and spirits, was
pure affection. It is a thing seldom, per-
haps never, thought of or attended to, which
however detracts nothing from its conse-
quence, to accustom colts, during their break-
ing, to all the chief objects of their terror,
which may occasion the vice of shying. After
a colt shall have been a considerable time in
hand, and his education nearly finished, should
he be a careless and blundering goer, not suffi-
ciently bending his knees, he should be fre-
quently, but with great care, exercised daily
in a slow trot, over rough and uneven roads.

"To connect vices with their anomalies
together, I once had a fine hunting mare, an
incorrigible biter; as a proof of which, before
she came into my possession (but I was unap-
prised of it), she had killed a stable-boy; yet
her biting was entirely confined to the stable,
nor did she ever show either that or any other
kind of vice abroad, riding perfectly quiet."

These defects in the horse will be more fully
spoken of when we come to treat of his dan-
gerous habits or vices in another part of this
work. There also we will notice the power of
the Irish "whisperer," Sullivan, over the
animal; and notice Mr. Rarcy's mode, which,
in conjunction with the recent inventions of
Dr. Bunting, are likely, at no distant day, to supersede all the more antiquated systems of breaking-in.

CASTRATION.

The period at which this important operation may be best performed, depends much on the breed and form of the colt, and the purpose for which he is destined. For the common agricultural horse, the age of four or five months is the most proper time, or, at least, before he is weaned. Very few horses are lost when cut at that age. The operation should be performed when the weather is not too hot, nor the flies too numerous. We, however, enter our decided protest against the recommendation of valuable, but incautious agricultural writers, that "colts should be cut in the months of June or July, when flies pester the horses, and cause them to be continually moving about, and thereby prevent swelling." One moment's reflection will convince the reader that nothing can be more likely to produce inflammation, and consequent swelling and danger, than the torture of the flies hovering round, and stinging the sore part.

If the horse is designed either for the carriage or for heavy draught, the farmer should not think of castrating him until he is at least a twelvemonth old; and, even then, the colt should be carefully examined. If he is thin and spare about the neck and shoulders, and low in the withers, he will materially improve by remaining uncut another six months; but if his fore-quarters are fairly developed at the age of twelve months, the operation should not be delayed, lest he become heavy and gross before, and perhaps has begun too decidedly to have a will of his own. No specific age, then, can be fixed; but the castration should be performed rather late in the spring, or early in the autumn, when the air is temperate, and particularly when the weather is dry. No preparation is necessary for the sucking colt, but it may be prudent to bleed and to physic one of more advanced age. In the majority of cases, no after treatment will be necessary, except that the animal should be sheltered from intense heat, and more particularly from wet. In temperate weather he will do much better running in the field than nursed in a close and hot stable. The moderate exercise which he will take in grazing will be preferable to perfect inaction. A large and well-ventilated box, however, may be permitted.

The manner in which the operation is performed will be properly left to the veterinary surgeon. No common gelder should, now-a-days, be permitted to perform this operation. The old way of opening the bag, or scrotum, on either side, cutting off the testicles, and preventing bleeding or haemorrhage, by the temporary compression of the vessels while they are being seared with a hot iron, may not, perhaps, be entirely abandoned. There is at least an appearance of brutality, and, we believe, much unnecessary pain inflicted, when the spermatic cord—the vessels and the nerve—is tightly compressed between two pieces of wood, as in a powerful vice, and left there either until the testicles drop off, or is removed on the following day by the operator.

To the practice of some farmers, of twitching their colts at an early period, sometimes even so early as a month, there is stronger objection. When the operation of twitching is performed, a small cord is drawn as tightly as possible round the bag, between the testicles and the belly. The circulation is thus stopped, and, in a few days, the testicles and the bag drop off; but not until the animal has greatly suffered. It is occasionally necessary to tighten the cord on the second or third day, and inflammation and death have frequently ensued.

A new mode of performing this operation has recently been introduced—the operation by Lorison. It has the merit of apparently inflicting far less pain upon the animal, and entirely supersedes the brutal firing system. In performing it the scrotum is cut in the same manner as we have already described, and the vas deferens exposed and divided. A pair of forceps, made for the purpose, is then used to seize the artery, which is twisted half-a-dozen times round. As soon as the hold of the artery is relinquished, the coils are left untwisted, and the haemorrhage has ceased. The testicle is removed, and there is neither sloughing nor danger, neither of which is desirable.
CHAPTER VII.

RIDING: LEAPING.

RIDING.

In a treatise which has for its object a full description of the horse in every situation in which that noble animal is employed, it cannot be deemed out of place to devote a brief space to the equestrian art, to which, more especially, that quadruped was originally subjected. In our observations upon training the horse, we have not even alluded to what is called the grand menage, but we have strictly confined ourselves to that branch of breaking-in, which constitutes the proper education of the English horse for the field and the road. Accordingly, those animals which require a higher degree of perfection in the menage, whose business it is to teach horses to perform such feats as not only display their wonderful docility, tractability and agility; but their sagacity, as well as the entire subjection to which they have been reduced by the power of man. Therefore the horsemanship to which we shall here confine ourselves, will be restricted to that which is practised in the modern English school.

When the horse is led out, saddled and bridled, the next object of the rider ought to be to examine the state of the various equipments of his horse, and to ascertain that every part of them is strong, and has been so placed as to insure his own safety as well as the comfort of the animal he is to ride. The first object will be the bridle, to see that the headstall be of a proper length, neither too loose nor too short; as the curb-chain hooked in its proper place, leaving the snaffle above, and clear; the fore-top hair placed under the band of the bridle, and the reins untwisted and even.

The saddle should be put perfectly even and central on the back of the horse, so as not in the least to impede the motion of his shoulders; and the girths, buckled one over the other, sufficiently tight to retain the saddle firmly in its place. The real horseman inspects everything; he leaves nothing to chance. When a groom once knows that his horse has to undergo the critical examination of his master, it will have a tendency to make him careful in bringing the animal out in a perfect state.

Mr. Lawrence thus describes the next proceeding:—"The nag being led out and held, the jockey, that is to be, approaches the near left shoulder; and gathering up the reins between the fingers in his left hand, the thumb upwards, at the same time weaving his fingers into the mane of the horse, he acquires a hold fast and purchase. The whip is held with the reins, in the left hand. With his right hand he then takes hold of the stirrup, the flat side of the leather being placed towards him, and into the stirrup inserts his left foot. Next, placing his right hand on the cantle or after part of the saddle, and making a moderate spring or vault, being cautious, at the same time, to keep his foot and spur clear of the horse, he seats himself, and the left hand still retaining its hold of the mane, with the right he adjusts the stirrup to that foot. Being seated at his ease, as in a chair, and looking forward between the ears of his animal, he will find himself in a square and even position with him. The two forming a perfect centaur."

His next object is to adjust the reins, supposing them the bridoon or snaffle, and curb, which should be done by leaving the rein of the latter rather slack, the chief pressure being upon the snaffle rein; the curb he reserves for occasional use, when a more than ordinary command over the mouth of the horse may be necessary; the curb rein may then be drawn with the requisite force. The right foot being fixed in the stirrup, the whip, with its handle upwards, is gently withdrawn from the left to the right hand, and its usual place is down behind the calf of the leg. As to the seat, a man will sit upright, as in his chair; but in the common, and more particularly the sporting seat on horseback, the spine is bent in a
small degree outward, being directly contrary to the form in military equitation. The stirrup leathers should be of such length as to admit of the knee being sufficiently bent to retain a firm hold of the saddle; but not to that degree as to hoist the rider much above it when he stands in his stirrups. Nor should they be so long as to represent him as being a straight-kneed jockey, which detracts from his power on horseback, and is dangerous in respect to that pressure which has sometimes occasioned rupture in the belly of the rider. The foot, for the road or for sporting, indeed for the most secure seat, should be placed home in the stirrup, the toe rather elevated, and turned somewhat outward; thence arises a centre union of force between the foot and the knee, the toe being turned out, and the knee inward, pressing the saddle, which assures a firm seat. This is the very essence and groundwork of the seat in the speedy trot and gallop; and when to it are added the firm grasp of the thighs and the hold on the bridle, the stability of the seat is perfectly secured.

In military riding the seat is said to depend entirely on the equipoise, or balance, a point of consequence, no doubt, but which, on trying occasions, can only be maintained as above stated. It has been observed of bad horsemen that they can scarcely keep their spurs from the sides of their horses; but such can never be the case with the above seat, in which the greater difficulty is to reach their sides with the spurs. The act of spurring, contrary to the military mode, is performed with a kick, the toe being somewhat more turned out.

In dismounting, the left hand, inclosing the reins, resumes its former place in the mane, and the rider lands from the same side on which he mounted, with his horse safe in hand. Particular situations may render it necessary to mount on the off side. The convenience is considerable when the animal will stand still, unheld at the head, to be mounted; a point of obedience, however, to which some spirited and impatient horses can scarcely be reduced. When a horse is held for mounting, it should be by the checks of the bridle, not the reins, and least of all by the curb rein.

Being mounted, the rider may find the stirrup-leathers too long or too short. In applying the remedy the attendant should be careful to draw the buckle of the stirrup-leather to the top, and to leave the pad of the saddle smooth and even. The arms should hang easily down the waist, and, though the elbows are bent, they must not be awkwardly elevated or protruded. The bridle is held about level with, or rather above the pommel of the saddle, at a length somewhat beyond it, towards the rider. The reins should not be held so long and loose as to diminish the power of the rider in supporting the horse by a pull, in case of a false step. Few are left now of the school of Bakewell, who taught that the rider could afford his animal no possible support in case of stumbling, but that, by pulling at him, would rather accelerate his fall. The horse, well aware of the purpose for which he is mounted, will, in general, proceed, on his head being loosed; if not, an intimation, by gently moving the reins, or pressing his sides with the calves of the legs, will be sufficient. If a steady and quiet hack—and on such only a tyro should be mounted—he will commence with a walk, and, in all probability, continue that pace till put forward by his rider. Horses, indeed, full of good keep, high spirited, and having had little work, will, at starting, be impatient of a slow pace, and cut a few capers; on which the rider has nothing to do but to sit quiet with a mild and steady hand, until this merry fit is over. The proper starting pace, the walk, being continued at the rider's option, the intimations above described, or a gentle touch on the buttock with the whip or stick, will cause the animal to advance to his next pace, the slow or jog-trot—the best pace of the horse, perhaps, to those who ride for their health's sake, granting the motion be not too rough. In the walk, the slow trot, and the canter, the rider sits on his saddle as in his easy chair. In reference to the movement of the horse in the canter, Mr. Blaine says, "that the hind-legs are thrown in, and while elevated, the off fore-leg becomes raised from the ground, but the near fore-leg is not elevated until the hinder ones are replaced; and this constitutes the grand difference between the canter and the gallop. The sensation to the rider is as different as possible, and so is the action to the eye also. If this be established, it will call to mind that the whole
weight of the body must at one time rest completely on the near fore leg; and that this does take place in the center, is evident from the effects observed; for it is a remarkable fact, though seldom noticed by old writers, that in all cantering horses the near fore leg is more deteriorated, and exhibits more effects of work than the off. Judicious horsemen, sensible of this, do not therefore permit their horses always to lead on the same leg, but frequently change the centre, and gallop, canter, and trot sometimes with the right, and sometimes with the left shoulder forward.

The right foot is usually employed in the lead, when a horse is breaking-in as a 'canterer,' and it is proper so to commence the breaking-in. If the horse is awkward, or strikes off falsely, tighten the near rein, which, inclining his head to the left, naturally advances his right shoulder, and produces the disposition, when he is pressed forward by the hand, the whip, or the heels, to canter with the right shoulder forward. But we revert to our caution to avoid the continued use of the leading leg, which the reader may rest assured will suffer greatly, and become eventually contracted in the foot, gorged in the pastern, or lamed by splints. Some professed horsewomen use a screw-crutch for their saddle, by which they can shift their seat; and to those who ride a great deal, this is a very salutary custom, as the constant use of one posture has drawn the figure of the rider herself a little awry." In the speedy trot he makes more use of his knees, hitching, or his body rising or falling in unison with the motion of the horse. This motion of rising in the stirrups saves an immense amount of fatigue to the horse and unpleasantness to his rider. The Romans condemned the trot, and called it the crucifier or torturer. In the swift gallop the rider stands in his stirrups, chiefly depending on the grasp of his knees and thighs. Formerly it was the practice to ride a gallerop with stirrup-leathers too short, which made the seat unsteady, and too much dependence was placed for support on the reins. It is obviously impossible to lay down a precise rule in this case. The length at which to ride a racing-pace, whether trot or gallop, must be left to the judgment and convenience of the rider, with the remark that, of the extremes, riding too short is the worst. Rising in the trot, and lifting and working the horse along with the reins in the gallop by the jockey, are, no doubt, practices purely English.

Beyond the slow trot, the motion of few horses is sufficiently smooth and easy to encourage the rider to sit upon the saddle, nor is the appearance of such a seat very graceful. It is preferable then, if more speed in the trot be desired, to advance to that degree in which the rider may rise in his stirrups; in order to perform this easily and gracefully, the rate must be somewhat considerable. To put the animal into a canter, a touch of the left heel, and a gentle pull of the right rein, for which the right hand may be used, is the proper method.

Of the hand-gallop, with the right shoulder forward, Mr. Blaine says—"At the instant the horse elevates his fore quarters by means of the muscles of the loins, he throws his fore legs also forwards, through the agency of the muscles distributed to the shoulders and arms; but it appears that he does not elevate his fore limbs equally; the right is raised a little more, and it is likewise carried a little further forward than the left, which makes the action a pace not a leap. During this elevation, and in some instances preparatory to it, the right, or off hind foot, moves slightly forward, but only sufficient to gain a true centre, and to correspond with the increased forwardness of the right shoulder; the near hind leg, it must be remembered, yet remains fixed. The fore extremities now reach the ground, the near fore a little before its fellow, the off fore doubling over it and placing itself a little beyond it; and the slower the gallop, the more considerable will be the distance between the placing the fore legs. As soon as the near fore leg has met the ground, and before the off fore has yet taken its full bearing, the hinder legs are moved in the following manner:—the near hind elevates itself; and, as it reaches the ground, the off hind passes it and becomes placed also. It is now that the horse begins to be all in air in this pace; for on the next spring that the hind quarters make—the fore quarters being already elevated from the last impulse—the animal is, of necessity, completely detached from the ground. The next period when he is likewise so, is when the fore
quarters, meeting the ground, gain a new impulse by their rebound; the haunches are again thrown in to take their share in the support, and, also, to give their impelling power to the mass."

The simplest of all the paces of the horse is the full gallop. "Simple as it is, however," says the same eminent veterinary surgeon, "it cannot, in any instance, be commenced without the intervention of the slower gallop, in which one of the binder legs is first advanced to establish a new centre; for it would require too great an effort to raise the fore parts at once from a state of rest by means of the loins, and to throw them forwards at the first action to a considerable distance by means of the haunches and thighs. The fact is well known to jockeys and other sporting characters, and they often derive profit from the circumstance, by wagering with the unwary, that no horse shall be found to gallop one hundred yards while a man runs fifty, provided each start together; in which case so much time is lost in acquiring the due momentum, that the man has often won; make but the race for one hundred and fifty yards, and the horse would beat; for now the impetus being acquired, he arrives at sufficient momentum to overtake his antagonist. In the extended gallop, the fore parts, when raised, are forced forward by the alternate flexions and extensions of the angles of the hinder parts; and as both of the fore and both of the hind legs, in the racing gallop, become opposed to the ground in succession at the same moment—that is, as the two fore feet at once beat the ground together, and then the two hind, so it is evident that the gallop, if full, is nothing more than a repetition of leaps. Quickly as these leaps are repeated, yet the surface of ground passed over at each of them must necessarily be great to accomplish the pace at which the good racer goes. Hambletonian, in his match against Diamond, is said to have covered eighty-three-and-a-half feet of ground in a second; and by the calculations of M. St. Bel, Eclipse covered eighty-five feet of ground in the same time, when at the top of his speed. Every turf amateur must have remarked the horizontal position of the body in the racer at the momentous struggle. Every departure from a rectilinear form of the body would detract from the rapidity of its flight, and, therefore, even the head and neck are carried so as to fall within the line of the trunk. As a compensation, however, for the loss of the power sustained, the limbs are most extensively flexed, that the circles they form may be more extended."

On any critical occasion, whether arising from embarrassment on the road, or from unquietness in the horse, the reins may be taken separately in each hand; and this is much practised both in riding and driving. It obviously increases the power of the rider over his animal, and is useful in cases of starting and shying, or in any attempt to turn round, in plunging, kicking, or rearing. In the latter case, common sense will inform the rider, that he must lean forward with slack reins, or be may pull the horse over; certainly one of the most dangerous accidents among the many which appertain to equestrian art. Whilst leaning forward, he should apply his spurs sharply to the sides of the horse—a punishment which will cure him of this vice, granting it is curable.

In the opposite habit of kicking out behind, which some animals have the knack of doing very high, with jerks not very comfortable to the rider's back-bone, the precisely opposite course is to be adopted, to avoid a somersault over the shoulders of the horse. The rule now is—sit back, sit fast, pull hard, holding the head of the animal as high as possible, and spurring with force at every interval of kicking. Having the opportunity also, use the whip effectually on the thigh, the belly, and, if necessary, on the jaws. In a confirmed case of vice, nothing short of intimidation and absolute conquest will succeed. Such severity, indeed, instead of a cure, may sometimes produce desperation; and when patience and mild measures will succeed, they are infinitely preferable. We would always recommend that spurs be worn. With a restive horse they are indispensable; and in the case of being placed between two objects, one of which alarms him, and the other dangerous for him to come in contact with, the spur on the dangerous side is of unspeakable use, as constituting the principal dependence in aid of the hand of the rider to keep the horse in his safe and proper place.
Adams, an equestrian writer, says, the body must always be in a situation, not only to preserve its balance, but to maintain its seat. The distinction between the balance and the seat may be thus marked. The balance is the centrical or equilibrium position of the body, whatever may be the motion of the horse. The seat is the horseman's firm hold of the saddle, in situations where he might be liable to be thrown over the animal's neck, or to fall backwards over his tail.

To preserve the balance, it is evident the body of the rider must keep in the same direction as the horse's legs. For example, if the horse move straightly and uprightly on his legs, the body of the rider must be preserved in a position similarly upright; but if the horse bends or leans, as when running in a circle, or trotting round a corner, the rider must lean in the same direction, or his balance will be lost. The balance, indeed, may be preserved by a different seat; but the seat will not be secure.

Mr. Adams further remarks, that if the hand is held steady, as the horse advances in the trot, the fingers will feel, by the contraction and dilatation of the reins, a small sensation or tug, occasioned by the measure of every step. This, which is reciprocally felt in the horse's mouth, by means of the correspondence, is called the appui; and while the appui is preserved between the hand and the mouth, the animal is in perfect obedience to the rider, the hand directing him with the greatest ease, so that he seems to work by the will of the rider rather than the manipulative power. The hand then possesses, independently of other aids, more than sufficient strength to control and direct the horse that is broken and obedient.

Berenger furnishes us with five directions on the functions of the hand. They are these:

1. Hold your hand three fingers' breadth from your body, as high as your elbow, in such manner that the joint of your little finger be upon a right line with the tip of the elbow; let your wrist be sufficiently rounded, that your knuckles may be kept directly above the neck of the horse; let your nails be exactly opposite your body, the little finger nearer to it than the others; your thumb quite flat upon the reins, which you must separate by putting your little finger between them, the right rein lying upon it. This is the first and general position.

2. Does your horse go forward; or rather, would you have him go forward? If so, yield to him your hand; and for that purpose, turn your nails downward in such a manner as to bring your thumb near your body; remove your little finger from it, and bring it into the place where your knuckles were in the first position, keeping your nails directly above the neck of your animal.

3. If you would make your horse go backward, quit the first position, and let your wrist be quite round. Then allow your thumb to be in the place of the little finger in the second position, and the little finger in that of the thumb; turn your nails quite upward, and towards your face, and your knuckles will be towards your horse's neck.

4. If you would turn your horse to the right, leave the first position, and carry your nails to the right; then your hand upside down, in such a manner that your thumb be carried out to the left, and the little finger be brought to the right.

5. If you would turn to the left, quit again the first position; carry the back of your hand slightly to the left, so that the knuckles may come under a little, that the thumb may incline to the right, and the little finger to the left.

These different positions, however, adds Berenger, are, when taken singly, insufficient, unless the horseman be able to pass from the one to the other with readiness and order.

We have spoken of terrifying the vicious horse into subordination by severity; but a man of right feeling and reflection will always endeavour to render the labour of his animal as little irksome, and as comfortable to him as possible, and will, therefore, give him his rein, and bear as lightly on his mouth as may be consistent with such a hold upon him as the necessity of the emergency may require. If it appears we have laid much stress on the fixedness and grasp of the reins, we intended that grasp, like the curb of the bridle, to be only for occasional use; but by no means that the rider should be a mere fixture, as though nailed to the saddle. On the contrary, he should learn to sit at his ease, pliable to the motions of his horse, and in full possession of a just equi-poise.
In speaking of bridles, we should observe that the curb alone, and with single rein, is an unfair bridle, and entirely deceptive to the rider, since its first effect is to torture, and ultimately to harden the mouth of the animal, depriving it of that sensibility which is the basis of what we should call a good mouth. The curb, beside, is an awkward bit with which to effect the turn, it being only calculated for pulling straight forward. In former days the snaffle was deemed the severest bit, no doubt from its having been made small and sharp. Since then the snaffle has been changed into a mild bit, although hard and sharp snaffles still remain. Young horses should be first put to work with mild bits, and chiefly accustomed to the snaffle, which will ensure a good mouth, sufficiently hard for fair pulling, yet with a due share of sensibility and liability to be affected and acted on by the occasional use of the curb. The snaffle bit should be of considerable thickness, particularly at the ends next to the reins, and not made so long that the joint will work into the bars of the mouth. Many riders prefer a good snaffle-bridle horse to any other; still we think there is an additional convenience in the double-reined bridle, in case of a rein breaking.

In reference to the lady's horse, her pad should indicate considerable blood; and should rarely exceed fifteen hands in height; its paces should be rough; and the trot should be both slow and easy, which is the pace of health, and which is a valuable quality. The canter, however, is the principal requisite, which should be both natural and graceful; the neck handsomely curved, and the mouth possessed of a pleasant feeling. Whatever may be the natural beauties of such animals, however, the grand consideration is in the safety of their step; for a horse deficient in this respect, is perhaps, in his canter, always most liable to "kiss the ground." The most graceful canterers may be observed to lead generally with the off leg; but, no doubt, there is such an error as a horse, both in his canter and gallop, going with the wrong leg first, to the great uneasiness of the rider. This is more particularly felt on worn and battered horses, which change their legs to procure for themselves a momentary cessation from weakness, weariness, or pain.

The person who attends for the purpose of assisting a lady to mount her animal, should be close to her, join her hands, by placing his fingers within each other, to form a stirrup for her left foot, as near to the ground as possible. Her left knee must be quite straight, which will facilitate the assistant's effort to place her in the saddle—an act facilitated by a moderate spring from herself.

Some masters teach their lady pupils to ride on either side of the horse, and recommend the pommel of the saddle to be made very low, that the knee may not be thrown too high. They also recommend that the pommel be made with a screw, to be taken off in case of a lady wishing to change sides when she may desire it.

Ladies' riding-shoes should be always straight-soled, as, in case of accident, there is the risk of the foot hanging in the stirrup, when the sole, according to the old fashion, is hollow next the heel. A lady's pad should particularly be accustomed to walk off quietly; and with respect to his improvement in that pace, it is accomplished by touching him gently behind with the whip.

In case a lady should have to dismount with the assistance of only one person to hold her horse, steps or a chair are requisite. If there is not this convenience, she springs from her seat; and should her pad, which is so often the case, be upwards of fifteen hands, she may sometimes meet with a strained ankle, or some other accident. Having an assistant, she gives him her left hand, and holding herself by the crutch of the saddle, she alights. Her preliminary act, however, is gently to change her whip from the right to the left, or bridle hand, leaving its end to hang down the near shoulder of her pad, placing the reins upon the upright horn of the saddle, on which, also, she rests her right hand. Her garments clear of giving any obstruction, she may then, turning a little to the right, make her spring towards the assistant, who is ready to break her fall. She should be careful, on quitting the stirrup, to keep her knee upon the crutch, as a security in case of the horse starting. It is perhaps unnecessary to mention, that a gentleman who attends a lady on horseback, rides on her near side; and that it is one of his first duties, to keep himself between the lady and any
Equestrians, by Mr. Warde, a riding-master, we have the movements which occur in the standing-leap, very clearly and briefly described. "Let the rider," says this professor, "take up his horse at an animating pace; halt him with a tight hand upon his haunches; when rising at the leap, the rider should only just feel the reins, so as to prepare for slackening them when he springs forward, yielding them without reserve, as at the time the horse must be left quite at liberty. As the horse's hind feet come to the ground, the rider must again collect him, resume his usual position, and move on at the same pace, and his body must be inclined forward as the horse rises, and backwards as he alights."

In the flying-leap the horse must not be hurried, "but taken up at a brisk pace, with a light and steady hand, keeping his head perfectly steady and straight to the bar or fence. This position is the same as in the standing-leap; and the aids required are the same as for making a horse canter. If held too tight in the act of leaping, the horse is likely to overstrain himself and fall. If hurried at a leap, it may cause him to miss his distance, and spring too soon or too late; therefore his pace must be regulated, so that he may take his spring distant enough, and proportionate to its height, so that he may clear it. When nearing the leap, the rider must sit perfectly square, erect, pliant and easy in the act of leaping; on arriving at the opposite side of the leap, throw the body well back, and again have the horse well in hand."

We have spoken of the Irish horses as being excellent leapers; and in what is called the double leap, or back jump, their vast stretch is exemplified to an extraordinary extent. It is observed by Mr. Apperley, in vol. xi. of the Encyclopedia Brittanica, the power which some horses have of giving an additional impetus to their flight after they have left the ground in a leap. "After all," says he, "the most extraordinary fact relating to the leaping of horses, is the power they have of extending themselves, by a second spring as it were, when, on being suspended in the air, they perceive something on the further side of a fence for which they were not prepared. That they occasionally do this under good horsemen, all good horsemen of experience can vouch for;
but whence the fulcrum is derived, it would be
difficult to determine.”

In reference to this power in the horse, Mr.
Blaine is of the same opinion, and, indeed, cites
Mr. Apperley in support of it. The buck-leap
is not made when the horse is at the top of
his speed, but when at a trot, canter, or short
hand-gallop. Buck-leapers, however, are not
considered very safe, especially if there is
fatigue in the cases of the animals making
them. “The horse, in such a case,” says Mr.
Blaine, “not being able to bear the jar of a
secondary effort of the joints to relieve him-
self, the attempt often brings him down, and
thus it is that buck-leapers are seldom safe
ones. We would caution the nervous rider
against the dangerous custom which some have,
at every downward leap, of grasping the cantle
of the saddle with the whip-hand, for it not
only displaces the body, and, consequently,
unsteadies the seat, but it has likewise dislocated
the shoulder. We have seen others elevate
the whip-hand at every flying leap; and the
action appears to have become so natural to
them as not at all to discompose their seat.
In Ireland this is very common; and among
the regular ‘Pats,’ it is accompanied with a
voracious ‘hough,’ the rise of the hand and
voice being synchronous; neither is it impro-
bable that, from custom, both the action and
sound are inspiriting to the rider—perhaps to
the horse also.”

What are called the trial-leaps of the Irish
horses are, perhaps, the most extraordinary
instances of springing power that are to be
found in any country in the world. They are
taken over stone walls of six feet high, built
firm throughout by coping and dashing. When
Mr. Blaine was with his regiment in Ireland,
he had opportunities of witnessing some of
these daring feats. “Over these walls it was
a very common occurrence for their crack
fieldsmen to ride, but it was owned that some
of the stones were usually displaced in the
leap. Indeed, it was this very circumstance
that deprived the enterprise of half its danger.
A good horse there, when hunting, seldom
baulked such a leap; for he is aware that
either his knees or his breast will displace the
first tier of loose stone; the next rider who
follows does the same; and each one who
succeeds, is in more and more peril from the
loose stones, which very frequently give horse
and rider an awful somersault. That high
fencing-horses are almost, as it were, indigenous
to Ireland, we might conclude from the cir-
cumstance that, at one of the great horse fairs
held at Ballinasloe, the parish pound, which
is six feet in height, forms the trial-leap of the
high-priced horses bought there, each of which,
we are told, is expected to leap it ere the bar-
gain is concluded. It is also recorded of a
descendant of old Pot-8-os, from an Irish half-
bred mare, that she leaped a wall of seven feet
high, built for the purpose, in Phoenix Park,
Dublin.”

On the 24th of February, 1792, an Irish
bay horse, for the honour of Ireland, leapt
standing, the wall of Hyde Park, which was
six feet and a-half high on the inside, and
eight on the outside, where a long bed of
dung was laid to receive him on his descent.
This horse was the property of Mr. Bingham.
It was twice done by the same animal, which,
on the second leap, merely displaced a few
bricks. Steeple-chasers, of later years, are also
said to have achieved some extraordinary leaps.
Charity, winner of the Newport Pagnel Steeple-
Chase in 1841, cleared twenty-eight feet and
eighteen; and Peter Simple, at the Liverpool
Steeple-Chase, cleared the artificial water-cut,
opposite the Grand Stand, leaving his mea-
sured foot-prints thirty-two feet from bank to
bank.

We will conclude these feats of leaping by
giving a sustained instance of this power in the
horse; and which shows the wonderful stamina
possessed by some of the species. A match
was made between Sir Charles Turner and the
Earl of March, upon these conditions, that the
former should “ride ten miles within the hour,
in which he was to take forty leaps, each leap
to be one yard, one quarter, and seven inches
high.” The stake was 1,000 guineas, which
Sir Charles, with great ease, won upon a Gal-
loway, in thirty-six minutes.
CHAPTER VIII.

PURCHASING A HORSE; CHOOSING; EXAMINATION FOR DEFECTS AND DISEASE; JUDGING OF AGE BY THE TEETH.

REMARKS ON THE PURCHASING OF A HORSE.

Soundness in a horse is one of the first requisites in its purchase or sale; and there are few subjects upon which greater doubt, difficulty, and annoyance has arisen, than upon the condition and qualities of the animal that is about to pass from the hands of one master to those of another. There are few trades in which there is more deception practised than in the one pursued by the horse-dealer. "Beautiful as the animal is," says the editor of The Horse, "and identified as he is so much with our pleasure and our profit, he has been the object of almost universal regard; and there are few persons who do not pretend to be somewhat competent judges of his form, qualities, and worth. From the nobleman, with his numerous and valuable stud, to the meanest helper in the stable, and not excluding even the mechanic, who scarcely crosses, or sits behind a horse once in a twelvemonth, there is scarcely a man who would not be offended if he were thought to be altogether ignorant of horse-flesh. There is no subject on which he is so positive; there is no subject on which, generally speaking, he is so deficient; and there are few horses, on some points of which, these pretended and self-sufficient judges would not give a totally opposite opinion.

"The truth is, that this supposed knowledge is rarely founded on principle, or is the result of the slightest acquaintance with the actual structure of this animal, or that form and connexion of parts, on which strength, or fleetness, or stoutness, must necessarily depend. If we were constructing or examining a machine composed of levers and pulleys, and by which we purposed to raise a great weight, or to set in motion certain bodies with a given velocity, we should fail in our object, or expose our ignorance of the matter, if we were not aware what kind of lever, or connexion of levers was necessary, and in what situation the ropes should be placed, and in what direc-

tion the force should be applied, and by what means we could obtain mechanical advantage, and by what peculiar construction it would inevitably be lost."

These observations show to us the necessity of studying the anatomy of animals, before we have any pretensions to be critically acquainted with the cause of their powers. However, it will be sufficient for our general readers to lay down the commonly received opinions on points which constitute what may be considered an effective animal.

As everything in nature is adapted to some especial purpose, so has every horse its own particularity. Horses, however, not only differ in kind, but, like men, in utility, in temper, in stamina, they also differ. The selection of them, therefore, in regard to these particulars, constitutes one of the nicest duties of the judge or buyer, who must readily perceive good or bad conformation; trace genealogy in the outline, and discover their excellences and their opposites with readiness and certainty.

It requires some experience, but more attentive observation, to be what is termed, in equine phraseology, a good judge. To know at once, at a glance, whether the nag is likely to suit; whether he is cut out for a hackney, or is calculated for harness, is a power which only extensive observation and experience can give. Does he look like a hunter, or has he any good looks about him? Does he show any blood, or is he all over a mongrel? The man who knows these things, we should recommend to the uninitiated in the mysteries of horse-dealing, to make purchases for them.

At the risk of repeating ourselves a little, we must here generally describe the outward appearance of the horse again, in order to bring this more directly under the notice of the readers who may have the intention of purchasing one. In the first place, the head should be small. A large head is considered a bad point, inasmuch as it really, under certain circumstances, detracts from the powers of the
animal. He has, in fact, more to carry. It is
a burden to him; and the only way in which he
can possibly carry it to advantage, is at the
extremity of a short and upright neck. Next
to size, its shape becomes a consideration.
The forehead should be broad and flat, the
eye staring and full of fire; the ears thin, fine,
and often erect; the nostrils circular, dilated,
and reddened within; the lips soft, thin, and
hairless; the jowl extended, and the cheeks
well marked. This, at least, is what it should
be in the thorough-bred; and, as a general
rule, the nearer any other description of horse
approaches to this, the better is the family he
springs from, and the more sanguine we may
be in determining the extent, variety, and ex-
cellence of his qualities.

After the head comes the neck, which, if
good, will make the crest form an arch, or
agreeable curve, from the poll to the withers.
It will be of proportionate length, and will
progressively increase in breadth as it ap-
proaches the chest. A long neck, if it is
straight, or but little curved, is objectionable.
It has been said that short-necked horses are
better winded than others, because the air has
less distance to pass to and from the lungs;
but it is an opinion to which little deference
may be paid. The neck should be thin—at
least, not thick and heavy—and rounded and
straight along its lower margin. Should the
canal of the jugular vein be deep, and the
windpipe full and prominent below it, we may
regard it as a sign of good wind. If the arch
of the neck is reversed, i.e., below instead of
above, and the crest, or what ought to be the
crest, near the withers, is hollow and sunken,
the animal is, as we have before observed, said
to be "ewe-necked," which is one of the
greatest natural deformities common to these
parts. Under such circumstances, it is usual
for a dealer to say that "the neck is put on
the wrong side upwards;" but, in reality, it
appears to arise from its junction with the
chest being too low down.

Of all the points of a horse, the shoulder,
for a hackney or a hunter, is of the utmost
consequence. Without a good shoulder, no
animal can ride well. He may be a good
harness-horse, or he may race well, but it is
physically impossible for him to carry his rider
with ease and pleasure on the road. But how
are we to know what it is that constitutes a
good shoulder, and what it is that makes it
a bad one? To instruct the reader upon
these points, it will be necessary to say some-
thing on its internal mechanism. The scapulae
or shoulder-blades, are attached to the ribs by
many powerful muscles, which move them,
during the action of the animal, round their
own axes; or, at least, in a very similar way;
and though they can only revolve through the
small segment of a circle, that segment is
greater in proportion as they are more ob-
liquely placed against the sides of the chest;
hence it will be seen, what is called an
oblique shoulder, is most advantageous for
motion. It is said, that the best shouldered
animals have generally thin withers; but this
anatomical condition is not indispensably
necessary to the formation of a good shoulder,
although we are aware that there are some
judges of a contrary opinion. If, in viewing
the fore parts of a horse, we find he rises upon
the withers, and that no traces of his blade-
bone can be seen under the skin, but that all
appears smooth and level, we may conclude
that the shoulder is oblique. A more certain
proof of this, however, will be found by carry-
ing the eye from the top of the withers to the
extremity of the point of the shoulder. If it
is upright, or nearly so, unless it be in a
thorough-bred horse, such an animal is only
fit for the collar. That horses have been fast
runners on the turf with bad shoulders, is no
proof that they would not have galloped
better with good ones; and we must recollect,
that, in a racer, the hind quarters are con-
sidered of primary importance. On the road,
however, we know that bad shouldered animals
are neither pleasant nor safe hackneys. They
step short; are paddling walkers; roll about
in the trot, and are exceedingly liable to fall.
The fore legs, when viewed laterally, should
descend in a straight line from the bottom of
the shoulder; but when seen in front, they
ought to incline gently inwards. If the elbow
projects directly backwards, and the toe points
with precision forwards, we may rest satisfied
that the horse is not twisted in his fore legs.
Turning the toe in or out in standing, is apt
to be accompanied with distortion, or de-
formity of the limb. This circumstance,
therefore, is seldom seen without materially
lessening the value of a horse. Of the two faults, turning them out is the greater; for the pointing inwards is seldom carried to extreme. A good arm is broad and thick; long, when compared to the leg, and marked exteriorly by muscular prominences. The elbow cannot project too far back; and the more plump the muscle is immediately above it, we may conclude that so much the greater are the powers of the animal.

The knees ought to be large, broad in front, and distinctly marked with several bony knobs; lateral thickness is also of much importance. When the radius—the bone of the arm—instead of descending in a straight line, is directed backwards, so that the knee appears to recede from it, the horse is said to be calf-kneed, a term which expressly conveys the idea we have of this formation, which is always objectionable for the saddle, though it may do for the coilair. The leg should fall in exactly perpendicular from the carcase, and be short when compared with the arm—the converse of this being indicative of weakness—and of sufficient breadth to enable a purchaser, even at a distance, to distinguish the tendons and bone, with perfect clearness in their relative situations. If this cannot be done, there is reason to suspect that he is what is called gummy—an effect produced by hard or premature work, for it is never a natural defect. Should the legs be round and straight below, they are called stilty, and are never firm and good; but the best, and only correct way to judge of these members, is to pass the hand down them. If they measure much round, and the sinews feel firm, hard, and distinct, like well-braced cords; and if the intervening spaces between bone and sinew are clean—free from gum—we may pronounce them good.

The fetlocks, as a joint, should be of large dimensions, in proportion to the other parts. No joint, in fact, is too large, provided its bony prominences are seen with the naked eye, and its ligaments perfectly perceptible to the touch of our fingers. Knuckling over in the fetlock is a sign of either original mal-formation, such as uprightness in the pasterns, or else is the result of hard work; and the tottering affection of the limb, accompanying this state, is caused by local debility, and excessive irritability in the nervous system. The pasterns always deserve the attention of the buyer: when good, their length is in proportion to that of other parts; and they should have a considerable oblique inclination downwards and forwards to the foot. Horses with very oblique pasterns, are likely to break down; and, for this reason, they should never be shod with thin-heeled shoes. On the other hand, if they are very short and upright in these joints, they are seldom or ever sure-footed, and will, from work, soon become stilty or groggy.

The hoof is the next point to be considered, and we cannot be too careful in its examination. “No foot, no horse,” is a trite, but very true saying. First, we should look to its size. A small foot is not only objectionable in itself, even though it be a natural formation, but is often a characteristic of disease; and a small and upright hoof is a morbid feature in a horse. White hoofs are to be viewed with suspicion, for they are really weaker, and more liable to disease than black ones; and if an animal has one white, and the other dark, and he is lame, in nine cases out of ten, it will be found that the halting arises from some affection in the white hoof. It must be observed, too, that the natural form of the hoof is not destroyed by narrowness at the heels. A good hoof is circular in the tread, or nearly so, measuring as much from side to side as from toe to heel: but it is frequently found that hoofs that are morbid, measure as much from toe to heel as twice the lateral diameter. On the other hand, the wall of the hoof, which should, at all times, be perfectly smooth and free from ridges—the contrary indicating disease—may be very oblique; in which case it is not only circular, but spreads out, in the tread, to such a degree as enables a judge at once to pronounce it in a state of morbidity. Large horses, bred in low marshy situations, are most subject to this kind of foot; and the strong and upright foot is likely to become contracted; so is this one subject to a disease called fleshly soles. Indeed, in the former, the sole is concave; but, in the latter, it is flat, on which account different modes of shoeing are necessary, in order to meet the requirements of each case.

In speaking of the body or carcase, it may be subdivided into the chest, the belly, and the loins. So far as regards the constitution of the horse, his stamina, or his bottom, no part
is of more consequence than the chest; but like that of many other parts, no particular construction of it is, for all sorts of animals, the best. The chest of the cart-horse should be circular, broad in the bosom, and large in the girth; that of the thorough-bred, more circumscribed, but not flat-sided, very deep, and also extensive in the girth; so that the two differ more in width than in depth. A full and prominent breast is a fine point; and the ribs should stand out with sufficient curve to afford space enough within. For this reason some prefer a shoulder of middling thickness, if it is an oblique one; because, besides the one mentioned, it has another advantage—of enabling the rider to feel that he has something substantial under him. A narrow-caredosed horse is always exceptional, for he is commonly an indifferent feeder. If we expect durability in a horse, the barrel should be round, and capacious enough to give room for the heart and lungs to play. This organisation is essential to those animals from which hard work is daily expected. The opposites of this form are generally of weak constitution, although they may give sufficient satisfaction to those riders who merely use them for summer recreation. They are generally what is termed 'wasty,' parting with their food too quickly, and perfectly incompetent to perform any great labour, or endure continued hard work.

The back should be perfectly straight, as one that is hollow indicates want of strength, although such a form is often extremely pleasant to the rider. A reach back, the reverse of a hollow back, is by no means handsome, but it is stronger. One objection to it, however, is, that it is apt to chafe from the saddle. The loins are a point which merit the most particular attention. A hollow back and a narrow loin are generally indicative of natural weakness; but the latter is far more exceptionable than the former. A horse so formed can seldom carry much weight, is easily knocked up, and often proves a bad feeder. His constant hollowness in the flank, and his lack appearance altogether, after a day's hunting, amply demonstrate his utter incapability of sustaining the great exertion necessary to the satisfactory performance of his situation.

The manner in which the tail is set on must not be overlooked. A horse that carries two good ends—of which the head forms one, and the tail the other—always looks grand and showy. Above all others of his species, the charger should possess these points in perfection, to coincide with the grandeur of his carriage in the ostentatious parade of a field-day. In most horses this posterior appendage should form, when elevated, a straight line, or nearly so, with the back. A gentle declivity of the croup, however, from the summit of the rump, denotes the blood-like quarter, and adds much grace to this part in the thorough-bred animal. Should this line, however, decline very much, the quarters lose much of their beauty as well as their natural power. Nothing is so ugly, in a full-quartered horse, as to see the tail set on low down, and, as it were, springing abruptly from the rump. The dealers fit all horses indiscriminately; but this is certainly injudicious, for it subjects those which naturally carry good tails, to the same suspicion as it does those which may be really figgled to answer the purposes of the dealer. Fiery and spirited hackneys seldom require nicking; and hackneys are often called cock-tails, in contradistinction to those that are thorough-bred, which never carry any but a drooping tail. A cocked-tail is incompatible with a blood-quarter; hence blood-horses should never be figgled or nicked.

The quarters may be full, small, or fine and blood-like. Full quarters are such as are possessed by cart-horses, large machines, and hackneys able to carry weight. These animals are wide in the hips, though these are but indistinctly marked, in consequence of being enveloped by large, coarse, and flabby muscles. People are too apt to regard wide hips as an objectionable point, from their giving to the horse the appearance which is called ragged, and which is produced by a bad loin, and lean, flat, and weak quarters. Were these parts well formed, the hips might be pronounced the best description. The small quarter is one that is often seen in a horse of this form; and though its general contour may be regular and uniform, it is altogether disproportionately small when compared with the carcass. If it grows narrow towards the hinder part, the animal is said to be goose-rumped.

Of all other structures, the blood-like quarter is the best adapted for speed. In the blood-horse the tail is set on high up, and the
MUSCLES of the HORSE.
Hips are lofty and prominent, but not ragged; so that many of our best racers are higher behind than before; the spaces between them and the points of the quarters great, as are also those between the latter parts and the stiles. The haunches want the plump and round appearance of the full quarter; but so far from either being lank or thin, they are striped with bold and prominent muscles, free from the adipose and cellular substance which constitutes the flabbiness of those with full quarters, and are so distinct, that even through the skin, we can distinguish where one ends and another begins. The stiles should project boldly forwards, and have a perceptible irregularity of surface. Thighs, when long, thick, and muscular, are pronounced to be "good." The hock, of all other parts in the racer, is of the utmost importance; it should be broad, flat, and of large dimensions. The propulsion of the animal machine is effected chiefly by those muscles which are attached to the point of the hock; so that the more this projects, the greater the force these can exert, simply on the principle of the lever.

The half-bred horse, with good hocks, possesses the same advantage in hunting as the racer does on the turf. The point of the hock, as we have before observed, cannot stand out too much; indeed, the greater its dimensions altogether, the better, provided it be not gummy, or that its various bony projections and sinewy parts are distinctly seen or felt. If the hock is narrow, its point round and not well defined, it is said to be straight; and, from its being liable to curbs, is called a curby hock. Should its point be directed inwards, and the toes turned outwards, the horse is said to be cow-hocked, or cat-hammed. As this is a part very liable to disease, as well as to original mal-formation, the nicest examination is required to detect all that may prove disadvantageous or injurious to its function, the proper performance of which is of so much importance, that the propulsion of the whole machine depends chiefly upon it.

In spite of the old adage, "that a good horse is never of a bad colour;" still colour is, by many persons, esteemed of considerable importance. Bays and browns are considered, generally, good colours, as they are almost invariably accompanied by black legs, and, as a consequence, good black hoofs, which are always preferable to white ones. Chestnut colours and roans are much approved of. The dark iron-grey is often a colour sought after; yet, horses of this colour, as they advance in years, gradually become lighter; and, at the age of eight or nine, will be nearly white. Grooms have an objection to this colour, and with some justice; for the animals stain themselves so frequently by even lying down, that it is almost impossible to keep them clean without washing them, and this renders them liable to take cold. There is also an objection, generally, to the natural softness of their hoofs, a circumstance which makes it difficult to shoe them firmly and well.

Such, generally speaking, may be considered the essential properties of an effective animal; and what constitutes sometimes its opposite we will now consider more particularly.

The editor of The Horse says—"That horse is sound in which there is no disease, nor any alteration of structure in any part which impairs, or is likely to impair his natural usefulness. That horse is unsound that labours under disease, or that has some alteration of structure that does interfere, or is likely to interfere with his natural usefulness. One horse may possess great speed, but is soon knocked up; another will work all day, but cannot be got beyond a sniff's pace: one with a heavy forehead is liable to stumble, and is continually putting to hazard the neck of his rider; another, with an irritable disposition and a washy make, loses his appetite, and begins to secur if a little extra work is exacted from him. The term unsoundness cannot be applied to either of these; it would be opening a door to endless wrangling. The buyer can discern, or ought to know, whether the form of the horse is that which will render him likely to suit his purpose; and he should try him sufficiently to ascertain his natural strength, endurance, and manner of going. Unsoundness, we repeat, has reference only to disease, or to that alteration of structure which is connected with, or will produce disease, and lessen the usefulness of the animal."

These principles will be best illustrated by a brief consideration of the usual supposed causes of unsoundness.

Broken-knees certainly do not constitute
unsoundness after the wounds are healed, unless they interfere with the action of the joint; for the horse may have fallen from mere accident, or through the fault of the rider, and received no injury beyond the blemish. No person, however, will buy a horse with broken knees unless he has thoroughly tried him, and satisfied himself as to his form and action.

_Capped Hocks_ may be produced by lying on an unevenly paved stable, with a scanty supply of litter, or by the habitual vice of kicking. In neither of these cases, however, would they constitute unsoundness, although in the latter they would be an indication of vice; but, in the majority of instances, they are the consequence of sprain of the hock; and, when accompanied by enlargement, constitute unsoundness. A special warranty should always be taken against capped hocks.

_Contraction_ is a considerable deviation from the natural form of the foot; but not necessarily constituting unsoundness. It requires, however, a most careful examination on the part of the purchaser or veterinary surgeon, to ascertain that there is no heat about the quarter, or ossification of the cartilage; that the frog, although diminished in size, is not diseased; that the horse does not step short, and go as if the foot were tender; and that there is not the slightest trace of lameness. Unless these circumstances, or some of them, are detected, a horse must not be pronounced to be unsound because his feet are contracted; for many horses possessed of feet singularly contracted, are perfectly free from lameness. A special warranty, however, should be required where the feet are at all contracted.

_Corns_ manifestly constitute unsoundness. The portion of the foot in which they are situated will not bear the ordinary pressure of the shoe; and any accidental additional pressure, emanating from the growing down of the horn, or the introduction of dirt or gravel, will cause serious lameness. They render it necessary to wear a thick and heavy shoe, or a bar shoe, for the purpose of protecting the weakened and diseased part; and they are very seldom radically cured. They are usually found in white feet with weak low heels; but they are too common in feet of all colours.

_Cough._ This is a disease, and consequently unsoundness. However slight may be its degree, and of whatever short standing it may be, although it may sometimes scarcely seem to interfere with the usefulness of the horse, yet a change of stabling, or slight exposure to wet and cold, or the least over-exertion, may at other times cause it to degenerate into many dangerous complaints. A horse, therefore, should never be purchased with a cough upon him without a special warranty; or if—the cough not being observed—he is purchased under a general warranty, that warranty is thereby broken.

It is not law, however, that a horse may be returned on breach of the warranty. Unless the seller of the horse has contracted to take him back, he is not necessarily bound to do so. He is liable in damages, however. Lord Ellenborough says—"I have always held that a warranty of soundness is broken, if the animal, at the time of the sale, had any infirmity upon him that rendered him less fit for present service. It is not necessary that the disorder should be permanent or incurable. While he has a cough he is unsound, although that may either be temporary or prove mortal." In giving judgment upon another case, the same authority said—"I have always held it, that a cough is a breach of the warranty. On that understanding I have always acted, and think it quite clear." According to this judge, therefore, cough is a breach of warranty.

_Roaring, Wheezing, Whistling, High-blowing, and Grunting_, being the result of alteration of structure or disease in some of the air passages, and interfering with the perfect freedom of breathing, and especially when the horse is put on his speed, without doubt constitute unsoundness. There are decisions to the contrary, which are now universally admitted to be erroneous. Broken wind is still decidedly unsoundness.

_Crib-biting._ Although there is some difference of opinion on this point, nevertheless crib-biting must be regarded as unsoundness. This unnatural sucking in of the air must, to a certain degree, be detrimental to digestion, dispose to colic, and interfere with the strength, usefulness, and health of the horse. Some crib-biters are good goers; but they probably would have possessed more endurance had they not acquired this habit; and it is a well-
established fact, that as soon as a horse becomes a crib-biter, he, in more than nine cases out of ten, begins to lose condition. He is not, to the experienced eye, the same animal he was before. It may not lead to absolute disease, or it may rarely do so to any considerable degree; but a horse that is deficient in condition, must, to that extent, have his capability for extraordinary work diminished, although not so often as to be apparent in ordinary work; and so far, the horse is unsound. Although the habit may have had its origin in a mere trick, yet, when it has become confirmed, the animal is greatly deteriorated by it.

The wear of the front teeth, and even the frequent breaking of them, make a horse old before his time, and sometimes render it difficult, or almost impossible, for him to graze, when his state or the convenience of the owner requires that he should be turned out.

Curb constitutes unsoundness while it lasts, and perhaps while the swelling remains, although the inflammation may have subsided; for a horse that has once thrown out a curb, is, for a while at least, very liable to do so again on the slightest extra exertion. A horse, however, is not returnable, although he should spring a curb five minutes after the purchase; for it is done in a moment, and does not necessarily indicate any previous unsoundness or weakness of the part.

Cutting, as rendering a horse liable to serious injury of the legs, and indicating that he is either weak, or has an awkwardness of gait inconsistent with safety, is rather productive of unsoundness than is unsoundness itself. Many horses go lame for a considerable period after cutting themselves severely; and others have dropped from the sudden agony, and endangered themselves and their riders. As some doubt, however, exists on this subject, and as it is a very material objection to a horse, cutting, when evident, should have its serious consequences provided against by a special warranty.

Enlarged Glands. The enlargement of the glands under the jaw has not been so much considered as it ought, in an estimate of the soundness of the horse. Simple catarrh will occasionally, and severe affection of the chest will generally, be accompanied by swelling of these glands, which does not subside for a con-
siderable time after the cold or fever has apparently been cured. To slight enlargements of the glands under the jaw much attention need not be paid; but if they are of considerable size, and especially if they are tender, and the glands at the root of the ear participate in the enlargement, and if the membrane of the nose is redder than it should be, we should hesitate in pronouncing that horse to be sound.

The tumidity must, in our opinion, be considered as a symptom of disease.

Enlarged Hock. A horse with enlarged hock is unsound. The structure of this complicated joint being so materially affected, that although the animal may appear for a considerable time to have the capacity of doing ordinary work, he will occasionally fail even in that, and a few days' hard work will always lame him.

The Eyes. That inflammation of the eye of the horse which usually terminates in blindness of one or both eyes, has the peculiar character of remitting or disappearing for a time, once or twice, before it fully runs its course. The eye, after an attack of inflammation, regains so nearly its former natural brilliancy, that any one even well acquainted with horses will not always recognise the traces of former disease. After a time, however, the inflammation returns, and the result is decisive.

As the horse is being led out of the stable into the light, his manner and action should be closely observed. If he turns his ears so as to catch whatever noises may be coming from different directions, lifting his feet unusually high, hanging back on the halter, and apparently taking every step with caution, suspicion should at once be awakened that all is not right with his eyes. When the animal is given to start, it is, by many, considered a sign of some degree of defective vision. There is one cause of blindness by which the initiated buyer may be readily deceived: this is in the case of Cutta Serena, or paralysis in the optic nerve. "In this irremediable affection," says the author of The Horse, "the textures of the eye appear natural and unimpaired. There is no apparent alteration of structures, no cloudiness, no opacity; the only indication being the large and unmoveable state of the pupils, which remain equally distended in the dusk of evening and the glare of the noon-day sun."

If a man buys a horse actually blind, he will
certainly repent of his bargain, but he cannot get rid of it. He must therefore be careful, as the law will not protect him if he does not use common prudence.

Lameness, from whatever cause arising, is unsoundness. However temporary it may be, or however obscure, it lessens the utility of the horse, and renders him unsound for the time. How far his soundness may be afterwards affected, must depend on the circumstances of the case. A lame horse is for the time an unsound one.

Lord Ellenborough, in the case of Eldon v. Brogden, says—"I have always held, and now hold, that a warranty of soundness is broken if the animal, at the time of sale, has an infirmity upon him which renders him less fit for present service. It is not necessary that the disorder should be permanent or incurable. While a horse has a cough he is unsound; although it may either be temporary or may prove mortal. The horse in question having been lame at the time of sale, when he was warranted to be sound, his condition subsequently is no defence to the action." This judgment is confirmed by the decision of Mr. Baron Parke; but lawyers, as well as doctors, sometimes differ in their judgments. Chief Justice Eyre says—"A horse labouring under a temporary hurt, which is capable of being speedily cured or removed, is not an unsound horse; and where a warranty is made that such a horse is sound, it is made without any view to such an injury; nor is a horse so circumstances within the meaning of the warranty. To vitiate the warranty, the injury the horse has sustained, or the malady under which he laboured, ought to be of a permanent nature, and not such as may arise from a temporary injury or accident."

Neurotomy. A question has arisen how far a horse that has undergone the operation of the division of the nerve of the leg, and has recovered from the lameness with which he was before affected, and stands his work well, may be considered to be sound. It was the opinion of Chief Justice Best that such a horse was unsound; and, in our opinion, there cannot be a doubt about the matter. An animal on which this operation has been performed may be improved; may cease to be lame, may go well for many years; but there is no certainty of his continuing to do so; and he is unsound.

Puniced-foot. When the union between the horny and sensible lamina, or little plates of the foot, is weakened, and the coffin-bone is let down, and presses upon the sole, and the sole yields to this unnatural weight, becomes rounded, and is brought in contact with the ground, and gets bruised and injured, that horse must be unsound, and unsound for ever, because there are no means by which we can replace the coffin-bone in its original situation.

Lateral Cartilages. When these become ossified, it almost invariably causes lameness, and constitutes unsoundness.

Quidding. If the mastication of the food gives pain to the animal, in consequence of soreness of the mouth or throat, he will drop it before it is perfectly chewed. This, as an indication of disease, constitutes unsoundness. Quidding sometimes arises from irregularity in the teeth, which wound the cheek with their sharp edges; or a protruding tooth renders it impossible for the horse to close his jaws so as to chew his food thoroughly. Quidding is unsoundness for the time; but the unsoundness will cease when the teeth are properly filed, or the soreness relieved, or the cause of the imperfect chewing removed.

Quitter is unsoundness.

Ring-bone. Although when the bony tumour is small, and on one side only, there is little or no lameness, yet there are a few instances in which a horse with ring-bone has worked for many years without lameness. From the action of the foot, and the stress upon the part, the inflammation and the formation of bone contract a tendency to spread so rapidly, that we must pronounce the slightest enlargement of the pastern, or around the coronet, to be a cause of unsoundness.

Sandcrack is manifestly unsoundness. It may occur without the slightest warning; and no horse can be returned for the appearance of one that is sprung after purchase. The usual cause of this disease is too great brittleness of the crust of the hoof; but there is no infallible method of detecting this, or the degree in which it must exist, to constitute unsoundness. When the horn round the bottom of the foot has chipped off so much that only a skilful smith can fasten the shoe without pricking the
horse, or even when there is a disposition in
the bone to chip and break off in a much less
degree than this, the animal may probably be
returned as unsound; for this brittleness of the
crust is a disease of the part, or it is such an
altered structure of it as to interfere materially
with the usefulness of the horse.

_Sprain_ is unsoundness, whether the bony or
the blood-sprain. In the first, lameness is pro-
duced, at least at starting, in ninety-nine cases
out of a hundred; and there is enlargement of
the hock, which rapidly spreads with quick and
hard work, although the horse may be capable
of, and may even get better at slow work. If
there is no lameness, still a spained horse
should be rejected, because the bony enlarge-
ment is too near a very important and complic-
ated joint, and on the least injury or sprain
of that joint, would spread over it, and materi-
ally interfere with its motion.

_Bog or Blood-sprain_ is unsoundness, be-
cause, although it may not be productive of
lameness at slow work, the rapid and powerful
action of the hock in quicker motion will pro-
duce permanent, although not considerable
lameness, which can hardly ever be with cer-
tainty removed.

_Splint._ It depends entirely on the situation
of the bony tumour on the inside of the shank-
bone, whether it is to be considered as un-
soundness. If it is not in the neighbourhood
of any joint, so as to interfere with its action,
and if it does not press upon any ligament or
tendon, it may be no cause of unsoundness,
although it is often very disagreeable to look
upon. It does not lessen the capability and
value of the animal.

_Stringsalt._ This singular and very un-
pleasant action of the hind leg must be deter-
mined as a sign of unsoundness. It is an
irregular communication of nervous energy to
some muscle of the thigh, observable when the
horse first comes from the stable, and gradu-
ally ceasing on exercise. It has usually been found
in those horses that have a more than common
degree of strength and endurance; but, how-
ever this may be, it must be set down in the
catalogue of those morbific affections which
more or less deteriorate the qualities of the
horse.

_Thickening of the back sinew._ Sufficient
attention is not always paid to the fineness of
the legs of the horse. If the flexor tendons
have been sprained so as to produce consi-
derable thickening of the cellular substance
in which their sheaths are enveloped, they
will long afterwards, or perhaps always, be
liable to sprain from causes by which they
would otherwise be scarcely affected. The
continuance of any considerable thickness
around the sheaths of the tendons, indicates
previous and violent sprain. This very thick-
ening will fetter the action of the tendons; and
after much quick work, will, from the very
friction, occasionally renew the inflammation
and the lameness; therefore, such a horse
cannot be sound. It requires, however, a little
discrimination to distinguish this from the
_gumminess_ or roundness of leg, peculiar to
some breeds. There should be an evident
difference between the injured leg and the
others.

_Thoroughpin_, except it is of great size, is
rarely productive of lameness, and therefore,
when unaccompanied by any such appearance,
cannot be termed unsoundness. As it is the
consequence of hard work, and now and then
does produce lameness, the hock should be
most carefully examined, and there should be
a special warranty against it.

_Thrush._ There are various cases on record
of actions having been raised because of the
thrust in horses, and the decisions have been
much at variance, or perfectly contradictory.
Thrush has not always been considered by
legal authority as unsoundness. We, how-
ever, consider that it is so. This disease con-
ists of a discharge of fetid matter from the
frog, accompanied with considerable tender-
ness of the part, and sometimes of the whole
foot. It is not unfrequently brought on by
the horse standing in the stable without exer-
cise; but it is most commonly caused by the
negligence of the groom allowing the frog to
become rotten from the filth of the stable.

_Winggalls._ There are few horses perfectly
free from winggalls, but they do not interfere
with the action of the fetlock, or cause lame-
ess, except when they are numerous or large.
They constitute unsoundness only when they
cause lameness, or are so large and numerous
as to render it likely that they will cause it.

In the purchase of a horse the buyer
usually receives, embodied in the receipt, what

163
is termed a warranty. It should be thus expressed:—

"Received of A. B. forty pounds for a grey mare, warranted only five years old, sound, free from vice, and quiet to ride and drive.

"£40."

C. D."

A receipt including merely the word "warranted," extends only to soundness: "warranted sound" extends no further. The age, freedom from vice, and quietness to ride and drive, should be especially named. This warranty embraces every cause of unsoundness that can be detected, or that lurks in the constitution at the time of sale, and to every vicious habit which the animal has hitherto shown. To establish a breach of the warranty, and to be enabled to return the horse, or recover the price, the purchaser must prove that he was unsound or viciously disposed at the time of sale. In cases of cough, the horse must have been heard to cough previous to the purchase, or as he was led home, or as soon as he had entered the stable of the purchaser. Coughing, even on the following morning, will not be sufficient; for it is possible that he might have caught cold by change of stabling. If he is lame, it must be proved to have arisen from a cause that could not have occurred after the animal was in the possession of the purchaser. "No price will imply a warranty," or be equivalent to one; there must be an express warranty. A fraud must be proved, in the seller, in order that the buyer may be enabled to return the horse or maintain an action for the price. The warranty should be given at the time of sale. A warranty, or a promise to warrant the horse, given at any period antecedent to the sale, is invalid; for the horse is a very perishable commodity, and his constitution and his usefulness may undergo a considerable change within the compass of a few days. A warranty after the sale is invalid, for it is given without any legal consideration. In order to complete the purchase there must be a transfer of the animal, or a memorandum of agreement, or the payment of earnest-money. The least sum will suffice for earnest. No verbal promise to buy or to sell is binding without one of these. The moment either of these is effected, the legal transfer of property or delivery is made; and whatever may happen to the animal, the seller retains or is entitled to the money. If the purchaser exercises any act of ownership, by using the horse without leave of the vendor, or by having any operation performed, or medicines given to him, he thereby makes him his own. The warranty of a servant, we believe, is considered to be binding on the master, notwithstanding that Lord Kenyon had some doubt on this subject.

If the horse should be afterwards discovered to have been unsound at the time of warranty, the buyer may tender a return of it; and if it is not taken, may raise an action for the price. The vendor, however, is not bound to annul the contract, unless he had so agreed to do. Although not legally compelled to give notice to the seller, of the discovered unsoundness, it will be better for it to be done. The animal should then be tendered at the house or stables of the vendor. If he refuse to receive him, the animal may then be sent to a livery stable and sold. After this, an action—the horse having been tendered—may be brought for expenses, as well as for price. The keep, however, can be recovered only for the time that necessarily intervened between the tender and the determination of the action. It is not legally necessary to tender or return the horse as soon as the unsoundness is discovered. The animal may be kept for a reasonable time afterwards, and even proper medical means used to remove the unsoundness; but courtesy, and indeed justice, will require that the notice should be given as soon as possible. Although it is stated, on the authority of Lord Loughborough, that "no length of time elapsed after the sale will alter the nature of a contract originally false;" yet there are cases on record in which the plaintiff was nonsuited because he did not give notice of the unsoundness in a reasonable time. The extent of this reasonable time must depend on many circumstances.

It used to be supposed that the buyer had no right to have the horse medically treated, and that he would vitiate the warranty by doing so. The question, however, would be, has he injured or diminished the value of the animal by so doing? It will generally be prudent for him to refrain from all medical treatment, because the means adopted, however skilfully employed, may have an unfortunate effect, or may be misrepresented.
The purchaser, possibly, may like the horse, notwithstanding his discovered defect, and he may retain and bring his action for the depreciation in value on account of the unsoundness. Few, however, will do this, because the retention of the horse will cause a suspicion that the defect was of no great consequence, and will give rise to much cavil about the amount of damages; and, after all, very slight damages will probably be obtained.

Upon this point Lord Eldon says—"I take it to be clear law, that if a person purchases a horse that is warranted, and it afterwards turns out that the horse was unsound at the time of the warranty, the buyer may, if he pleases, keep the horse, and bring an action on the warranty, in which he will have a right to recover the difference between the value of a sound horse and one with such defects as existed at the time of warranty, or he may return the horse, and bring an action to return the full money paid; but, in the latter case, the seller has a right to expect that the horse shall be returned to him in the same state in which he was when sold, and not by any means diminished in value; for, if a person keeps a warranted article for any length of time after discovering its defects, and, when he returns it, it is in a worse state than it would have been if returned immediately after such a discovery, I think the party can have no defence to an action for the price of the animal on the ground of non-compliance with the warranty, but must be left to his action on the warranty to recover the difference in the value of the article warranted, and its value when sold."

Where there is no warranty an action may be brought on the ground of fraud; but this is very difficult to be maintained, and few possibly will hazard it. It will be necessary to prove that the dealer knew the defect, and that the purchaser was imposed upon by his false representation; and that, too, in a case in which a person of ordinary circumspection might have been similarly deceived. If the defect was evident to every eye, the purchaser has no remedy. He should have taken more care. If, however, a warranty was given, it extends to all unsoundness, palpable or concealed. Although a person should ignorantly or carelessly buy a blind horse, warranted sound, he may return it. The warranty is his guard, and prevents him from so closely examining the horse as he otherwise would have done; but if he buys a blind horse, thinking him to be sound, and without a warranty, he has no remedy. The law supposes every one to exercise common circumspection and common sense.

A man should have a more perfect knowledge of horses than falls to the lot of most, and a perfect knowledge of the vendor too, who ventures to purchase one without a warranty.

If a person buys a horse warranted sound, and discovering no defect in him, and relying on the warranty, resells him, and the unsoundness is discovered by the second purchaser, and the horse returned to the first purchaser, or an action commenced against him, he has his claim on the first seller, and may demand of him not only the price of the animal, or the difference in value, but every expense that may have been incurred.

Real exchanges, whether of one horse for another, or a sum of money being paid in addition by one of the parties, stand on the same ground as simple sales. If there is a warranty on either side, and that is broken, the exchange is vitiated; and if there be no warranty, deceit must be proved.

The trial of horses on sale is a very intricate one; and often leads to doubts and disputes. It is well known that a horse from a dealer's stable is seldom or ever fit for hard work until he has undergone some preparation and training. It is right that the purchaser should have a trial of him, but he should try him in a fair way; that is, in a way consistent with the state in which the animal is. If a horse from a dealer's stable is galloped far and fast, it is probable that he will soon show distress; and if he is pushed farther, inflammation and death may ensue. The dealer rarely gets compensated for this; and if it should occur soon after the sale, the animal is returned, if alive, or an action is brought for its price. When accidents have arisen in the fair trial of a horse, the decisions of the courts of law have been strangely contradictory; and, indeed, it is often difficult to determine whether the fault rests with the horse or the rider. If the horse is retained after the specified time of trial, he is supposed to be sold, with all his faults.
In London, and in most great towns, there are repositories for the periodical sale of horses by auction. They are of great convenience to the seller, who can, at once, get rid of an animal with which he wishes to part, without waiting month after month before he obtains a purchaser, and is thus relieved from the nuisance or fear of having the horse returned on account of breach of the warranty, because in these places only two days are allowed for the trial; and, if he is not returned within that period, he cannot be afterwards returned. They are also convenient to the purchaser, who can thus in a large town soon find a horse that will suit him, and which, from this restriction as to returning the animal, he will obtain twenty or thirty per cent. below the prices of the dealer. Although an auction may seem to offer a fair and open competition, there is no place at which it is more necessary for a person not much acquainted with horses, to take with him an experienced friend, and, when there, to depend on his own judgment or that of his friend, heedless of the observations or manoeuvres of bystanders, the exaggerated commendations bestowed upon some horses, and the thousand faults found with others. There are always numerous groups of low dealers, copers, and chanters, whose business it is to delude and deceive.

In speaking of the convenience and usefulness of the London horse repositories, Mr. John Lawrence says:—

"It was perhaps about the year 1740, or somewhat later, that Beavor, supposed to have first introduced the plan of sale in this mode, opened the horse repository in Little Saint Martin's Lane, London. He was succeeded by Aldridge, father of Mr. Aldridge, who retired, parting with the concern to Mr. Morris. Tattersall's repository at Hyde Park Corner, was opened about the year 1760, by Mr. Tattersall, who had previously resided at Worcester, and was proprietor of the stallion, Young Traveller. He was also engaged awhile in London, with Beavor. After the then Duke of Cumberland's decease, his stud was sold at Tattersall's in 1765. Old Tat, as he was, in due time, familiarly called, was so fortunate at his very outset, as to obtain the countenance and patronage of persons of the highest distinction, who took an interest in horses; and that important advantage continued undiminished to his successors. I first knew old Mr. Tattersall, in 1773. He was a shrewd, assiduous, and observant man, precisely one of those qualified by nature to be faber fortunæ, the maker of his own fortune; and he achieved it, becoming the founder of an opulent and respectable house."

We shall now endeavour to put the unwary on their guard against the nefarious and cheating practices of what are called Horse-chanters. There is scarcely a provincial newspaper published in which some of these individuals do not figure, either as advertisers, or before the magistrates in some equivocal transaction. The horse seems a conductor to all sorts of villainy. He is himself the object of great cruelties, and is surrounded by the most heartless of mankind. There is no article of commerce carried on in which a man has more right to have his suspicions excited than in horse-dealing. If a man goes to a repository, it would almost be the next thing to a miracle if there was not a chunter to oppose him. He runs up the price to the mark, gives the horse a good character, and expresses his high admiration of his great qualities. The same was wont to be done to a large extent in Smithfield, as well as in places of private bargain, where the chunter would approach, and make an open, though fallacious offer, bidding very near the price asked.

There is another swindling method practised among farmers' servants, or countrymen who are not likely to know much about country notes. They are what are called liberal purchasers, and pay what is asked; but pay in worthless money. In this case the countryman is so pleased with the liberality of his customer, that he is disarmed of all suspicion; and like the stranger in London, he is deprived of his horse as the other is of his money by such kind, friendly fellows, that do not know what to do with him or for him, until they despoil him of all the cash he has got.

Some time ago, an instance of doing a countryman occurred in Somersetshire. A farmer sent his man to Stafforddale Fair, to sell a horse, which he speedily did for £24, being the price he asked. Related with his success, he returned in great good humour with himself, and laid the money on the table before
his master. The farmer was equally pleased; but on a little closer examination, he found that poor John had been duped by sharpers. The notes paid him were a ten-pound note and a five-guinea note—of banks which had stopped payment—and a one-pound Dorsetshire note, altered into ten. John attempted to trace the swindlers, but without success. The same gang passed a ten-pound note of a bank that had stopped nearly fifty years before.

There seems some fatality connected with horse-flesh, that immediately leads to roguery. We never heard of any directions given for the purchase of a horse, but that among the first cautions was, "never buy one of a friend." Such seems the overwhelming contamination of this traffic, that friendship itself is no security against rascality; and the moment a man has one to sell, some degree of suspicion seems to attach itself to him. The horse-dealer seems almost, by common consent, to be placed out of the pale of respectability; and if his conduct were in a parallel with his character, he would be a most accomplished deceiver.

A dealer in a large way has generally a stock of horses on hand, from which it may be easy to select. If not, his general resources are such, that he can very quickly supply any person with what he wants. To the uninitiated in buying horses, a respectable dealer is the most eligible party to transact business with.

When we reflect on the catalogue of diseases, imperfections, and vices to which a horse may be liable, and which is left to the tyro to discover, the risk he runs in making a purchase is immense. Although he may give a good price for a horse, even more than its value, still he runs less risk in buying from a respectable dealer than from strangers. If he may have paid a top price, he is unlikely to be so cheated as he might be by the chaunting tribe. The dealer has a residence; and if there be anything to complain of, he knows where to find him. It is natural to suppose that a dealer has an opportunity of selling a horse at a better price than most other individuals; and if he has his trade, it is but reasonable that he should have his profit. Therefore, in recommending a tyro to commence his buying from a dealer, we do so on account of believing it to be the least hazardous of any other; for we will not indulge the aspirant after knowledge of the horse in the hope that he may gain it without suffering some pecuniary损失, as well as disappointment.

After he has gained some experience, it will be quite time enough for him to enter the bazaars and repositories, to trade on his own judgment; and if he has a taste for the pursuit, he will not rest satisfied till he has matured that judgment to such an extent as to find pleasure as well as profit in exercising it.

Dealers never like to take a horse back; and when this is done, the purchaser must expect to make some considerable sacrifice. No man likes to return money for any article that he may have sold in his shop; but to a dealer in horses, it is particularly objectionable. Persons who discover a horse returned, may naturally enough suppose that it was from some fault; and although the fact might be from some sheer caprice, still his value would be decreased in the opinion of those who knew it; and before he can be sold for his former value, he must wait till a stranger comes, who may know nothing of his being a returned horse. Persons conversant with buying and selling horses never think of returning them, unless from unsoundness; but the unskilled, or those who are not in the habit of disposing of horses, may naturally apply to the party to take them back again, and think him, perhaps, an unfair dealer if he refuses, on their allowing him a few guineas to boot. The fact is, a quick return is the very soul of horse-dealing; for without it, the expense soon eats the profits up. A fresh horse is more likely to meet with a purchaser than such as have lain longer in the stables. Hence the dealer's repugnance to returned horses.

In looking out for a horse in a dealer's stables, the attention of some attendant is soon attracted, when he will endeavour to put the horses into a fidgety state by his presence, in all probability with a whip in his hand. But this should, at once, be checked. The object is to see the animal in a state of repose, and as far as any exciting causes as possible. It may be difficult to take a quiet survey; for the attendant is not always obedient, but will often persevere in exciting what is wished to be seen in a quiescent state; and sometimes parties desirous of purchasing are compelled to leave the stables in disgust.
If, however, an animal likely to suit the purpose for which he is wanted is seen, return the next day, and take an opportunity of seeing him in the stable. A horse in the stall is, so far as it goes, one of the most satisfactory situations in which he can be examined. By watching the motions of his legs and feet, lameness may be easily detected should it exist; and so may his quietness in the stable be tested. Much knowledge of his disposition may be traced in his countenance, which, to the horse, as well as to the man, forms a general index to his disposition. There is not a surer index.

We will now suppose that a suitable horse has been seen, and that his price has been ascertained, when the ceremony of examining for purchase will commence. On being assured that he is quiet to approach, you will give some gentle warning with your voice, and go up to him on his near (left) side, and laying your hand on his forehand (to regard his height), you will proceed thence to examine his eyes, mouth, and countenance; still holding his head, and turning your own to the right-about, you have a view of the curve of his neck, the height of his forehand, the position of his shoulder, and the substance of his forearm. Returning to his forehand, you descend to his legs and feet, minutely examining with your fingers every part, from above, below, withinside, and without, not forgetting the knees, as the value of the animal depends much on their perfect state.

Having satisfied yourself respecting his fore parts, your eye will glance over his back, girthings-place, careess, and loins; thence proceeding to his hind quarter, and the setting on of his tail. You will judge how far he agrees in each and every respect with those rules of proportion already laid down in this work. The hinder legs and feet will demand a share of attention equally minute as the fore ones; nor should the inside or hollow of the hock be passed by without careful examination, since it often happens, that the injuries of hard labour are most apparent in those parts. A survey of the other side will complete the stable examination. Some prefer examining the eyes in the stable. To do this, place the horse in such a position as will let the light fall only in one direction, and see that they are of the same size, and equally full; that the haws are not prominent, and that one does not project more than the other; that the eyes are perfectly clear and transparent, and that their pupils are exactly alike in size as well as in colour.

Mr. John Lawrence, in speaking of the too common practice of dealers using the whip, gives the following caution, as well as expresses his honest indignation at its practice.

"Suffer no person belonging to the seller to be with you in the stall—unless you know and are well satisfied with the dealer's character—during your inspection, that the horse may not be rendered unquiet, either designedly, or at the mere presence of an habitual tormentor. A short time since, I had occasion to examine an animal for a friend at the stable of a considerable dealer. He was a very beautiful and well-shaped nag, but, as is commonly the hard fate of such, he appeared to have done too much work. The attendant, from a superabundant share of regard to my safety, must needs hold his head whilst I examined his legs, still assuring me he was perfectly quiet. Nevertheless, every time I attempted to feel below his knees, the horse started, and flew about the stall in a strange manner, to the no small risk of my toes and shins. Whilst I stood musing and wondering what could possibly ail the animal, I discovered a short whip under the arm of the jockey, with which he had, no doubt, tickled the neck and chest of the horse, whenever I stopped down with the intent of handling his legs. I wished this adept good morning.

"A fair quiet stable survey is a material prelude, the horse being under none of that excitement which will probably take place in him when abroad upon the show; unless, indeed, he should have been previously subject to that most barbarous stable discipline which I, too often, witnessed in days of yore; but which, I hope, does not exist at the present time—at least, not in so great a degree, or so usually disgrace the conduct of our dealers. I refer to the daily, probably hourly, attendance of a fellow with a whip, who flogs and cuts the horses up and down in their stalls, causing them to jump and fly about as if mad; keeping them in such a constant state of apprehension, that they dread the approach of any human
being. The motive of this was to render them active, ready, and lively on a show, and to hide defects; and, as an exaggeration of this monstrous barbarity, the unfortunate cripples had even an additional share of this discipline, being whipped and beaten most cruelly for putting out, in order to case, a crippled limb. This was a constant practice at the repositories, with the poor worn-out machines and post hacks; and I have related, in my own treatise, the case of a beautiful mare—so totally worn out, that every step she took was obviously attended with acute torture—whipped, and cut, and beaten, and checked with the curb, with all the force that a powerful ruffian could exert, whilst the tears were dropping from her sightless eyes."

To return. The horse being led out, will most probably be placed upon rising ground, for the purpose of showing his forequarters to advantage, which, also, affords the buyer an opportunity of another examination in a good light. Now is the time for regarding whether he be sound or not; for though the dealer may declare that he is as sound as a bell, still we should disregard what he may say on that subject, and judge for ourselves.

Having spoken of the eyes, we must now regard his wind. If good, on being nipped in the gullet, he will utter a noise that cannot fail to strike the ear as the emission of a sound pair of lungs; but if these are diseased, he will give vent to a dry, husky, short cough. We have, however, seen a strong man sometimes pinch the gullet of a horse with all his might, without being able to make him cough. There is another way of detecting a broken-winded animal, and that is by directing attention to his flanks; which, under such circumstances, will work either much quicker than ordinarily, or heave deeply, and with great irregularity.

Besides these, there are two other defects, which, though not anything like so distressing to the animal itself, are disagreeable to hear. Those horses affected with them go under the denomination of "whistlers," and "roarers."

The first may be known by the peculiar wheezing he is addicted to, when put to sudden or long-continued exertion; and the other by his making a roaring noise under similar circumstances. Either will display itself by the purchaser giving him a smart cut with his whip.

After making certain that there is no enlargement of the glands, that the nostrils are free from any festid smell, and that that most terrible of all diseases, the glanders, may not be apprehended, pass the hand down his legs, and if any unnatural protuberance or puffiness is found, or if, in feeling first one leg and then the other, any difference between them is discovered, disease, more or less, is present. The animal may not be lame, but he is not clean upon his legs. Splints, windgalls, and ringbones, may be present without occasioning lameness; but they are all unnatural, are considered blemishes, and are all to be regarded with a suspicious eye, as either denoting past hard work, or betokening future evils. On the same principle, a horse may have a spavin, and be only still from it at starting; or he may have a curb, or a thorough-pin, and be perfectly sound; but these are still blemishes, and, as such, detract from his intrinsic value.

The horse is next trotted in hand, or ridden; during which, the first look-out will be to discover whether he bends his knees sufficiently, and goes clear of both hind and fore legs; whether he goes wide enough behind, and whether his feet stand straight. His reining may then be observed, to see in what state he carries his head, whether he appears light in hand, or otherwise. Should he thrust out his head, he will go heavy in hand. The mode in which he is shod should also be well observed.

A second-hand horse, or one which has been a considerable time in work, may be warranted sound; but care should be used to observe whether he knuckles with bent knees, or has any other impending cause of unsoundness. Animals which appear stale and dingy in their coats, with perhaps a mixture of grey hairs; and one low in flesh, and dull, with his coat dead, may be suspected of rottenness. There may be no objection to buying a horse merely because he is low in condition. The appearance of such an animal will be readily perceived; and a horse merely suffering from not having had a kind and generous master, ought not to prove an impediment to his again having one. Indeed, we have often felt great pleasure in restoring a horse which has suffered from neglect, to good condition. Many a good one has been restored, even after he had been sent to the knackers.
A naturally vicious horse will show his disposition in the designating glance of his eyes, and by laying back his ears. It is true, the kind and playful horse will lay down his ears; but he will not be a very skilful physiognomist who cannot easily discriminate between the countenance of a vicious and a playful one. The wicked and resolute expression of the one is generally so determinedly indexed, that there are but few men who will not instantly discover it. It is hardly necessary to caution our readers against the purchase of such an animal.

These various examinations of the intended purchase may probably give satisfaction, as far as the eye is concerned; yet there may be solid objections to be adduced against their being made final. The horse has now been shown to every advantage by the seller. He has been ridden by a jockey, accustomed, by his profession, to make the most of any animal he has to show; by one whose able hands and habitual use of the spurs, do not fail to command the most implicit obedience from the animal, and which will make him put his best foot forward. A buyer, expecting to find the accomplishment of all this under his own management of the horse, may find himself very unpleasantly deceived. Many horses are occasionally restive when mounted by a timid rider, and have cunning enough, very soon, to ascertain that fact; while, with a good and fearless rider, they will go quietly.

We should always recommend, before the buyer pays his money, that he should claim the privilege of riding the animal several miles on the high road, in his walk, trot, canter, and gallop, and then judge for himself whether he is likely to suit him in his paces or not. It should be remarked, that the wind and condition of horses made up for sale, must not be put to immediate and too severe tests; and if wanted for hard work, should have sufficient preparation by moderate daily exercise, and purging, if necessary.

We have purposely refrained from alluding to the teeth till now, these being incontestably the parts of the body capable of furnishing the most certain indications of the number of years that the animal has lived; and the incisors, or nippers, in particular, are here our best informants. They are, indeed, the only teeth that give correct ideas of the age of the horse throughout almost the entire duration of his life. The difficulty of examining the molars or grinders, and the irregularity of their table, prevent our being able to obtain any result from their inspection. The period of the protrusion of the tushes varies much; and they do not rub against each other, but sideways and across, and can only be considered as an accessory means of judging.

Besides, the mare is not always provided with them.

Professor Owen, in his treatise on The Principal Forms of the Skeleton and the Teeth, says, that teeth, like bone, are the result of the combination of certain earthy salts with a pre-existing cellular basis of animal matter. "The salts are nearly the same as those in bone, but enter in a larger proportion into the composition of the tooth, and render it a harder body. So composed, teeth are peculiar to the back-boned—vertebrate—animals, and are attached to parts of the mouth, commonly to the jaws. They present many varieties as to number, size, form, structure, position, and mode of attachment; but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food. In some species they are modified to serve as formidable weapons of offence and defence; in others, as ends in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and speech.

"Teeth are always related to the food and habits of the animal, and are therefore highly interesting to the physiologist. They form, for the same reason, important guides to the naturalist in the classification of animals; and their value, as zoological characters, is enhanced by the facility with which, from their position, they can be examined in living or recent animals; whilst the durability of their tissues renders them not less available to the paleontologist in the determination of the nature and affinities of extinct species, of whose organisation they are often the sole remains discoverable in the deposits of former periods of the earth's history.

"The substance of teeth is not so uniform
as in bone, but consists commonly of two or more tissues, characterised by the proportions of their earthy and animal constituents, and by the size, form, and direction of the cavities in the animal basis, which contain the earth, the fluid, or the vascular pulp.

"The tissue which forms the body of the tooth is called "dentive.""

"The tissue which forms the outer crust of the tooth is called "cement.""

"The third tissue, when present, is situated between the dentive and cement, and is called "enamel.""

The teeth called compound, or complex, in mammalia, differ, as regards their composition, only by the different proportion and disposition of constituent tissues. The accompanying cut is the longitudinal section of the incisor of a horse; $d$ is the dentive, $e$ the enamel, and $c$ the cement, a layer of which is reflected into the deep central depression of the crown; $c$ indicates the coloured mass of tartar and particles of food which fill up the cavity, forming the "mark" of the horse-dealer.

In pursuing this interesting subject still further, we find that the variety in the pattern of the folds of enamel that penetrate the substance of the tooth, and add to its triturating power, is almost endless; but it would seem that the folds have an invariable tendency to a transverse direction across the crown of the tooth in the rodents. This direction relates to the shape of the joint of the lower jaw, which almost restricts it to horizontal movements to and fro, during the act of mastication. In the true hoofed herbivorous animals, in which the joint of the lower jaw allows a free rotatory movement, the folds of enamel take other forms and directions, with modifications, constant in each genus, and characteristic of such. In another part of his work, Professor Owen selects the horse as an example of such herbivorous dentition.

The grinding teeth of this animal are six in number, on each side of both upper and lower jaws, with thick, square crowns of great length, and deeply implanted in the sockets; those of the upper jaw being slightly curved. When the summit, or exposed ends, of these teeth begin to be worn down by mastication, the interblended enamel, dentine, and cement, show the pattern figured in the accompanying engravings. It is penetrated within by a valley, entering obliquely from behind forwards, and dividing into, or crossed by, the two crescentic valleys, which soon become insulated. There is a large lobe at the end of the valley. The outer surface of the crown is impressed by two deep longitudinal channels. In the lower jaw the teeth are narrower, transversely, than in the upper jaw, and are divided externally into two convex lobes, by a median longitudinal fissure; internally they present three principal, unequal convex ridges, and an anterior and posterior narrower ridge. All the valleys, fissures, and folds, in both upper and lower grinders, are lined with enamel, which also coats the whole exterior surface of the crown. Of the series of six teeth in each jaw, the first three, $p$ 2, 3, 4, are premolars; the rest, $m$ 1, 2, 3, are true molars, used for the purpose of grinding the food."

The accompanying plates show the appearance of the teeth at different ages, and indicate the age of an animal by their form and marks.
Fig. 1 shows the end of a jaw which marks four years and a-half old. The horse-dividers newly shot out, are still quite fresh, and not as yet on a level with the incisors or nippers. The inner edge of the latter are still untouched, and lower than the external edge. The sucking corner teeth are much more worn, and present only the extremity of the funnel.

Fig. 2 shows a horse just closing up to five years old. The corner teeth have appeared a short time, and are quite fresh and untouched. The nippers begin to lose the mark; the external edge of the dividers has undergone some wear; but the inner edge is nicked, and as yet untouched, and lower than the outer.

Fig. 3 represents the age of a six-year-old. The nippers have lost their mark; the dividers have nearly lost theirs; but the inner edge of the corner teeth is still untouched, and also slightly nicked.

Fig. 4 exhibits a jaw, in which the incisors, or nippers, mark seven years old complete; and both the nippers and dividers have entirely lost the mark; the inner edge of the corner teeth is on a level with the outer, in consequence of the tear and wear they have undergone.

Fig. 5 shows an eight-year-old: all the teeth have lost the mark, and the nippers have begun to assume the oval form. The remainder of the funnel is close to the inner edge of the table of the tooth.

Fig. 6.—This engraving is taken from the teeth of a horse that was eight years old off. All the incisors have lost the mark, and the septum of the root appears on the table of the nippers in the shape of a small transverse zone, situated in front of the funnel, and quite close to the outer edge of the tooth.

Fig. 7 exhibits the mouth at nine years old. The incisors or nippers are rounded, and the dividers have likewise begun to assume a rounded form. The remainder of the funnel of these four teeth is round, and quite close to the inner edge of the tooth. These teeth also show the septum of the root, which is most prominent in the nippers.

Fig. 8 exhibits the mouth of a ten-year-old. Here we see merely the rudiment of the funnel in the nippers, as well as in the dividers; whilst the remainder of the central enamel touches the inner edge of the table of the tooth. The nippers and the dividers are rounded, and the corner teeth present an oval form.

Fig. 9.—From the appearance of the teeth, as here represented, the horse has attained his eleventh year. All the incisors are rounded, and now carry only a slight trace of the central enamel, which touches the inner edge of the table of the tooth. The septum of the root appears in all the teeth, and the remainder of the funnel is smaller in the nippers than in the dividers and corner teeth.

Fig. 10 shows the mouth of a twelve-year-old, the nippers having lost the central enamel, and the septum of the root being rounded.

Fig. 11.—This engraving is taken from the mouth of a horse thirteen years old. The nippers have become triangular; the dividers are also assuming that form, and the corners are still rounded. The septum of the root is rounded in the four latter, and is seen in the middle of the table. The tushes are very much worn.

Fig. 12.—The horse to which this mouth belonged, might have been thirteen or fourteen years of age. The nippers are triangular, and the dividers are becoming so. The tushes are still more worn than in the preceding figure.

We will now briefly recapitulate the most important points to be attended to, in this chapter, in the purchase of a horse. However, it must be borne in memory, that

"Whoe'er expects a perfect horse to see,

Expects what never was, or is, or e'er shall be."

It is well known that there is a general idea in the minds of many, that a horse begins to decay after he has attained his eighth year. Than this nothing can be more absurd. Mr. Blaine remarks, that "a very considerable attention to the subject, over a wide field of observation, has impressed the writer with the propriety of drawing the following comparison between the ages of horses and men; that is, at these several periods of comparison, the constitutions of horses and of men may be considered as in an equal degree of perfection and capability for exertion, or of debility and decay; according as youth or age preponderates. Thus the first five years of a horse may be considered as equivalent to the first twenty years of a man; or thus—a horse of five years may be comparatively considered as old as a
AGE of the HORSE.

man of twenty; a horse of ten years, as a man of forty; a horse of fifteen, as a man of fifty; a horse of twenty, as a man of sixty; of twenty-five, as a man of seventy; of thirty, as a man of eighty; and of thirty-five, as a man of ninety. So far from this comparison being too much in favour of the horse, we are disposed to think it too little so. Horses of thirty-five years of age are as common as men of ninety, provided it be taken into the account that there are, at least, fifty human subjects to every horse; and unquestionably, a horse of forty-five is less rare than a man of one hundred and ten."

In enumerating the qualities to be attended to in the purchase of a horse, Professor Stewart gives the following summary:—

The Head.—For the eyes; for cataract, glass eyes, and specks. The nostrils; for glanders, tumours, and cold. The glands between the branches of the lower jaw; for enlargement. The throat; for mark of crib-biting strap, and the tenderness which accompanies cold. The teeth; for the age and marks of crib-biting. The veins of the neck; to see that both are entire.

The Fore Leg and Shoulder.—The seat of the collar; for tumours. The point of the elbow; for tumours. The knee; for blemishes and stiffness of that joint. The shank; for speed-cut, splint, and strain. The fetlock-joint; for enlargement, mud-galls, neurotomy, string-halt, and marks of cutting. The pastern; for ringbone.

The Foot.—For side-bones; sand-crack, contraction, thrust, corns, and flat-soles. The shoe; for signs of cutting.

The Trunk Quarters.—Each side of the chest; for marks of blisters and rowels. The space between the fore legs; for the same. The stifle; for enlargement. The groin; for rupture.

The Hock.—For capped-hock; thorough-pin, bone-spavin, and bog-spavin—not blood-spavin. Then the horse should be mounted and ridden a few hundred yards at a gallop, in order to quicken his breathing, and thereby display the presence or absence of roaring, thick wind, or broken wind.

As to the prices to be given for certain horses, Lord William Lennox says, that a hunter of the best description, if in a dealer's possession, should be about £150, the odd £50 to be more or less as the horse appears to be worth it. A strong and likely hack, £40 to £60. No more should be given for this sort of animal, as good ones can always be got at that price. A horse for general work—that is, either for the field or in harness, £60 to £80, a little more or a little less, in accordance with the apparent qualities of the animal. From these prices, he says, "you must resolve not to deviate easily."

CHAPTER IX.

SKELETON OF THE HORSE; HIS ZOOLOGICAL CLASSIFICATION.

In his Introduction to his great work on Natural History, Buffon remarks, that it is only by comparing that we can judge; and our knowledge turns entirely on the relations that things bear to those which resemble them, and to those which differ from them; so if there were no animals, the nature of man would be far more incomprehensible than it is. The truth of this is made at every step we take in the science of comparative anatomy, which, from time to time, has revealed the most unanticipated wonders relative to the most extraordinary resemblances in the structure of animals perfectly distinct. For example: who would, beforehand, expect that the same bones would be found in the horse as in the seal? Yet a comparison of their skeletons demonstrates this to be the case to a very great degree. Of all animals, the rhinoceros, rather than the camel or the dromedary, has the nearest affinity to the horse;
although a different modification of the entire skeleton may be traced in the animals with toes in even number, as compared with the horse and other odd-toed hoofed quadrupeds.

The vertebral formula of the horse is—7 cervical, C; 19 dorsal, D; 5 lumbar, L; 5 sacral, S; and 17 caudal. Eight pairs of ribs directly join the sternum, 60, which consists of seven bones and an ensiform cartilage. The neural arches of the last five cervical vertebrae expand above into flattened, subquadrature, horizontal plates of bone, with a rough tubercle in place of a spine; the zygapophyses, z, are unusually large. The perforated transverse process sends a pleurapophysis, pt, downwards and forwards, and a diapophysis, d, backwards and outwards, in the third to the sixth cervicals inclusive; in the seventh the diapophysial part alone is developed, and is imperforate. The spinous processes suddenly and considerably increase in length in the first three dorsals, and attain their greatest length in the fifth and sixth, after which they gradually shorten to the thirteenth, and continue of the same length to the last lumbar. The lumbar diapophyses are long, broad, and in close juxtaposition; the last presents an articular concavity, adapted to a corresponding convexity on the fore part of the diapophysis of the first sacral. The scapula, 51, is long and narrow; and, according to its length and obliquity of position, the muscles attached to it, which act upon the humerus, operate with more vigour; and to this bone the attention of the buyer should be directed, as indicative of one of the good points of a horse. The carocoid is reduced to a mere confluent knob. The spine of the scapula, 51, has no acromion. The humerus, 53, is remarkable for the size and strength of the proximal tuberosities, in which the scapular muscles are implanted. The joint between it and the scapula is not fettered by any bony bar connecting the blade-bone with the breast-bone; in other words, there is no clavicle. The ulna, represented by its olecranal extremitv, 54, is confluent with the radius, 55. The os magnum, in the second series of carpal bones, 56, is remarkable for its great breadth, corresponding to the enormous development of the metacarpal bone of the middle toe, which forms the chief part of the foot. Splint-shaped rudiments of the metacarpals, answering to the second, ii, and fourth, iv, of the pentadactyle foot, are articulated respectively to the trapezoides and the reduced homologue of the unciforme. The mid-digit, iii, consists of the metacarpal, called "cannon-bone," and of the three phalanges, which have likewise received special names in veterinary anatomy, for the same reason as other bones have received them in human anatomy. "Phalanges" is the general term of these bones, as being indicative of the class to which they belong; and "hæmapophyses” is the general term of parts of the inferior arches of the head-segments; and just as from the modifications of these hæmapophyses, they have come to be called "maxilla," "mandibula," "ceratohyal,” &c.; so the phalanges of the horse's foot are called—the first, "great pastern bone;” the second, "small pastern bone;” and the third, which supports the hoof, the "coffin-bone;” a sesamoid ossicle between this and the second, is called the "coronary." The ilium, 52, is long, oblique, and narrow, like its homotype, the scapula;
the ischium, 63, is unusually produced backwards. The extreme points of these two bones show the extent to which the bending muscles and extending muscles of the leg are attached; and, according to the distance of these points from the thigh-bone, the angle, at which they are therein inserted, becomes more favourable for their force. The longer, therefore, and the more horizontal the pelvis, the better the hind-quarter of the horse; and its qualities for swiftness and maintenance of speed, depend much on the "good point" due to the development of this part of the skeleton. The femur, 65, is characterised by a third trochanter springing from the outer part of the shaft, before the great trochanter. There is a splint-shaped rudiment of the proximal end of the fibula, 67, but not any rudiment of the distal end. The tibia, 66, is the chief bone of the leg. The heel-bone, "calcaneum," is much produced, and forms what is called the "hock." The astragalus is characterised by the depth and obliquity of the superior trochlea, and by the extensive and undivided anterior surface, which is almost entirely appropriated by the navicular. The external cuneiforme is the largest of the second series of tarsals, being in proportion to the metatarsal of the large middle digit, iii, which it mainly supports. The diminished cuboides articulates partly with this, partly with the rudiment of the metatarsal, corresponding with that of the fourth toe, iv. A similar rudiment of the metatarsal of the toe, corresponding with that of the second, ii, articulates with a cuneiforme medium—here, however, the innermost of the second series of tarsal bones.

In the zoological classification of the horse, he is placed in the division vertebrata—the class mammalia—the tribe ungulae—the order pachydermata—and the family solipida. The generic character is, front teeth, in the upper jaw, six, parallel; in the lower jaw, six, somewhat projecting; canine teeth, one on each side, in both jaws, remote from the rest; feet with undivided hoofs.

Of the solipida, there are several species, as the horse, the ass, the mule, the zebra, and the quagga.

Equus Caballus is the common horse.
Equus asinus, the ass, which has long been condemned to a state of the lowest servitude, and considered as a species of less dignity than the horse; and has acquired, in most parts of Europe, a character of contempt. In its natural state, however, it exhibits an appearance superior both in beauty and vivacity. It is a native of Asia, living, like the rest of this genus, in a gregarious manner. It is also said to be found in Africa, but very rarely in Syria and Arabia, where it was, in ancient times, extremely common. In its natural state its colour is white, or a very pale silver grey, with a tinge of straw-colour on the sides of the neck and body. Along the back runs a deep brown stripe of thickish wavy hair, to the beginning of the tail. This stripe is crossed over the shoulders, as in the tame animal, by another of similar colour; but it is said that this is peculiar to the male.

The food of the wild ass consists chiefly of saline, or bitter and laticescent plants. It is also fond of salt or brackish water. The manners of these animals very much resemble those of the wild horse. They assemble in troops, under the conduct of a leader or sentinel, and are extremely shy, vigilant, and swift.

The mule is nothing more than a hybrid animal, between this species and the horse; differing in strength, size, and beauty, according to the predominancy of its parent species. Mules are little used in this country; but in Spain and some other parts of Europe they are in much esteem, and are remarkably sure-footed.

Equus zebra, or the zebra, is a native of the hotter parts of Africa, being found from Ethiopia to the Cape of Good Hope; living in large herds, and possessing much of the manners both of the wild horse and the ass. It is both extremely swift and vigilant. It is of a wilder disposition than either of the former animals; and even such as have been taken very young, are with difficulty brought to any degree of familiarity, and have rarely been made to submit to the bridle.

Equus quagga, or the quagga, is nearly allied to the zebra, but marked with fewer and larger bands, of a brown colour, and chiefly disposed on the fore parts of the animal, while the hinder parts are spotted. The ground-colour of the quagga is of ferruginous tinge, especially on the thighs and back. It is of a more docile
nature than the zebra, and is said to have been domesticated at the Cape. It inhabits the same parts of Africa as the zebra, but is found in separate herds, never associating with that species, perhaps on account of the inherent ferocity of the latter.

CHAPTER X.

SPLINTS; BONE-SPAVIN; RINGBONE; ANCHYLOSIS.

SPLINTS.

Splints are bony excrescences, situated on the inside of the fore leg, and rarely occur on the outside, in consequence of that part in the structure of the horse being more under his direct weight. When the horse has one of his fore legs off the ground, there is more weight thrown on the inside of the leg that is on the ground; consequently, the small inside bone united to the shank bone has more work to perform than the outer one, from the superabundant weight it has to sustain; hence inflammation frequently begins in the attachment of the large to the small bone, which is of a cartilaginous substance, and, on the slightest exertion, readily assumes a disposition to form bone. But splint will frequently occur in horses that never have done a day’s work. Even when young, and racing about the fields at grass, splint will be produced; but when this happens from such a cause, it seldom produces lameness, as the coolness of the atmosphere in which they are kept acts as a sedative, and reduces the inflammation. Splints arising from travelling, exhibit much more inflammation than they do when they arise from the cause just mentioned. This is frequently caused by the warmth of the stable in which the horse has to lie; and although the disease may not have assumed a form above half the size of a pea, it will be the means of producing the most painful lameness. Another cause of splint is occasioned by the speedy-cut, which is just under the knee. This has been known to proceed so far, that valuable horses, good hackneys, have been doomed by it to slow work during the remainder of their lives. The cause of this is from its interfering with the bones of the knee, or proceeding inwards, and thereby affecting the suspensory ligament.

The remedies for splints are now more humane, and have a better effect, than those formerly in use. The practice at the Royal Veterinary College, is to divide the skin above and below the enlarged bone; then to pass a seton immediately over it, changing and dressing the seton, consisting of coarse tape, every day with a digestive ointment, composed of the following ingredients:

- Hog’s Lard . . . . . 6 oz.
- Common Turpentine . . . . 2 oz.

Another method practised at the College was to cut down on the top of the splint, and divide the periosteum, or the membranous skin-like substance immediately attached to the bone; the stretching of which, in consequence of the bony excrescence or splint, is the cause of the lameness. These remedies, however, though practised at this royal establishment, are not calculated for practice either in town or country, as both of them leave a considerable blemish, which always deteriorates the value of the horse. The following mode of treatment leaves no blemish, and is generally successful. If the case is a recent one,

- Spirit Turpentine . . . . 1 oz.
- Olive Oil . . . . . . . . . . . . . 2 oz.

Rub this well on the part, night and morning, and wind a woollen bandage moderately tight round the leg. By removing the ordinary shoe, and putting on a thick-heel one, it will greatly relieve the affected part. Should the lameness not disappear in the course of three days, then some stronger application
must be made, more especially if the splint is large.

Mercurial Ointment . . . . 1 oz.
Rub a piece of this, about the size of a hazel-nut, on the part, morning and night, as long as any remains; then apply

Blister Ointment . . . . 2 drachms.
By this method of practice splints will be got rid of without the fear of blemish or injury to the leg. If there is an obligation to have recourse to the last remedy above named, have a cradle on the neck of the horse, as he may, by biting it, be kept more safe from blemish.

During the application of the local remedies, take of—

Cape Aoes . . . . . . . . 6 drachms.
Resin, powdered, . . . . . 6 "
Common soap, to form into a mass.

Divide into three balls, and give one every second day. For food, give half bran and half corn, made moderately wet. Mr. Youatt says, that if splints are worth while to meddle with at all, their treatment is very simple; and recommends the hair to be closely shaved off round the tumour—the application of a little strong mercurial ointment rubbed in for two days, to be followed by an active blister. If the splint is of recent formation, it will generally yield to this, or to a second blister.

Professor Sewell introduced a new treatment of splints. He removed any inflammation about the part by fomentations or poultices, and then performed the following operation. He commenced by pinching up the skin immediately above the bony enlargement, with the finger and thumb of the left hand; and with the knife, or lancet, or scissors, made an orifice sufficient to introduce a probe-pointed bistoury, with the edge on the convex side. This he passed under the skin the whole length of the ossification beneath, cutting through the thickened periosteum down to the bone. This being satisfactorily completed, he drew the knife several times backwards and forwards—inserting a small tape or seton, which, if the tumour was of long standing, was kept in a few days. This operation is attended with very little pain to the animal.

BONE-SPAVIN.

This is an exostosis or bony enlargement in or about the inner part of the hock joint; but more particularly at its lower part; or, in some cases, at the upper end of the leg bone, though spavin may occur on any part of the hock. From the peculiar construction of the hock joint, the number of bones which are there, and its being the seat whence the principal propelling motion arises, it is little to be wondered at, that horses are so very liable to spavin. Young animals are especially subject to it, in consequence of farmers and breeders putting them to work at too early a period. Farmers generally commence using their young horses in the summer, to assist in drawing their hay or bringing in their corn. Now, as colts pull awkwardly at first, any sudden strain made on uneven ground, or a sudden start forwards, or from the violent exertion put on, the animal will, in all probability, strain his hock. This being a very complicated joint, any of these causes may produce considerable inflammation, lameness, and spavin; though there are a great number of horses affected with what is termed spavin, that never go lame at all, and some of them even very excellent hunters. This arises from the situation in which the bony enlargement has it seat. If it is at the upper end of the leg bone, and in such a situation as not to interfere with the small bones of the hock joint, it may grow to a very considerable substance, and but slight lameness exist. Should this be the case, the treatment of spavin may consist in the use of gentle counter-irritants, which invariably remove the lameness in a very short time. Cooling lotions or repellers, as they are exceedingly slow in their operation, and seldom ever restore the horse from lameness, are not to be recommended. In colts, however, the mildest methods should be preferred, though their effects are much slower. For a mild application, take—

Caucumaris, powdered . . . . . 4 drachms.
White Wine Vinegar . . . . . 4 oz.

Put these into a six-ounce bottle, and let the mixture stand three or four days, shaking the bottle four or five times a day. At the expiration of that time it will be fit for use.
Rub about two table spoonfuls of the lotion on the hock night and morning, shaking the bottle well each time. Should this not have the desired effect, apply a

**Strong Blister.**

- Cantharides, powdered . . . 6 drachms.
- Mercurial Ointment . . . . 4 oz.
- Hog’s Lard . . . . . . . 2 ounces.

Clip the hair off close, say an inch and a-half further round than the spavin extends. Rub the blister well in with the hand. In all probability this blister will remove the spavin entirely, or at least the pain and lameness; for, when once bony matter is formed, it is difficult to completely remove it. Be careful that the horse wears a cradle in every case of blistering.

Some spavins may require a second or third blister. In such cases repeat the above at an interval of about three weeks—not earlier—to prevent the chance of having a blemish.

With full-grown horses, as well as with old ones, this disease is with difficulty remedied. As success, however, sometimes attends even the milder methods, it should not, even at any age of the animal, deter us from trying other remedies. Bold adventurers succeed sometimes with them, where superior skill, under the direction of prudence, fails; but notwithstanding this, their more frequent ill effects, by exciting excessive pain and inflammation, and even causing death, should induce great caution in their use.

If the ointment is not effectual, recourse must be had to firing. In this operation care must be taken not to fire through the skin; for wherever this is done, a blemish will be certain to be left. Lay the following blister on lightly, but on no account let it be rubbed in, or a blemish will be the result.

**Mild Blister.**

- Cantharides, powdered . . . 2 drachms.
- Hog’s lard . . . . . . . 2 oz.

Smear this, or lay it lightly on the part fired. In the course of five weeks, should this first firing not have had the desired effect, fire again, and extend beyond the edges of the first operation, and apply the blister again. Mr. White, in his *Compendium of the Veterinary Art*, says that the only cure for this complaint is firing, and blistering immediately after.

The practice for the cure of spavins made use of at the Royal Veterinary College, is by introducing setons over the diseased part, dividing the skin above and below the spavin, about two inches; then with a blunt seton needle, introducing tapes—generally two—and dressing daily with digestive ointment, composed of the following proportions:

- Common Turpentine . . . . 3 oz.
- Hog’s Lard . . . . . . . 8 do.

These are melted together over a slow fire. The setons are suffered to remain for about a fortnight, being changed daily at each dressing. In some cases a very good effect is produced by this mode; but, like all other remedies, it is not applicable to all stages of the disease; in the early or incipient state, it may be considered a good remedy. During the operation of any of the above methods of practice, the following medicine should be administered:

- Cape Aloes . . . . . . . 2 drachms.
- Linseed meal with soft soap, formed into a moderately sized ball. Give one about every third day. Medicine that will act on the urinary organs must not be given while using so much blistering ointment.

**RINGBONE.**

This disease takes its name from its situation, which is at or about the joint of the large and small pastern bones. From the existence of great inflammation, it spreads round the coronet, capping the hoof with a bony ring.

This is produced by the ligaments having been injured by over-exertion; and it more frequently occurs in the hind than in the fore limbs. Overweighting the animal will produce it, or putting him to work before he finished, as it is termed. Any severe strain, and even blows will produce it. And, as it is not uncommon for ill-tempered grooms or carters to kick their horses about their fetlocks, the effect of such an act may be to set up inflammation, and ultimately to produce ringbone.

Horses affected with ringbone, may or may not be lame. It all depends on that degree of inflammation which would increase the greater deposit of bony matter, and occasion the disease to spread, which it frequently will do,
even so far that the coffin-bone, and the navicular, or nut-bone, partake of the disease.

"Horses with short upright joints," says the editor of The Horse, "and with small feet and high action, are oftener, as may be supposed, the subjects of this disease, which is the consequence either of concussion or sprain of the pastern joints. It is also more frequent in the hind foot than the fore; because, from the violent action of the hind legs in propelling the horse forward, the pasterns are more subject to ligamentary injury behind than before; yet the lameness is not as great there, because the disease is confined principally to the ligaments, and the bones have not been injured by concussion; while from the position of the fore limbs, there will generally be in them injury of the bones to be added to that of the ligaments. In its early stage, and when recognised only by a bony enlargement on both sides of the pastern joint, or in some few cases on one side only, the lameness is not very considerable, and it is not impossible to remove the disease by active blistering, or by the application of the cautery; but there is so much wear and tear in this part of the animal, that the inflammation and the disposition to the formation of bone rapidly spreads."

If the horse should be lame, the best plan to adopt is, to relieve the vessels as near the part as possible, by bleeding in the foot to the amount of at least two quarts. After replacing the shoe, and applying a pledge of tow, administer the following ball:—

Aloes, Cape. . . . . 6 drachms.
Ginger . . . . . . 1 do.

Form with soap.

Should this not be sufficient to purge the horse, increase the dose, as may be necessary, with a drachm or two of aloe, at the same time having the horse fed on bran mashes for at least a day previous. When the physic is set, apply the mercurial blister as prescribed in the case of sprain, and keep it open by occasionally applying hog's hair to the part for five or six days. In the course of three or four weeks, should the animal not have got rid of his lameness, recourse must be had to firing, which should be done at least half way up the large pastern bone, and down to the hoof, in what is called diaments. After this, lay some mild blister on; and, in most cases, the lameness will be altogether removed. If it should not, repeat the firing, and blister again.

ANCHYLOSIS.

The origin of this disease is an inflammation of the ligaments, connecting joints together, and occurring in the fore legs, particularly between the large and small pastern bones. It may also arise from sprain or laceration, as well as from various other causes, such as tumefaction of the ends of bones, caries, fracture, dislocation. As the horse becomes aged, stiffness in the joints is also apt to occur. Anchylosis, however, is a disease which more frequently occurs in the spine, or back-bone, than in any other part. When this is the case, the horse is termed rigged in the back, because he is most generally affected about the loins. The difficulty he shows in turning —giving to his body a kind of jerk, according as he may be turned either to the left or the right—has given rise to the term rig; and if he be trotted, he will have such a rolling gait, accompanied with such apparent weakness, that what is the matter with him is at once perceived. There are, however, many horses called chinked in the back, which may, in a measure, be restored, for slow work, by giving them as much rest as possible; as this kind of anchylosis of the back-bone does not interfere with the animal employed in slow farm labour. If the disease takes place in either the fetlock joints, pasterns, knee, hock, or stifle, the horse will be totally useless, and a cure is impossible.
CHAPTER XI.

FRACTURES.—THE HEAD; RIBS; LIMES; BLADE-BONE; ARM; ELBOW; SHANK-BONE; THIGH-BONE; PASTERNs; COFFIN-BONE, AND NAVICULAR BONE.

FRACTURES.

FRACTURES mean a division of a bone into two or more parts, or fragments. A simple fracture is when the bone only is divided, and not protruded through the skin. A compound fracture is a division of the bone, with a laceration of the integuments, the bone mostly protruding. A comminuted fracture is where the bone is splintered in more than one direction. A fracture is also termed transverse, oblique, &c., according to its direction.

The fractures that most generally occur are in the head, occasioned by horses running violently against a post or bar; the ribs, hipbone, thigh-bone, and, indeed, all bones of the leg, caused either by falls, or kicks from other horses. We will first consider

FRACTURE OF THE HEAD.

Although this is not a very common case, still, it is likely to occur. A case illustrative of the manner in which it sometimes happens, took place in India. At the usual watering-time of the horses in the afternoon—about five o'clock—one of them broke loose from the hands of the man who attended him. This occasioned a tremendous outcry among the soldiers, many of whom ran after him, and so frightened the animal, that he fled with all the reckless speed he could command. In this state he made a desperate rush into his standing in the stable, and fractured his skull against its top bar with such violence, that he was knocked down by the effects of the blow. He received a wound on the head about an inch wide. Fearing that concussion of the brain had taken place, the veterinary surgeon had the horse bled to the amount of six quarts, the head frequently fomented with warm water, and no food given to the animal that night. In the morning he appeared better. The fomentations were kept up, and six drachms of aloes given him. This treatment was continued for two days, when the process of healing the skin was commenced, and accomplished in about a week.

At the end of the third day, when about to discharge the horse as cured, it was found that he was attacked with lock-jaw. This circumstance suggested that the bone must have been fractured, and that pressure on the brain was the consequence. The horse was immediately cast, and two sections in the skin, forming two sides of a triangle, made with the scalpel. On examining the parietal bone, it was found that the skull had a perpendicular fracture of about an inch and a quarter in length, and that a piece of bone had been splintered off, about three-quarters of an inch long. The splintered bone was now extracted with a pair of sharp-pointed forceps, the skin drawn down, and half-a-dozen sutures attached. The fracture was then treated as a common wound, and dressed with digestive until granulations began to form. Under this treatment, it was completely healed in about three weeks. The lock-jaw yielded, by degrees, to copious bleedings and solution of aloes, day by day, until purgation was produced. This interesting case is represented in the accompanying PLATE of the horse’s head.

EXPLANATION OF PLATE.—“FRACTURES.”

A shows the situation of the parietal suture, running perpendicularly up the front of the head.

B, the fractured part, just on the suture.

C, the skin dissected and laid back, the upper part being held in its situation by an assistant.

FRACTURES OF THE RIBS.

Fractures of the ribs frequently occur, and are very often produced by kicks from other horses, more especially when at grass than at
FRACTURES.

1. The Boot or laced Stocking
   to be applied to a fractured leg

2. The lace to be used
   as in a common boot

A Sling or Suspender in ease of
Fractures or other accidents
any other time. They are, also, frequently the
effect of blows dealt to such animals as are
used in large towns by costermongers and
dustmen, who, if a horse cannot travel at the
rate they require, a large stick is made to re-
sound on his sides with an inhumanity only
equalled by the ignorance of the brute who is
entrusted with the use of such a weapon.
These fractures generally unite of themselves;
Nature setting up the healing process herself;
and the accident seldom or ever coming to
light until the beast finds its way to the yard
of the knacker. “The two ribs behind the
eelbow,” says Hurterel d’Arboval, “are the
most subject to fracture; and the false ribs,
from the yielding motion which they possess,
are least liable.”

FRACTURE OF THE SPINE.

Fracture of the spine may arise from lying
down in a narrow stall, in which there is diffi-
culty in rising again; or sometimes from the
horse turning over in the standing, whilst
lying down, so that there is not room for him
to get his hind legs clear of the stall-post.
Where this is the case, he struggles to regain
his feet, and the ligament of his back becomes
so much strained, that inflammation com-
mences, and in all probability terminates in
anhysnosis. It sometimes occurs in casting a
horse to perform an operation, notwithstanding
every possible care may have been taken to
prevent it.

For this fracture there is no remedy. In
the eleventh volume of the Veterinarian, Mr.
W. C. Spooner relates a case of spine-fracture
of considerable interest. A horse had been
clipped about three weeks, and was subse-
quently sharply galloped upon rough ground,
and pulled up suddenly and repeatedly, with
the object of sweating him. After this, he did
not go so well as he had done previously, nor
would he canter readily, although he had been
much used to that pace. Two days before he
was destroyed, the groom was riding him at a
slow pace, when he suddenly gave way behind,
and had to be carried home, and he could not
afterwards stand. He had, it is supposed,
slightly fractured the spine when being su-
ddenly pulled up, but without displacing the
bones. There are, doubtless, many similar
cases to this.

Attempts have been made to cure this frac-
ture by blisters and charges, but never with
any good effect.

FRACTURE OF THE LIMBS.

As in all other cases of fracture to which
the horse is liable, those of the limbs are as
difficult to cure as any. Consequently, in
many instances, the animal has to be de-
stroyed; but many fractures of the limbs may
be restored so far as still to make the horse of
considerable value. This will especially be
the case if he is a well-formed stallion, or if
she is a good mare. The breed of either may
not only be kept up, but may be useful for
many purposes. Of a case of fracture of the tibia,
Mr. J. S. Mayer gives an interesting account.
A horse had received a blow on this part of the
leg, but for two or three days little notice was
taken of it. When he, however, was called in to
examine him, he found the tibia to be obliquely
fractured, about midway between the hock
and the stifle, and a small wound existing on
the inside of the leg. The process of setting it
was as follows:—The leg, from the stifle down
to the hock, was well covered with an adhesive
compound, then wrapped round with fine tow,
upon which another layer of the same adhesive
mixture was laid, the whole being well splinted
and bandaged up, so as to render what was
a slightly compound fracture a simple one.
The local inflammation and sympathetic fever
that supervened were kept down by anti-
phlogistic measures. At the end of six weeks
the bandages and splints were removed, and
readjusted in a similar way as before; and, at
the termination of three months from the
time of the accident, he was discharges cured:
the splints being wholly taken off, and merely
an adhesive stay kept on the leg. The horse
is now at work, and quite sound, there being
merely a little thickening where the callus is
formed.

FRACTURE OF THE BLADE-BONE.

Fracture of the blade-bone is not at all un-
frequent, and particularly the neck of the
bone. This is caused either by kicks, or falls
when going at a fast trot; so that when the
horse comes to the ground, one leg is ex-
tended before him, and the other under his
body. With coach-horses, it most frequently
181
THE HORSE, AND

FRUACTURES.

takes place. The remedy is, first to draw about four quarts of blood from the plate vein, at the anterior part of the leg. The animal should be slung, so that the feet just touch the ground. This being completed, bathe well with flannel dipped in hot water. Repeat this until the inflammation appears to subside. Feed with cold bran mashes, and give the following ball:

Cape Aloes . . . . . . . 4 drachms.
Linseed Meal . . . . . . 1 do.
Form with soft soap.

If this should not be sufficient to keep the system cool, repeat it in three days.

Apply the following liniment to the shoulder:

Ol Terebinth . . . . . . 2 oz.
Ol Oliva . . . . . . . . . . 2 do.

Continue this treatment for about three weeks, then give the horse a month’s run at grass, where he will be most likely to lie quiet. By the end of this time he will probably be fit for work.

FRUACTURE OF THE ARM.

This bone is frequently fractured from its being so exposed and so very liable to kicks. When it occurs, however, there is a much greater probability of effecting a cure of it than there is in the fracture of the blade-bone. In treating for it, the horse must be slung lightly, as in the preceding case; but, instead of taking blood from the arm, let it be taken from the jugular vein of the neck. Treat in every other respect as directed for the foregoing; and take a piece of very broad tape, four yards long, and bind it round the fractured part tolerably tight. Let it remain on two days, then remove and apply more of the liniment; after which put the tape on again, and continue in this manner until the horse can put his foot to the ground. When he is able to do this, remove the sling, and let him have a loose box for a week or two before he is turned out.

Mr. Gloag, of the 10th Hussars, tells us of an entire black cart-horse, which was grazing in a field into which some mares had been accidentally turned. One of them kicked him severely a little above the knee. He, however, contrived to get home; and being carefully examined, there was found a simple fracture of the radius, about an inch and a-half above the knee. The ends of the fractured bone could be heard distinctly grating against each other, both in advancing the leg, and turning it sideways from the body. He was immediately placed in a sling not completely elevated from the ground, but in which he could occasionally relieve himself by standing. The leg was well bathed with warm water, and the ends of the bone brought as true to their position as possible. Some thin slips of green wood were then immersed in boiling water until they would readily bend to the shape of the knee; and they were tied round the joint, reaching about nine inches above, and six below the knee, the ends of them being tied round with tow.

FRUACTURE OF THE ELBOW.

This is one of those fractures which must be united in the same manner as we have seen practised in regard to the arm. There is, however, sometimes great difficulty in keeping the limb sufficiently relaxed to accomplish this; therefore, when the horse is slung, a side line should be put on, or, as a makeshift, the end of a halter fastened round the pastern, and passed up to the sling-tackle; the foot being drawn about four inches off the ground, to relax the flexor muscles. When this is done, proceed in the same manner as recommended in the preceding practice of the arm.

Mr. Youatt recommends a large quantity of tow, saturated with pitch, to be placed round the elbow, and confined with firm adhesive plasters, the ground being hollowed away in the front of the injured leg, so that no pressure shall be made by that foot.

FRUACTURE OF THE SHANK-BONE.

When a fracture of this bone takes place, it may be restored, with good management; because bandages and other compresses may be applied with greater facility, and in greater variety, after securing the horse by means of assistants. The first article to have ready is a leathern bandage something like a leathern boot, about seven inches long, with holes in it, as represented in one of the engraved sheets of this work. This must be so made, that, when it is laced, it should not touch the edges by a quarter of an inch. Being prepared with this,
place the ends of the fractured limb as evenly in contact as possible; then get an assistant to lace the boot tight on, which will act as a kind of splint, to secure the bone in its proper situation. After this, bandage the leg well from the knee to the fetlock, with four yards of a flannel bandage. Remove all straw and litter; and if much irritation appears about him, give—

Cape Aloes . . . . . . 4 drachms.
Resin . . . . . . . . . . . . 1 do.
Soft soap to form the ball.

The flannel bandage must not be removed for at least a week; when a little of the liniment prescribed for the fractured blade-bone may be poured in at the top of the boot, so that it may run down between the boot and leg. Pursue this plan until the boot can safely be removed, then apply the liniment and the woollen bandage only. For food, if the animal is accustomed to the stable, give half bran and half oats made damp. If the accident occurs while the horse is at grass, give bran mashes only.

In the representative plate, A shows the form in which the boot is to be made; B, the length from top to bottom, about seven inches; C, the lace to draw the edges together within a quarter of an inch, in order to give it the requisite tightness.

FRACTURE OF THE THIGH-BONE.

The thigh-bone is sometimes fractured at its lower head, where it joins the bones of the hock, though this is by no means a common case. There is no doubt, however, that many horses are killed from the appearance of the fracture; the leg, below where it has occurred, dangles and shakes about, as if only sustained by the common integument—or skin—so that the horse literally goes on three legs. It arises sometimes in consequence of the temper of the horse, or it may occur from a sudden slip of the hind leg on wet slippery stones, in going up hill.

A horse had got his leg entangled between the foot-board and the bar, and so near to the middle that he could not extricate it. He consequently made a sudden plunge, and snapped his thigh just above the head of the lower end of the thigh-bone. He was put into a friend's stable, hard-by where the accident happened, and the veterinary surgeon was immediately sent for. The leg was dangling as if by a piece of cord, and the horse was restless, and sweating profusely from the pain he was suffering. The treatment was as follows:

The surgeon first got an old horse-collar, which he put on the horse; then a roller, to which was fastened the top of the collar, with a strap to prevent its getting forward on to his neck. The bow part of a halter was then put round the fetlock joint of the fractured leg, passing the other end between the fore legs of the horse, and into the collar, the end of which was given to an assistant to hold until the horse's leg was got into a proper situation. A good woollen bandage was next procured; and the gentleman to whose house the horse had been taken, fortunately happened to have by him three parts of a bottle of liniment, composed of oil turpentine and oil olive. Two table-spoonfuls of this liniment was gently rubbed on the part; then the man who held the halter was desired to draw the leg gently forward, until the parts were brought as even together as possible. This being satisfactorily accomplished, an assistant, with the bandage, bound the parts up tight and firm; after which the halter was made fast to the bottom of the collar. The bone was now replaced. The bandage was not removed for a week, when the limb was found to be doing well. The liniment was continued, and the line kept to the foot for three weeks, when the horse was able to be moved about a few yards. On account of the restlessness of the animal, no medicine could be given him, and two men sat with him day and night. His principal food was bran mashes, as a substitute. This animal being an entire horse, and a favourite, the owner would have him castrated, which operation was performed on him; and, on getting well, he turned out one of the best gig horses in the country.

Another case was that of a fine brown horse belonging to a gentleman residing in Red Lion-street, Holborn; and the accident occurred when going up Holborn Hill, during the frost of a winter day.

The horse was placed under the care of a very skilful metropolitan veterinary surgeon; but the owner of the horse, regretting the accident very much, wished he could get rid
of him at five pounds. The veterinary surgeon who treated the last case, bought him at that price, with a further stipulation that he should have stable-room, and a man to look after him for a month. Within that period the horse was removed to his owner's stable, whence he was turned out for another month. By this time he had become perfectly upright, and was sold for twenty-five pounds. During the month the horse remained with the gentleman of whom he was purchased, he underwent the same treatment as described in the other case.

FRACTURES OF THE PASTERN BONE. THE COFFIN-BONE, AND NAVICULAR BONE.

There is no remedy for these. When the fracture is in the lower pastern, and of neither a compound nor a complicated nature, it may be reduced by proper bandaging; and this has sometimes been the case. When it is in the upper pastern, it is easily discovered, and is often the result of a violent effort made by the horse to prevent himself from actually falling when he has made a stumble. In treating for it, if it runs laterally across the bone, a bandage steeped in some adhesive matter is applied from the coronet to the middle of the leg. Over this some damp or wet pasteboard should be moulded, and afterwards enveloped in a linen bandage. A small splint should next be applied, before and behind, on each side, and the hollow places filled with tow, with the view of giving them an equal bearing. Should this not be sufficient to insure security, other splints, thicker and broader, should be placed over those, extending to the knee or the hock.

In reference to the coffin-bone, Mr. Percivall says—"Buried as the coffin-bone and navicular bones are within the hoof, and out of the way of all external injury, as well as of muscular force, fracture of them cannot proceed from ordinary causes." From whatever causes these fractures are produced, however, "Let your remedies," says Mr. Mayer, "be governed by those principles of science, those dictates of humanity, and that sound discretion which, while they raise the moral and intellectual superiority of man, distinguish the master of his profession from the bungling empiric."

CHAPTER XII.

DISLOCATIONS.—THE STIFLE-BONE; SESAMOID BONES.

THE STIFLE-BONE.

Dislocation of the stifle-bone frequently happens from kicks and slips out of the hind leg, so that the bone becomes thrown out of its socket. When this happens, the limb becomes totally helpless, and the horse draws it after him in the most distressing manner.

The treatment is to extend the limb forward, and fasten it in the same manner as described for fracture of the tibia. Having done this, place one hand against the bone, and press moderately from you with the other; then take hold of the point of the hock, and you will feel the stifle-bone snap into its place or socket. A re-occurrence of this accident can only be prevented by using counter-irritants all round the joint. For these take

- Ol Terebinth . . . . . . 3 oz.
- Ol Olive . . . . . . . 3 do.

Apply three or four table-spoonfuls to the stifle, all round the joint, morning and night. This will create considerable swelling; and by so doing, keep the stifle-bone in its socket. Should this not be found sufficiently powerful to retain the bone in its place, take

- Cantharides . . . . . . 1 oz.
- Ol Terebinth . . . . . . 4 do.

Shake well together when used.

This will occasion a considerable swelling, but will have the desired effect.
THE SESAMOID BONES.

Sesamoids is the name given to those bones which are situated at the back part of the fetlock joint, and are attached, at the upper end or point, to the suspensory ligament, the flexor tendons passing in a concave groove between the two, in their passage to the pastern and coffin-bones. They take their name from their resemblance to maize, or what is perhaps better known as Indian wheat. They have a peculiar elastic movement. Every step the horse takes, and more especially in the fast trot or gallop, they partially descend, on his putting his foot to the ground. This is easiest seen in long-pasterned horses, where the fetlock—hair—almost seems to touch the ground. If the animal is over-weighted, this will be distinctly observed.

The inelastic connection which these bones have below, to the head of the large pastern bone, and the decided elastic connection they have above to the suspensory ligament, clearly show how easy they may be partially, if not altogether dislocated. This is more ready to happen on the inner side, in consequence of the superincumbent weight being thrown on that side when the other foot is in the air, or, to speak more plainly, off the ground.

The action of the sesamoids being backwards and downwards, the upper end of the elastic attachment expands; and this expansion, driven to excess, either by over-weight, heavy ground, or when the animal is at the top of his speed, brings the non-elastic attachment below into such violent action, that the bones become incapable of contending with it. The consequence of this is, that the ligamentous attachment is ruptured. This is not an uncommon case; for in racing as well as in hunting, the horse sometimes makes a sudden drop, which, in many instances, is taken for what is termed "breaking down;" but it is no such thing. It is the rupture of a portion of the lower attachment of the sesamoid bones, principally on the inner side—when this side of the fetlock joint will appear much larger than the outer. If the hand is passed down the leg, over the part, pressing gradually as it is moved down, the seat of partial dislocation will at once be discovered, not only by the projection of the upper end of the bone, but by the pain which the horse will show himself to be suffering on pressing the most prominent part of the bone.

This accident has occurred, and the inflammation run so very high, that the whole of the leg, up to the knee, has been swollen to such an extent, that the disease has been taken for strain in the back sinews, when, in fact, it entirely arose from this partial dislocation of one of the sesamoid bones.

The curative treatment of this disease always involves a considerable space of time; although the time might be very much shortened if persons discovered the part affected at once. All liniments, or blisterings, will never permanently remove it, though they may relieve it; but when the horse is brought into use again, he becomes lame. On this account recourse must at once be had to firing; not in a partial manner, but it must be extended a little above the bifurcation of the suspensory ligament—say about an inch, and as far as half-way down the large pastern bone. Fire all round the leg completely; then lay lightly on it—

- Cantharides \[4\] . . . . . 4 drachms.
- Hog's Lard \[2\] . . . . . 2 oz.

Take the necessary precaution to prevent the animal either rubbing or biting the leg. Whilst he is in the stable, give him bran mashed cold, and

- Cape Aloes \[4\] . . . . 4 drachms.
- Ginger \[1\] . . . . . 1 do.

Mix, to form a ball, with soap.

If he should be costive, which is sometimes the case, repeat the medicine before he has a run at grass, which he ought to have in about nine days after the firing. The accompanying explanatory engraving, showing a section of the foot, its bones and ligaments, with the appearance of the hoof in a healthy and diseased state, will greatly assist the reader in obtaining a knowledge of the anatomy of that important member of the horse.
CHAPTER XIII.

GREASE; MANGE; SURFEIT; MALLENDERS; SALLENDERS; WARTS; HIDE-BOUND; FARTY.

GREASE.

Formerly this disease was a pest to the stables of almost every horse-master in the kingdom; and though simple in itself, the real cause of it lay in obscurity for many years. It is not only disagreeable, but painful in the greatest degree, and not unfrequently lays the foundation of other diseases, such as cracked heels, canker, and their kindred affections. Nothing was more common than to see it in the stage and hackney-coach horses, the farmer's horse, and, indeed, every kind of horse except the racer. Grease is an inflammation and suppuration of the vessels of the skin, generally in the hind legs; the circulation being weaker there, on account of their being situated at a greater distance from the heart, when, from a want of uniformity of action with the other parts in the circulation, a congestion takes place.

The cause of this disease is the quickening of the circulation by the horse being brought into a hot stable, most likely with his hind legs wet, the evaporation of which produces cold, to be followed by congestion, as the warm stable increases the action of the heart.

It does not affect all horses alike, nor all parts alike, certain descriptions of animals being more susceptible to the disease than others. Thorough-bred horses, such as the racer, are the least subject to it, principally from the fineness of their skin, and the care which is taken of them—proper attention being paid to the temperature of their stables. If a thorough-bred horse were exposed to cold for years, his skin would become thicker and thicker; and such horses would degenerate.

There are many circumstances which predispose to grease. The first is, thick skin and white hair, which is a proof of a weak circulation. Another circumstance is the colour and make of the animal—light chestnut, with white legs, narrow chests, and long legs. "Everything," says the editor of The Horse, "that has a tendency to excite inflammation in the skin of the heel, is a cause of grease. Therefore, want of exercise is a frequent source of this disease. The fluid which accumulates about the extremities, and is unable to return, is a source of irritation by its continued pressure. When high feeding is added to irregular or deficient exercise, the disease is still more likely to be produced. Want of cleanliness in the stable is a frequent source of grease. When the heels are imbedded in filth, they are weakened by the constant moisture surrounding them—irritated by the acrimony of the dung and the urine, and little prepared to endure the cold evaporation to which they are exposed when the horse is taken out of the stable. The absurd practice of washing the feet and legs of horses when they come from their work, and either carelessly sponging them down afterwards, or leaving them to dry as they may, is however, the most common origin of grease."

This disease often breaks out in October, when the legs of the animal begin to feel the change of season, and are wet and cold. After being brought into stable, the heat causes evaporation to take place; and in proportion as horses become cold, so are they susceptible of heat, if not governed by specific limits.

Grease may be either local or constitutional. In its local form it is generally severe in proportion to the relative temperature the parts have been exposed to. Heat after cold is then an exciting cause, and according to the previous cold, it acts; the cold being in part governed by moisture, and the length of time occupied in evaporating: if, therefore, the legs of an animal with much hair, hold most water, and produce much cold, so will they be proportionably liable to grease.

From these facts, it is natural to conclude, with Mr. Youatt, that the practice of washing the legs, without they are afterwards wiped dry, is bad; for, by rubbing them quite dry, there is done to the vessels of the heels a similar act to that which the heart is doing to
the arteries; namely, increasing the circulation, and preventing congestion and inflammation. If the dirt cannot be perfectly rubbed off, it is better to leave a little of that than have a great deal of grease.

In order, then, to avoid grease, when horses are brought into the stable, let them have as much air as possible, by opening the windows, so as to make the increase of circulation gradual.

Many opinions have been advanced, to show that grease is only local; but other cases show it to be thoroughly constitutional. This is proved by the fact of many horses having it during a number of years, though the greatest pains may have been taken with them to prevent it. "There is no rule without exception;" and impurities may be lurking in the system. If this is the case, nature takes these means to get rid of them, and wisely selects those parts as remote as possible from the vital principle of action; for, it is well known, from the kind of horse, and the care constantly taken of him, if it appears at all, it must arise from diseased blood, or an hereditary taint from sire to dam.

In the treatment of grease, the first thing to be done is to bleed the horse according to size and condition, to the extent of from three to six quarts. After this, give him bran mashes only; regulate him as directed in the article on Conditioning Hunters: at night, give him one of the doses of physic, as recommended at the conclusion of the same article. Take a bucket of warm water, and some soft soap, and well wash out his heels; free them from all scurf and scabs, dirt, and any other offensive matter that may be lodged in them. This done, get for a poultice four ounces of linseed meal; pour sufficient hot water to make it of a proper consistency; then, just as about to apply the poultice, have ready a pot of digestive ointment, composed of the following:—

| Common Turpentine | 2 oz. |
| Hog's Lard | 2 do. |
| Alum, finely powdered | 3 do. |

Melt the turpentine and lard together; then sprinkle in the alum, and stir till cold. Should this not be found sufficiently strong, add

| Sulphate of Zinc | 1 oz. |

These remedies are generally found sufficient to heel the cracks and sores of the heels; but care must be taken not to stop the discharge too suddenly, and especially if of a constitutional nature.

Some constitutions will not even admit of ointment being applied. If such be the case, prepare

| Sulphate of Zinc | 8 oz. |
| Boiling Water | 2 pints. |

Apply this lotion frequently to the heels.

If a mild lotion be required, first use alum instead of the zinc, varying the dressing as it may be requisite.

At the end of five or six days, give another dose of physic, as directed before. The horse should have exercise, if the weather is dry; but on no account should his legs be suffered to get wet. A bandage round them will be found highly beneficial; and, by all means, put him in a loose box, or bay of a barn, that he may exercise himself at liberty. When the process of physicking is concluded, give diuretic balls, composed of the following ingredients:—

| Resin, powdered | 8 oz. |
| Nitre, do. | 4 do. |
| Juniper Berries | 4 do. |

Soft soap, to form the mass, and divide into twelve.

Give one of these balls every second day. By this treatment grease will be got rid of; but constantly bear in mind, to prevent it there is nothing to equal cleanliness.

**MANGE.**

This distemper is so universally known, that a general description of its most predominant features is unnecessary. Let it suffice that a mere superficial view of it
The mange itself is found in the existence of a parasite burrowing in the skin, known as the *Acarus sebaceus equo*, which bears a strict analogy to the parasite which produces the same disease in the dog, and the itch in man. It belongs to the family of mites, and is found in all kinds of preserved animal and vegetable substances. It has eight legs, and has an uncommon power of tenacity in adhering to the skin.

In treating for the mange, commence to feed, night and morning, with half bran and half malt, or with equal parts of oats and bran. It is preferable to have the malt made slightly wet, not sloppy. Sprinkle a handful of coarse brown sugar in it; then mix all together, and give morning and night. For the middle-day feed, give a quartern of sweet oats, with a handful or two of chaff. During this treatment, which must be continued for at least a week, when it will begin to soften his skin, give the best and sweetest hay that can be procured.

At the expiration of a week, when the frame becomes more invigorated, discontinue the mash, and let the diet be changed to good oats, with a handful of bran night and morning, first sprinkled with water, that one of the following powders may just adhere to it:—

**Sulphur** . . . . . . . . 1 lb.
**Prepared Antimony** . . . . . 1 do.

Rub these well together in a mortar, and divide into twenty-four equal parts. For the middle-day feed, continue the oats and chaff, dry. External applications may now be begun. For these, procure a pail of warm water, and a quarter or half a pound of soft soap, or more if required, and tie a portion of it in a linen or woollen rag. Let every infected part be thoroughly washed, and well cleansed with this, by forming a substantial lather, till no scurf or filth remains on the surface. Then rub tenderly with a linen towel until dry, and, on the following morning, begin to rub in a necessary portion of the following ointment upon every part affected, as the urgency of symptoms may require; and repeat daily until satisfied of the cure:—

**Mercurial Ointment (weak)** . . . 8 oz.
**White Hellebore, powdered** . . . . 3 do.
**Olive oil, sufficient to make it soft**.
Or, use the following, which may be a more convenient application:

White Hellebore, powdered . . . . 4 oz.

Boil this in three pints of water until reduced to one quart; then add—

Muriate of Quicksilver . . . . 2 drachms, after having been dissolved in

Muriatic Acid . . . . . 3 drachms.

This lotion is to be applied to all the affected parts with a small piece of sponge, having first poured a portion of it into a saucer. This is a very efficacious remedy, and the disease has been perfectly cured by it in three dressings. It should not be applied, however, until the horse is sufficiently strong to bear the application.

Continue the use of the powders before mentioned, with, occasionally, nitre in his water—an ounce is sufficient at one time—for three weeks or a month; and so soon as it is conceived, by his condition, that he is in a state to bear it, take away a moderate portion of blood—say between two or three quarts; give him afterwards two mild doses of physic, selected from the prescriptions on that article. This will be found greatly to renovate him.

The horse, from his previously impoverished condition, will be much restored by the following tonic medicine:

Sulphate of Iron . . . . 12 drachms.
Gentian, powdered . . . . 12 do.
Ginger, ditto . . . . 6 do.

Form into a mass with honey, divide into six balls, and give one every day. By this means his constitution will be strengthened; and that poverty-stricken look with which he had before been stricken, will gradually disappear.

With regard to the horse’s trappings or appointments, such as the saddle, bridle, clothing, or harness, either gig or cart, they should be well washed and cleansed with soft soap and hot water. The stable should be well limed and whitewashed, so that every particle of the disease may be totally eradicated. This and good keep will prevent a recurrence of the affliction. In the treatment of the mange, Mr. Youatt doubts the propriety of bleeding in some conditions of the patient. “If mange is the result of poverty, and the animal is much debilitated, bleeding will increase the evil, and will probably deprive the constitution of the power of rallying. Physic, however, is indispensable in every case. It is the first step in the progress towards a cure. A mercurial ball will be preferable to a common abietic one, as more certain and effectual in its operation, and the mercury probably having some influence in mitigating the disease. In this, however, mange, in the horse, resembles itch in the human being. Medicine alone will never effect a cure. There must be some local application. There is this additional similarity—that which is most effectual in curing the itch in the human being, must form the basis of every local application for the cure of the mange in the horse. Sulphur is indispensable for every unguent for mange. It is the sheet-anchor of the veterinary surgeon. In an early and not very acute state of mange, equal portions of sulphur, turpentine, and train oil, gently but well rubbed on the part, will be applied with advantage. Farriers are fond of the black sulphur; but that which consists of earthy matter, with the mere dregs of various substances, cannot be so effectual as the puro sublimed sulphur. A tolerably stout brush, or even a curry-comb lightly applied, should be used, in order to remove the dandruff or scurf wherever there is any appearance of mange. After that, the horse should be washed with strong soap and water as far as the disease has extended; and when he has been thoroughly dried, the ointment should be well rubbed in with the naked hand, or with a piece of flannel. More good will be done by a little of the ointment being well rubbed in, than by a great deal being merely smeared over the part. The rubbing should be daily repeated.”

SURFEIT.

Of surfeits there are two kinds, originating in different causes; one being no more than an advanced stage of hide-bound, or out of condition, which, having been long neglected, continues to increase, with all its concomitant symptoms, till the blood becomes affected, and Nature sets up this process to relieve herself through the skin.

The other kind of surfeit may be attributed to drinking cold water. This differs from the other in cause, but very little in effect; and is that kind where, from ignorance or inattention,
a horse is suffered to drink immoderately of cold water when in a violent perspiration, and the blood, consequently, in the highest degree of circulation.

The shock nature sustains by this revulsion may be easily imagined. The blood, when in its greatest velocity, is instantaneously checked by the sudden application of cold to the stomach. The stomach and skin having an intimate sympathy, the pores of the latter become, as it were, instantly plugged up, when serious parts of the blood, which extravasates itself, and, by an effort of nature, is propelled to the skin for transpiration, is obstructed, and has its passage to the surface absolutely prevented, and rendered impracticable. Thus fixed, it becomes united with the perspirable matter already confined there—forming a morbid combination—and is, in the course of time, compelled, by the progress of internal inflammation, to make its way through the skin, upon which it, at last, appears in a variety of forms, assuming distinct degrees of malignancy, according to the state, habit, and constitution of the subject at the time of attack.

In treating for this disease, first remove cutaneous obstruction, correct the acrimonious state of the blood, and gently quicken the circulation. The better to gain this object will be to take away a moderate portion of blood, about three quarts, that the impetus may be encouraged; open the body with warm bran, and according to the mildness or inveteracy of its appearance, give—as the case may require—either two or three of the following purging balls, allowing sufficient time between each dose, and exerting more than usual precaution on account of avoiding cold; for although this quantity of mercury will be remarkably gentle in operating, and may be administered with the greatest safety and effect; still great care is required in all cases where this mineral is given, whether to man or beast.

Barbadoes Aloes . . . . 6 drachms.
Calomel . . . . . . . . . . 1 do.
Ginger . . . . . . . . . . . 1 do.

Soft soap, sufficient to form the ball.

After the course of physic has been regularly gone through, let strict attention be paid to the directions set down relative to food, dressing, and water. In three days after the last dose of physic, begin with the following course of alternative powders:

Antimony, powdered . . . . . . . . 1 lb.
Salphur . . . . . . . . . . . . . . . . . . . 1 do.
Cream of Tartar . . . . . . . . . . . . . 4 oz.

These are to be well mixed together, and divided into twelve equal parts, giving one every night with a feed of corn; which, being first sprinkled with water, the powders will adhere to it, and ensure their consumption. A handful of chaff is excellent to make the powders adhere. Whilst giving the alternatives, occasionally give an ounce of nitre in the morning water.

Should any trivial eschars, scabs, or excretions prove obstinate upon any part of the body, they may be washed with a solution of zinc.

Zinc . . . . . . . . . . . . . . . . . . . 1 oz.
Boiling Water . . . . . . . . . . . . . . . 6 "

Dissolve the zinc in the boiling water, and apply to the sores, with a small piece of sponge. This must be continued until the sores are healed.

MALLENDERS.

These are cracks, situated directly on the back part of the knee-joint; occasioned, in general, more by neglect in grooming, than by any casual or constitutional defect in the subject. The matter they discharge is, in some cases, thin, and of an acrimonious nature. In others, it forms a kind of glutinous discharge, and makes an appearance of small scabs, or scurfy eschars upon the surface, constituting a want of flexibility, and frequently causing considerable lameness. The first thing to be done is, to have the parts well washed with soft soap and warm water; repeating the washing night and morning, till the eschars relax from their rigidity, and separate of themselves. This will be considerably promoted by rubbing in lightly, after each washing, a small quantity of hog’s lard, which will loosen the scabs, and cause them to fall off much easier when washed.

As soon as the cracks are perfectly free from scabs or scurf, apply the following ointment:

Strong Mercurial Ointment . . 1 oz.
Hog’s Lard . . . . . . . . . . . . . . 1 "
Gunpowder, finely powdered . 4 drachms.
Let these be well worked together, and applied morning and night. This will stimulate the parts, and make them quickly heal. The washing, morning and night, must be continued about an hour previous to applying the ointment; which will give the parts time to dry. Should a perceptible feulness in the subject justify the measure, take away a proper quantity of blood, according to the size of the animal; and, occasionally, put an ounce of nitre in his water, for a fortnight; or, give half a dozen of diuretic balls, as follows:—

Powdered resin . . . . . . . 3 oz.
Linseed meal . . . . . . . . 1 "
Soft soap to form the mass.
Divide into six, and give one every morning the first thing. Should these remedies appear not to assist the cure, and the cracks not heal so fast as desired, then proceed to stronger means.

Cape aloe . . . . . . . 8 drachms.
Calomel . . . . . . . . . 2 "
Form into a mass, with linseed meal and soft soap, and divide into two balls. Give at intervals of about five days, according to the strength of the horse.

SALLENDERS

Are situated upon the fore part of the hock, and are to the hind legs what mallenders are to the fore legs. They originate in the same cause, and are cured by the same means.

WARTS

Are troublesome things on account of the itching sensation with which they are attended. They are, also, extremely offensive to the eye of the owner, especially if they bleed much, besides making it highly disagreeable to ride a horse in such a state. The only means to remove them is, either by ligature, or the knife. In many cases it is necessary to have the horse cast. Some warts are situated in such places, that one has not an opportunity of properly getting at them, without incurring considerable danger. If it be the intention to remove them by ligature, take of—

Arsenic . . . . . . . 1 drachm.
Hog’s lard . . . . . . . 1 "
Mix, and apply to that part of the ligature embracing the wart, once a day; or apply, in the same manner, butter of antimony, anointing the part with the feather-end of a pen. The most effectual manner, however, is to remove them with the knife; and immediately, but slightly, cauterise the part. This has been found to answer better than any other application.

HIDE-BOUND.

This disease has been attributed to many causes, and appears in a want of flexibility of the skin, which is pervaded by a general stiffness, that seems to form an entire adhesion to the flesh, without the least partial separation or distinction. There is plainly perceived underneath the hair, a kind of dusty scurf, that raises it up in different parts, and gives it another hue, the coat, in many places, forming an appearance of two or three colours, and showing at once that the insensible perspiration, which should always be going on, is either retarded, or wholly stopped.

The horse exhibits a general languor, dullness, heaviness and weakness. His excrement is dark, foul, and very offensive. He sweats much upon every moderate exertion, and his coat stares, the hair turning different ways, the effluvium of which is highly disagreeable, and affords evident proof of weakness and debility.

The probable cause of all this is most apparent in bad food, and want of that proper care which the animal requires in the stable. These are the principal causes of this disease; still there are others, all centring in poverty; such as allowing him to feed on the long, lank grass, which is found in low swampy lands in the autumn, and musty hay, or bad oats, which may in some degree allay hunger, but not gratify the appetite; for being in itself destitute of the quality of superior food, it does not sufficiently contribute to the generating of blood, or stimulating the system.

The sources for the supply of chyle being thus obstructed, the lymphatics are deprived of their due proportion of nourishing fluid, and become, not only in some measure contracted, but in a great degree inactive. This, with the want of external care and dressing, contribute to an almost universal obstruction of the cutaneous pores.

Although we have called hide-bound a disease, yet, under judicious management, it is scarcely
THE HORSE, AND

[FAVY]

entitled to that designation, being in fact no more than a temporary inconvenience. To cure it, therefore, take away about two quarts of blood, and in three or four hours after, give a mash of malt, oats and bran, equal parts, continuing the same every night for a fortnight, stirring in it one of the following powders:

Flour of brimstone . . . . . 12 oz.
Antimony . . . . . . . . . . . 1 lb.

Let these be well rubbed together, and divided into twelve parts. Give other feeds, morning and noon, of equal parts of oats and bran moistened with water. If the continuance of the bran should relax his body more than seems judicious, put into his feed a handful of split beans, and the same quantity of chaff. This method of treatment will be found to succeed; but it should be accompanied with regular and substantial dressing, air, exercise, sound good oats, the best sweet hay, and fresh soft water. When by this means, he begins visibly to improve in his hide, coat, and condition, let him have, twice in the week, a brushing gallop, to produce a tolerable sweat, and enliven the circulation, taking great care to let him stand still until he is perfectly cool. Then dress him thoroughly, and persevere in this every night and morning until he is well. Should this method be unattended with success, there must be lurking in the system something else that should be removed. Take, therefore,

Blue pill . . . . . . 2 drachms.
Aloes, Cape . . . . . . 4 "

Give this in the evening, and keep all food from him during the night. In the morning treat as in administering a dose of physic. In the course of four or five days, repeat the medicine, and, if a third dose should be required, which will be ascertained from his appearance, let him have it, taking care that he does not get chilled during the action of the mercury. The following powder has been recommended to be given daily in his food without having recourse to the preceding preparations:

Cantharides, finely powdered . 5 grains.
Pimento . . . . . . . . . . . 5 drachms.
Sulphate of Iron . . . . . . . 2 do.

Should the animal reject his food with this in it, form it into a ball, with treacle, and give it for a week or a fortnight as the occasion may require. In the early part of summer, a good piece of grass will be found of great service.

FAVY.

This is one of those diseases, to cure which, and its co-disease, glanders, the veterinary profession have been more puzzled than with all the other diseases to which the horse is liable. For a long period the cause of this complaint was hidden in obscurity. All old writers said it was something the matter with the blood, but could not tell what. The French studied the disease, and its nature, but still little progress was made towards elucidating its cause. We are now, however, in a position to be able to define the disease in a much more enlightened form, although its cure cannot at all times be effected.

Farcy may be defined to be an inflammation and suppuration, attendant with ulceration of the absorbents of the skin. It was formerly thought to be a disease of the veins, but this is not the case. Its seat or locality is in the superficial absorbents of the skin covering the veins. Were it otherwise, the veins would ulcerate and open, and considerable bleeding take place. Externally, the skin may be said to be the only visible part susceptible of farcy; but when the disease becomes violent the lungs partake also of it. Every part of the skin is susceptible of the disease, but not all parts equally so. Wherever the skin is thinnest, there it is much more liable to become affected than where it is thick.

The commencement of the disease is generally accompanied with swelling and inflammation, and, at length, a single tumour appears. This goes on until matter is formed, suppuration takes place, and of course ulceration. The tumours do no always suppurate, but often become hard and shirrions. These, in the old farriers' language, are called "buds, or farcy buds;" there are frequently many of them, forming a kind of chain enlarging to an alarming degree. Such are the common symptoms and appearance of the disease. It takes place most frequently in the hind legs.

There is a poison connected with this disease, which, if applied to the skin of a sound horse, will produce inflammation and matter of the same kind; and if the matter becomes absorbed, it will, in all probability, produce
Farcy.] MODERN VETERINARY PRACTICE. [Farcy.

glanders. But in all cases this might not occur, as there are some constitutions much more susceptible of disease than others.

However, this experiment proves the matter to be contagious, because it is possible to produce it on a healthy animal. There is another curious fact connected with this poisonous matter. If it is inserted deep below the skin, it does not produce farcy; but is absorbed into the system, and may produce glanders. In this case the absorbents do not inflame, which would prove farcy to be a skin disease, in which the deep-seated absorbents become affected, and the superficial ones not so. From this cause, if a horse with farcy were to be flayed at this stage of the disease, there would not be the least appearance of it under the skin; nor can it be produced in a sound horse without an abraded surface. It may be produced, however, if applied to the membrane of the nose of the animal in such a manner as not to abrade the surface. Professor Coleman's opinion is, that one horse in a stable cannot communicate it to another, without an abraded surface. This would seem to prove that it is generated, and that constitutional diseases cannot be produced except by contact. If poisoned atmosphere be inhaled, disease may be propagated by breathing it, whilst contagion requires the actual contact of the diseased animal; though there is little or no distinction, for the poison does not come in contact with the lungs under infection. Such diseases are mostly the effect of crowded and filthy stables, and such as are contagious may be produced without contact.

With regard to farcy, it has been questioned whether one in one thousand ever becomes affected by the actual touch of this matter, showing clearly that it is not a local disease. Formerly it was thought by some to be caused by drinking cold water, and eating beans; but it is more likely to be produced by a poisoned atmosphere—an atmosphere over and over again impregnated with what escapes from the lungs, the skin, the dung, and the urine. During the French war, when an expedition was despatched to Quiberon, the horses which were shipped on board the transports had to be closed in under the hatchways, so that the poor animals were well-nigh suffocated with heat. The consequence of this was, that when they were disembarked, nearly every one of them was either farced or glandered.

Pure air is so important to life, in every condition, that even the strongest animal, if deprived of it, soon exhibits symptoms of distress. Farcy, therefore, is a consequence of an impure atmosphere, and is intimately connected with glanders. "They will run into each other," says Mr. Youatt; "or their symptoms will mingle together; and before either arrives at its fatal termination, the other will generally appear. An animal inoculated with the matter of farcy will often be afflicted with glanders, while the matter of glanders will frequently produce farcy. They are different types of the same disease. There is, however, a very material difference in their symptoms and progress; and this most important one of all—that while glanders is incurable, farcy, in its early stage and mild form, may be successfully treated."

The same writer further adds, that farcy, like glanders, springs from contagion and bad stable management. "It is produced by all the causes which give rise to glanders, with this difference—that it is more frequently generated, and sometimes strangely prevalent, in particular districts. It will attack, at the same time, several horses in the same ill-conducted stable, and others in the neighbourhood who have been exposed to the same predisposing causes. Some have denied that it is a contagious disease. They must have had little experience. It is true that the matter of farcy must come in contact with a wound or sore, in order to communicate the disease; but accustomed, as horses are, to nibble and play with each other, and some as the corners of the mouth are frequently rendered by the bit, it is easy to imagine that this may be easily effected; and experience tells us that a horse having farcy ulcers, cannot be suffered to remain with others without extreme risk."

Horses most predisposed to farcy, are those that are narrow-chested, with flat sides and long legs. Common farriers say they can cure the disease, because they think it is a merely local affection, and consequently easily treated. In this belief, they burn the ulcers, and may, in some instances, perform a partial cure, if the poison has not thoroughly pervaded the system. But in most cases, when thus locally treated, it breaks out again even at the end

20
of twelve months, and sometimes terminates in ganglions. When the lungs are not touched, a cure is sometimes effected by such treatment. If the disease is purely local, as when the buds are on the legs only, indicating that it is confined to the lymphatics of the skin, the disease may be reduced; but if the poison has got into the system, a perfect cure may, in general, be despaired of. The probability, however, of expelling the disease will depend upon the circumstance of its being local or constitutional; and, if the latter, to what extent the system has been affected by it. Should the membrane of the nose have become at all ulcerated, or the membranes lining the bones of the head, have begun to secrete and discharge a disagreeable matter, the chances are a hundred to one of succeeding in a cure.

If the horse should be in tolerable condition he should be immediately bled, according to strength, size, and constitution; and the following ball given to him:—

| Cape Aloe | 8 drachms |
| Ginger | 1 do |

Form with soft soap.

Treat as directed in administering doses of physic. Should the farcy buds diminish, or no increase take place in those which are formed, give a second dose of medicine, and treat as before. The next thing to be done is to lay the farcy buds open. These will be found principally on the inside of the hind leg, frequently down the neck, in the line of the jugular vein, along the back, and frequently on the face. When found in this last, the cure is always doubtful. Some persons open the buds with a lancet, and apply the actual cautery, to destroy at once by fire what is imagined cannot be done any other way: but objection has been taken to this mode of treatment. It is better first to open all the abscesses with a lancet, after squeezing out the matter, which must be exceedingly carefully done, for the pain the horse experiences when undergoing this operation makes him very fidgety; and it is sometimes attended with great danger. After all the matter is cleared away from the sores, a little sulphate of zinc should be applied to each of the opened buds. This application will be found highly beneficial on first opening the buds. If this has been done in the morning, let it be again repeated at night; then on the morrow, wash the sores well with the following lotion.

| Extract of Saturn | 2 ozs |
| Spirits of Wine, campherated | 8 do |
| White Wine Vinegar | 1 pint |

Mix well together, and keep it close stopped for use; then take of—

| Prepared Antimony | 1 lb |
| Sulphur | 12 ozs |
| Cream of Tartar | 8 do |

Incorporate well in a mortar, and divide into twenty equal parts, giving one part every night in his corn, first sprinkling with water to insure the adhesion of the powders. This proportion is meant for the distemper in its mildest state, when the buds have made their first appearance.

Should the distemper be in a more advanced stage, bleeding should be repeated, in a proper time and in a moderate degree; and upon the scabs or eschars peeling from the buds, they should be occasionally washed well with the following:—

| Corrosive Sublimate | 2 drachms |
| British Brandy | ½ pint |
| White Wine Vinegar | 1 do |
| Tinct. Myrrh and Aloes | 2 ozs |
| Water | ½ pint |

First dissolve the sublimate in the brandy, then add the other articles, and shake well together; or, take

| Sugar of Lead | 1 oz |
| Sulphate of Zinc | 1 do |
| White Wine Vinegar | 1 pint |
| Water | ½ do |

Mix together.

For internal medicines, an immense number have been tried, and some with excellent effect; but the variety being great, the right one is not at all times chosen. The following formula, however, has been found excellent.

| Cantharides | 5 grains |
| Arsenic | 4 do |
| Sulphate of Iron | 1 drachm |
| Gentian | 1 do |
| Ginger | 1 do |

Form into a ball with soft soap.

Give one every morning, first thing. Or,

| Corrosive Sublimate | 4 grains |
| Sulphate of Iron | 2 drachms |

Form into a convenient-sized ball, with linseed meal and soft soap.
Give every morning. Or,  

Blue Pill  2 drachms.  
Aloe  1 do.  
Ginger  1 do.

Mix together for one ball, with a little oil of turpentine, and give one every second morning. Great care must be taken to watch the horse that he does not become salivated. If either of the foregoing prescriptions should appear to take his appetite away, let him remain for a day or two, without giving him any of them. Whilst administering these medicines, the horse should be well kept, and fed without stint. An ounce of nitro may occasionally be dissolved in his morning water, as he will then be most likely to drink. A little green meat will be good for him; and when he is getting better, give him a run at grass in some place handy, and a feed of corn morning and evening. Speared malt is excellent at this time; also, about a teacupful of linseed poured into a quart of boiling water; mixing with it, eight or nine good potatoes, well boiled and worked up together. This may be given with his corn at his mid-day feed. He may, at first, refuse to take it; but this dislike will, by a little perseverance, soon be overcome, when the benefit that will arise from it will be, at once, apparent. Carrots are very good, chopped up fine; also turnips of the Swedish kind, as they contain more saccharine matter than any other; also parsnips; but of these, a few only should be given at a time; for, if given in quantities, they are apt to cause gripes. The treatment, as practised at the Royal Veterinary College, is by administering from two to five drachms of sulphate of copper, in solution, in about a pint of water; increasing or decreasing the dose, as circumstances may require; and also applying to the sores daily a solution of the same sulphate, in the quantity of two ounces to a pint of water. In the recent edition of White's Compendium of the Veterinary Art, edited by Mr. Spooner, that gentleman says, that the treatment of farcy "must be very similar in its nature to that recommended for glanders, but with a much greater probability of success. The system must be supported by a generous, though not too stimulating, diet, and the vegetable and mineral tonics administered as in glanders; but, if the sulphate of copper be employed, two or three drachms will be a sufficiently strong dose. Carrots or green food will be a useful addition to the diet. The buds should be opened with a lancet, and, when the matter is evacuated, a caustic should be applied to the ulcers. The lunar caustic will form a useful application; but other caustics may be employed. An ointment composed of two drachms of hydrate of potash; lard, or palm-oil, two ounces; mercurial ointment, two ounces, should be rubbed daily in the course of the enlarged lymphatics. The horse should be exercised daily, and properly groomed; and the above treatment continued until all symptoms of farcy entirely disappear." In the Materia Medica there is a better form of this ointment, in which the mercury and the iodine are chemically combined.

The same gentleman observes that the most favourable symptoms presented by this disease are often delusive; for even when it appears to have succumbed to the skill of the practitioner, it breaks out again and again, and sometimes, when the morbid poison has thoroughly penetrated the system, after many months, it will make its appearance in the form of fatal farcy or glanders.

Mr. Blaine tells us of a horse so dreadfully afflicted with farcy that it was unable to stand, when it was drawn into a field of tares, and left there to take his chance. When the poor brute had devoured all that was within his reach, hunger forced him to search for more; and managing to crawl along, and eat as he went, he eventually recovered.

The dinioelide of copper has been introduced by Professor Morton, and beneficially used in farcy, as well as in such other diseases, as have a resemblance to glanders. It is usually combined with the root of gentian, to which small quantities of cantharides may be added with advantage. When an increased soreness of the diseased parts appear, its application should cease for a time, although this is an indication of the absorbent vessels being stimulated into increased action.

Water farcy is entirely different from the common farcy, of which we have here been treating, and is spoken of in another part of this work.
CHAPTER XIV.

SWELLINGS AND TUMOURS.—WINDGALLS; BOG-SPAVIN; THOROUGH-PIN; CAPPED HOCK; SEROUS ABSCESS; TUMOUR ON THE KNEE.

WINDGALLS.

Windgalls consist of a kind of cyst, or sac, attendant on most, or all joints, and frequently occasion lameness, and, if not this, they are a great eye-sore. These sacs are situate on both sides of the tendons, just above the fetlock joints, on the fore, and not unfrequently on the hind legs likewise. They become enlarged, generally, from hard work, causing a greater determination of blood to the part, and continue to increase until they become disagreeably large. It is from this circumstance, that liniments, or lotions, are applied to them to reduce them, and this apparently takes place; but when the animal is again put to work, they as certainly begin again to enlarge, and when they grow to the disagreeable size we sometimes see them, they never again contract, so far as to allow the affected part to assume its original form.

For the cure of these unsightly things, liniments, lotions, and even blistering have little or no effect. Perhaps the best plan to be adopted is first to clip the hair off all round the leg, over the fetlock joint, and about three inches above the seat of the enlargement. When this is done, the whole of the clipped part should be well rubbed with mercurial plaister, thoroughly melted. This should be effectively applied with a paint-brush, and none of the parts overlooked. This done, a flannel bandage, about three yards long, and about three inches broad, should be bound tight round the leg, and allowed to remain so situated for a fortnight; when by clipping it with a pair of scissors down the front of the leg, it may be allowed to fall off, and the limb be set at liberty. A cradle must be used. Should this mode of treatment not be found effectual, the parts may be fired, or the bursæ opened in the following manner:—Have the horse cast, and with a pretty large abscess-lancet lay open the enlarged bursæ at bottom, or lower part, to such an extent as to enable the finger to be introduced, which should be done and turned in it several times. This will break the membrane of the sac. Then put a suture in the wound, and draw the lips of it together, and allow the animal to rise. This treatment will, at first, cause some little swelling, which should be bathed well with warm water, two or three times a day, and a bandage applied. When the inflammation has considerably subsided, treat the puncture as a common wound. If the case is a bad one, and the windgalls very large, so soon as the inflammation has subsided, cast the horse again, and fire the parts, which has been found to act very successfully. The horse should have a loose box, and a dose or two of physic, during the time he is resting. In the treatment of these enlargements iodine and mercurial ointments have been advantageously used in proportion of three parts of the former to two of the latter. Blistering causes their disappearance for a time; but, with work, they are sure to return.

BOG-SPAVIN

Is a disease, very common where there is hard work, especially in young horses, when they have been too early used. The hock is liable to more diseases than any other joint belonging to the horse; it being designed for very extensive motion; but the motion of it, during natural labour, is very different from that which occurs when an animal is thrown upon his haunches, or pulled up suddenly, or when taking high and wide leaps. These violent motions of the joint, are, as may well be supposed, likely to produce disorder. Bog-spavin, then, is an enlargement of the mucus capsule, situated immediately in the bend of the hock, and near to the superficial vein, passing obliquely over the part; in fact, it may be said to be a corresponding disease to windgalls in the fetlock joint. It does not always produce lameness; but, when so large as to do this, and prevent the horse from working, the tumour should be immediately opened as
CAPPED HOCK.

directed in windgalls. Great care, however, must be taken not to puncture the vein, which may be easily prevented, by tying a fillet of tape round the bottom part of the thigh. This will enable the course of the vein to be discovered, and, consequently, avoided. Having made the puncture, and found out the mucus, put into the wound a little sulphate of zinc, and proceed in all other respects as described for windgalls.

The editor of The Horse says, that the old and absurd method of passing a ligature above and below the enlarged portion of the vein, and then dissecting it out, is not in the advanced stage of veterinary science practised by any surgeon who regards his reputation; it being merely the consequence, not the cause of the disease. The only method of relief which holds out any promise even of temporary success is exciting considerable inflammation on the skin and thus rousing the deeper seated absorbents to carry away the fluid effused in the enlarged bag. For this purpose, blisters or firing may be tried; but in the majority of cases the disease will bid defiance to all appliances or will return and baffle our hopes when we had seemed to be accomplishing our object.

Where there is bog-spavin the horse should only be used for ordinary work. Hard or rapid work is out of the question.

THOROUGH-PIN

Is a bursal enlargement, situated in the upper and back part of the hock, the tumour showing itself on either side; hence its name, thorough-pin. This seldom occasions lameness. It is caused by over-weighting, immoderate riding, and ill-management in the breaking of young horses.

For its treatment proceed precisely as directed for windgalls and bog-spavin.

"I have," says Professor Spooner, "known a troublesome and obstinate lameness produced from the upper thorough-pin, or perhaps rather from some strain of the tendon which attended it. It gave way, however, at length, to a seton placed over the part—not through it. I have also succeeded in removing a very large thorough-pin in the lower situation in a high-class race-horse, by the long-continued application of equal parts of iodine and mercurial ointment; previously, however, stimulating the part with a mild liquid blister. The subject was a race-horse of great value, and the thorough-pin entirely disappeared in about two weeks. In such cases the synovial fluid in the thorough-pin coagulates, and becomes organised and firm."

CAPPED HOCK

Is a large swelling, rising at the point of the hock; and although seldom detrimental to the action of the horse it is, however, very objectionable to the eye. It is produced chiefly by kicks, lying on hard stones, or other injuries to which the point of the hock is so very liable. It is sometimes hereditary. This may be taken as proved from the following fact. A veterinary surgeon was called in to see a horse, and was, at the same time, requested to look at a brood mare, and two of her colts, lying in a field close at hand, which were considered of excellent make and form. The dam was a known good one. She was a light chestnut mare, and the colts were of the same colour, one a three-year old, but the other a yearling; and all three, dam and colts, were affected with capped hocks. There had been a colt, which would then have been two years old, but it had been dead about six months, and he had capped hocks too. These were all got by different horses. This goes a great way in proving that like begets like.

If capped hock is not relieved soon in its early stage, it frequently becomes of considerable size, and what is strange, the skin seems to thicken as it becomes larger.

In treating for it in an early stage repellents such as the following should be used—

Sal.ammoniac . . . . . 1 oz.
Spirits of Wine . . . . . 1 do.
Vinegar . . . . . . . . . 8 do.

Rub some of this lotion on the point of the hock, night and morning. Should this not promote the absorption of the fluid, introduce setons on each side of the hock, and keep the discharge up for a fortnight, dressing every day with digestive ointment, composed of

Common Turpentine . . . . . 4 oz.
Hog's Lard . . . . . . . . . 4 do

Melt together over a slow fire, and dress the setons with it, when these are changed every morning.

Should this not have the desired effect at
once, puncture with a lancet, and fire in the manner represented in the engraving, entitled Capped Hock. Whilst using the above remedies, give a mild dose or two of physic.

**SEROUS ABSCESS.**

This kind of tumour is produced by various causes, and is situated at the point of the elbow. It sometimes grows to an amazing size, even to that of a child's head. Serous abscesses are not always alike in their contents, some of them containing a yellowish fluid, and that in a considerable degree. This may be discovered by the undulating feeling they have when pressed between the thumb and finger. Others are hard, will not yield to pressure, and sometimes approach to callousity. Both kinds are generally produced in heavy dray-horses by their lying down on rough paved stables, and frequently when they double their fore feet up under them. The large calcins of the shoes then just come in contact with the point of the elbow, and a bruise will produce them. They may sometimes be caused by kicks, but this is not usually the case. If it were so the horse would instantly go lame, whereas by bruising gradually, the disease continues growing, and may produce lameness.

In treating for these tumours, supposing they contain the serous fluid, take up the skin in the most dependent part, and make an orifice with the seton scissors to let out the fluid. Then insert the finger, as if preparing to place in a tent, which should be done with tow, smeared over with the following digestive ointment:

No. 1.

- Sulphate of Copper, finely powdered . 1 drachm.
- Common Turpentine . . . . . . 2 ozs.
- Hog's Lard . . . . . . . . . . . . . . 4 do.

Melt the turpentine and the lard together and when nearly cold, sprinkle in the sulphate of copper. Or,

No. 2.

- Red precipitate . . . . . . 4 drachms.
- Common Digestive Ointment . 4 ozs.

What is here meant by the common digestive ointment, is the turpentine and hog's lard alone.

This will promote a healthy discharge, if the first recipe does not. Keep this open for a week or nine days. If the parts should swell much, foment them three or four times a day, with flannels dipped in hot water, until the swelling abates. Professor Spooner treats this tumour in the following manner. "If the collection of fluid be not extensive, we may first endeavour to disperse it by external stimulants; in this attempt, however, we shall generally fail, when we must evacuate it by making a considerable opening, so as to admit a free escape of the fluid, which will again form; or what will still be better, we may insert a seton through the tumour. After this a solution of blue or white vitriol should be injected, so as to stimulate the sides of the cavity and produce an altered action. After some time pus will be secreted instead of serum, and then the part will soon get well."

The hard kind of tumour must be treated in another way; and the only way it can be, to be effectual, is, at once to make an incision down the middle of the tumour, and dissect it completely out, then insert a pilet of tow, smeared with No. 1 ointment above, and sew up the wound until within an inch and a half of the bottom, which orifice must be kept open during the suppurative process; but when that has stopped, dress as for a common wound, with compound tincture of myrrh.

**THE KNEE.**

Sometimes enlargements on the knee take place, but they are of little consequence.—A tumour about the size of a walnut formed on the knee of a horse. It was punctured with a very small abscess lancet, the matter squeezed out, the part blistered, and the horse ordered to be turned out. In a month, he came up, and no person could discover the place that either the puncture or blister had made. The horse was of great value. The same line of practice we would recommend in all similar cases, as it is simple, and not likely to be attended with much danger; whereas a more complicated course might be followed by evil consequences. Where a simple mode will effect our object, it is always best to adopt it.

CHAPTER XV.

THE EYE AND ITS DISEASES.

THE EYE IN GENERAL.—THE MUSCLES OF THE EYE.

In speaking of the muscles of the eye, the orbicularis first comes under our notice. This muscle surrounds, and is attached to the bones of the orbit. It passes under the loose skin of the upper eyelid, which has great motion; and its office is to close the eyelid perfectly, or to assist in performing the involuntary act of winking. The antagonistic muscle to this is the levator palpebrae, rising from the posterior part of the orbit, and passing over the orbit, contiguous to the tarehymal glands, which are placed in the hollow of the orbit above the eye. This pair of muscles is in almost unceasing action, and like all other muscles would become weary; but by acting in opposition they obtain intervals of rest. Thus, when the eyes are shut, the orbicularis is in action; but when awake, the levator palpebrae. This last, however, is relaxed by the act of winking, which is clearly one intention of winking: another is to allow the tears to pass over the orbit for the purpose of removing extraneous matter, by means of the action of the eyelids.

To accomplish the various movements of the eye, there are four straight muscles, two oblique, and one retractor, or drawing-back muscle, the powers of which are very superior to those in the muscles of the human subject. Returning, however, to the straight muscles, we commence with the levator ones, which rise from the posterior part of the orbit, pass over the retractor muscle, and are attached to the sclerotic coat. They are for the purpose of directing the eye upwards. The eye always acts in unison with these muscles. The next are the abductor, which originate in the posterior part of the orbit, and are inserted into the anterior part of the sclerotic coat on the outside. These direct the eye from the nose. The depressors rise in the posterior part of the orbit, and are inserted into the inferior part of the sclerotic coat. The adductors have the same origin, and are inserted into the sclerotic coat towards the inner canthus. All these muscles acting together, have the power of drawing the eye into the orbit; but their action is inconsiderable.

The oblique muscles are two. One takes its rise from the inferior part of the orbit, and is inserted into the sclerotic coat below. The other, called the trochlearis, also rises in the same part, and going through a pulley-like adaptation, is inserted into the anterior part of the sclerotic coat, and thus draws the eye forward. The principal use of these muscles is to act in opposition to those which are straight, by drawing the eye forward.

The retractor oculi, rising from the superior part of the orbit, surround the optic nerve, but are separated from it by adeps (i.e., fat); and that the fibres may not affect the nerve, they are not attached to the sclerotic coat, where the nerve emerges. Here we may mention how the inner and outer canthus may be distinguished. When the eyes are separated from the body, it is the broad side which forms the inner canthus, over which the haw plays.

In the structure of birds, for example, there is an organisation somewhat similar to the haw in the horse, called the membrana nictitans, a semi-transparent membrane, having a muscle and a tendon. In the horse this is cartilaginous, edged with black, at the anterior part fastened to the conjunctiva by the cellular membrane; and if an attempt is made to pass the finger between the eye and the haw, the action will be prevented by the conjunctiva, showing that the conjunctiva is a reflected membrane over the cellular attachment. The haw is divided into two parts. The anterior part is convex on the outer surface, and concave on the inner, to fit the convexity of the eye. The haw acts as a kind of shield; but not being sufficient to cover the whole orb, whilst in its natural situation, the retractor muscle acts first, by which means the ball of the eye presses upon the adeps, and the haw, in consequence, is forced
over the eye, showing that it has no separate movement, but is dependent on the retractor muscle, and performs its functions by moving a part to which it is least attached.

The lacrimal glands are placed above the levator palpebrae, lying close to the sclerotic coat, and moisten the eye.

The eyelids are peculiar in the horse. The bottom one has no lashes, but the upper one has a double row in the centre, but not extending from canthus to canthus. They are seldom diseased, or even the cause of disease.

The conjunctiva is immediately connected with the eyelids, the haw, and the orbit. It possesses three different structures; that is, three separate degrees of vascularity. It lines the inner surface of the eyelids, and covers the eye-ball, being reflected over every part. This membrane is highly vascular in that part which lines the eyelids, and is less so over the opaque cornea, and still less over the transparent cornea, never admitting red particles of blood, unless in a state of inflammation. The eyelids possess a secretion of their own, to protect them from the tears, which, though congenial to the eye, are not so to the edges of the palpebrae. It is a well-known and somewhat singular fact, indicating the different degrees of susceptibility to which different parts of the animal structure are liable—that the salt that is in tears will at any time inflame the cheek, but not the eye; whilst warm water applied to the eye, will inflame it, and be congenial to, and relieve the cheeks.

The apparent use of the eyelid is to protect the eye from foreign matter, and also to regulate the admission of light. Independent of these, the inner surface of the upper eyelids, covered by the conjunctiva, is connected with the tears, which flow between the eye-ball and the lid, the conjunctiva being thus prevented from coming in contact by a fluid. The eyelids also secrete a fluid of their own, which prevents any tendency to irritation. The action of the lacrimal glands is carried on, at intervals, even in sleep, though there may be but little wanted; but any foreign matter, even the wind, will excite their action. This is occasioned by the nerves of the eye-ball being irritated, and the tears, in consequence, being thrown out to alleviate such irritation. Between these glands and the mental character of the horse, there is also great sympathy; and when their action is excited, so that the secretion has become too great to be carried off by the nose, the tears flow over the cheeks, which constitutes weeping. This secretion is also affected by the action of the retractor muscle, which, operating with the adductor muscle, the eye-ball is brought to the inner canthus, and the haw forced over the eye-ball. Extrinsic matter very seldom occasions blindness; for the tears and the eye-ball moving in one direction, and the haw in a contrary one, any such matter is quickly dislodged.

The use of tears is to keep the parts moist and transparent, and to remove the waste from evaporation, which is always going forward in moist external surfaces. Having performed their office of lubricating the eye-ball, and the parts attached, they pass into the duct, called puncta lachrymalis, situated at the inner canthus of the eye. This duct in the horse is little larger than in the human subject, and passing through a canal, partly bony and partly membranous, terminates at the lower end of the nostrils, much increased in size. The construction of this junction in man is much more complicated than it is in the horse, and is very frequently subject to disease by becoming obstructed. In the horse this very seldom occurs; and when it does, it is attended with but very trifling inconvenience.

The action of the haw takes place from any cause which produces pain or inflammation; and this may be continued so long, that the retractor and adductor muscles will permanently contract, when the haw, being completely powerless of itself, is left protruded out. When this is the case, there is no difficulty or danger in cutting it out with a pair of scissors.

In the horse there is no opaque cornea visible; whilst in man, it constitutes a prominent feature of the organ; and although it does not appear to give any additional perfection to the vision, it adds greatly to the beauty and expression of the eye.

The transparent cornea is more or less convex in all animals. In horses, it is not circular, but horizontally oblong, being more contracted at the outer than the inner part. The ball of the eye is also denser and more transparent. By a law of optics, the rays of
light pass through a transparent convex body, and become bent, whilst conveying objects to a focus, which again conveys them to the retina, thus constituting vision. In some men the cornea is frequently too convex, in consequence of which the rays of light are brought to a focus before they reach the retina. This constitutes near-sightedness; the reverse taking place with old people, the cornea being too flat. Of defective sight in the horse it is more difficult to judge; but there is no doubt that many horses with prominent eyes, and very convex, have imperfect vision, as they, invariably, are very apt to shy, or to start.

In examining the eye, and looking into the anterior chamber, which contains the aqueous humour, the iris appears, the centre of which is perceived in the opening called the pupil. Looking steadily at it, there is a blueness apparent, showing that there is free access to the back part of the eye through the pupil, and also showing that the iris divides the humours of the eye into two spaces, which are called the anterior and the posterior chambers. The iris appears to hang as a curtain between the cornea and the crystalline lens, and is composed of two orders of muscular fibres. It demonstrates the colour of the eye; as, for instance, when it is black, or blue, it forms an eye of the same colours. In bay horses it is of a cinnamon colour. Sometimes it is white, constituting a wall eye, with which there are generally associated white hairs on the eye-lashes and orbit. The colour of the outer part of the iris is no criterion for the posterior, which is generally black, and is the part that is of service to the sight of the animal. The shape of the iris, at the circumference, is oblong, like the transparent cornea. It is very muscular, and its fibres are radiated, and wound round the circumference with another order of muscular fibres. Another order winds round the inner margin, and the union of the two is by the radiated expansion of one order of fibres and of the blood-vessels.

The opening of the iris, or the pupil, is not a solid body, but a passage left for the rays of light to penetrate to the posterior chambers of the eye. The iris undergoes many changes, as to size, in all animals. In the horse it changes its form, from round to oblong, and vice versa.

In cats, the changes are well seen; for, in a strong light it becomes extremely oblong, but perpendicular; whilst in the horse it is horizontal. The object of this adaptation is at once obvious. In order to secure its prey the cat has to look upwards and downwards, but not laterally; whilst the horse has to look in all directions; so that, although the pupil becomes horizontal, it is never very narrow. There is also, in the horse's eye, a peculiarity of structure which seems to have the power of excluding light. This is effected by four glandular bodies, two placed at the lower edge of the upper margin of the iris, and two at the lower margin. These are not seen in a weak light, when the pupil is large; and seldom in the dead subject; but make their appearance in prominent eyes, under a strong light. They are black, and covered with the nigrum pigmentum, or black paint, which, in the dead eye, becomes a mucous. These bodies may almost be called an internal eyelid, and, united to the iris, they complete the curtain.

By observing the effect of different degrees of light on the iris, it will be seen that it becomes stimulated by the action of the rays, and expanding, through the nervous energy, makes the pupil much smaller. On the other hand, if the iris contract, the pupil appears so much larger. This portion of the optical organ is possessed of an abundance of nerves and muscular fibres. The muscular fibres are of two orders, the one appearing a kind of sphincter—signifying to shut up—at the inner margin, and which when excited by a strong light, at the same moment, contracts. The transverse order relax and elongate, and thus the pupil is diminished. The stimulus of light being removed, the transverse preponderate and diminish the iris, whilst they enlarge the pupil. It would appear that the circular or sphincter order, require a very strong stimulus to be able to overcome the constant superabounding power of the transverse order, the varied action of the pupil taking on different forms, according to the strength of light. In a weak light these become circular, from the transverse fibres being in full play; but, as in a strong light the pupil becomes oblong, it would appear that the transverse fibres have not an equal power of relaxation, except at the top and bottom; for, at the corners, they scarcely relax.
at all. There is considerable sympathy between the iris and the retina, as in cases of 
gutta serena, or glass eyes, as it is termed; or when the optic nerve and the iris have lost
their sensibility.

In considering the outer coats of the eye, we will commence with the sclerotic, which is
composed of tendinous material, very dense, but not equally thick all over, the thickest
part being its posterior. This part, as it receives more pressure against the orbit, when
under the influence of the retractor muscle, nature has proportioned the means to the end,
and made it thicker, in order that it might be capable of repelling the pressure it was destined
to receive. Anteriorly, there is a groove receiv

ing the posterior edge of the transparent cornea, called the ciliary processes—the white
folds at the margin of the uvea in the eye, covered with black matter; there is a passage
through the sclerotic coat for the optic nerve, which does not pierce it at its centre, but
pierces the sclerotic and choroid coats at the inferior part.

The choroid coat is on the inner side of the sclerotic, and is very vascular, possessing many
blood-vessels, nerves, and absorbents. Its appearance varies in different animals. In white
ferrets, and also in those classes of persons commonly called "albinos," with long white
hair, the colouring matter is wanting, and the arteries of the coat are alone seen. The con-
sequence is, the bottom of the eyes look red. Where this formation exists, there is an inca-
pability of seeing in a strong light, objects being best seen in the dark, which is most
properly called a diminution of light; and in sympathy with such, the eye-lashes are always
white, and the hair of the head white also. Frequently in smaller animals all the hair is
white, as we find in white mice and white rats. In man, generally, both surfaces of the choroid
coat, the one in contact with the sclerotic coat, the other with the retina, are covered with
a black pigment, which, in the dead animal, becomes a kind of mucus. But here there is a
difference according to circumstances. Negroes have it much blacker than the inhabitants of
temperate regions, and have a power of absorbing superfluous rays of light, to an extent
that renders vision even painful. This coat, in horses, is of great importance. All the
pigment or colouring matter below the optic nerve, being about one-third of the whole, is
black, but above it is green and blue, which are separated from the other by a distinct hue.
This compound, in the living eye, imparts to it the appearance of sky-blue, which, seen through
the humours, is of a greyish hue. Horses fre-
frequently, and by very eminent men, have been pronounced unsound from having this grey
cast or shade in the eye. The optic nerve
having pierced these two coats within, the
black covering is lined here with a little pig-
ment. It is then distributed over the whole
of the surface, as far as the junction of the
opaque cornea with the ciliary processes. The
object of this variegated coat, and why it should occupy the superior part in particular, is, that
the rays of light may pass through the nerve going beyond the retina. In man, from the
colour of the pigment, the rays become ab-
sorbed, and terminate accordingly; but in a
pigment that is not black, they do not termi-
nate, but are reflected back, striking the nerve
a second time, and the effect is then an in-
creased degree of vision. In the horse, the
rays strike the nerve twice, but only at the
upper part, where the green pigment is situated.
The rays thus received are obviously the weak-
est, especially when the head of the animal is
near the ground, which is his natural position
when in the act of grazing; the black pigment
then receives the strong superior rays; and
thus by a skilful combination the light is equalised, and sharp keen sight produced.

"The reader may see in the dusk, or even
when duskiness is fast yielding to utter dark-
ness," says Mr. Youatt, "the beautiful sea-green
reflection from the eye of the horse. . . . If
the reader has not examined this beautiful pig-
ment, he should take the earliest opportunity of
doing so. He will have a beautiful illustration of the care taken by the Supreme Being that each
shall suit his situation. The horse has not the
intelligence of man, and may not want, for any
purpose of pleasure or improvement, the vivid
picture of surrounding objects which the retina
of the human being presents. A thousand
minute but exquisite beauties would be lost
upon him. If, therefore, his sense of vision
may not be so strong during the day, it is made
up to him by the increased power of vision in
the night."
The crystalline lens is not exactly a perfect lens, the anterior side being rather the flattest. It is contained in a perfect capsule or bag, a fluid separating the capsule from the lens, which is called the liquor morgagni, from M. Morgagni, the name of its first discoverer. This capsule does not adhere to, but is confined in its position by the tunica vitrea, being reflected over its edge, at which part, also, it is surrounded by the choroid coat, formed into folds, called the ciliary processes. It was formerly doubted how these parts grew; but doubts were dispelled on its being discovered that arteries and veins are situated in these parts. The lens is not only flatter anteriorly, but is not of the same structure throughout, the outer surface being like a mucus or jelly; whilst within, it becomes harder, even to the centre. From this arrangement the rays of light are bent from one degree to another, in proportion as they approach the centre—the crystalline lens acting as a refracting glass, receiving the rays, in some measure refracted by the cornea and aqueous humour, and bringing them to a focus on the retina.

"When either the cornea or the crystalline lens is too convex," says Mr. Spooner, "the object is brought to a focus too soon, and vision is indistinct, and the person near-sighted." This, he adds, as we have already observed, is a frequent defect in the eyes of horses that shy, in which we often find full google eyes. When, however, the cornea or the lens is too flat, a contrary effect is produced, and the object is not converged soon enough. This is often a complaint in old people, who are relieved by convex glasses, whilst the former defect is relieved by concave lenses.

The iris has an involuntary power of changing under different degrees of light. It also has another power independent of the effects of light—namely, that of looking at a minute object, though the light be weak, and becoming larger as the pupil gets smaller, and vice versâ. The pupil being small, the rays are confined to such as proceed from the object alone. Thus there is no confusion of images on the retina, but the smallest object is seen; and, as in the last instance, when the object to be seen is large, the iris contracts, that the rays may be admitted from all parts for a perfect representation.

In examining the ciliary processes, they are nothing more than a continuation of the choroid coat which surrounds the capsule of the crystalline lens. They are called choroids, and are the actual foldings of that membrane. Their object is to prevent the passage of any rays of light on the outside of the lens, which otherwise would render vision imperfect.

The vitreous humour is of a peculiar composition. Although it seems to be a kind of jelly, it is not; but nearly of the same fluidity as the aqueous humour. This appearance arises from its being contained in cells, and not in a single capsular bag. A proof of this is found in the breaking of the cells, when the fluid drops freely. It is also admirably formed; for being in contact with the expansion of the optic nerve, it cannot alter its position, or be injured by pressure.

The phenomenon of vision is both curious and grand. In the first place, all objects to be seen require a sufficient quantity of light to render the optic nerve sensible. Although different animals require different degrees, man requires the most—a fact demonstrated by the construction of his eye, which has a small transparent cornea, and a black pigment. The vision, to be perfect, must be painted on the retina; and here is a curious fact, that though we have two eyes, we see only one object; yet there is an object painted on each retina, but only one on the sensorium. Being possessed of only one sensorium, so long as the object is the same, there is only one impression formed; but immediately objects change, there are different impressions formed. All objects on the retina being painted upside down, the rays of light cross each other, and meet in a point near the lens, when they proceed through the vitreous humour nearly in the same right lines.

Objects presented to the eye have their images painted on the black part of the retina, the rays of the incident pencils converging to their proper foci there, by the refraction of the different humours; and for this office they are admirably adapted; for as the distance between the back and front of the eye is very small, and the rays of each of the pencils that form the image fall parallel, or else diverging on the eye, a strong refractive power is necessary for bringing them to their foci at the retina: but
each of the humours, by its peculiar form and
density, contributes to cause a convergence of
the rays: the aqueous from its convex form;
the crystalline by its double convexity and
greater density than the aqueous; and the
vitreous by a less density than the crystalline,
joined to its concave form.

The structure of the eye is in general adapted
to the reception of parallel rays; but, as the
distances of visible objects are various, so the
eye has powers of accommodating itself to rays
proceeding from different distances by altering
the distances of the crystalline from the retina,
which is done by the action of the ciliary
ligaments. We will now speak of the diseases
of this organ.

INFLAMMATION.

The conjunctiva is that membrane which
lines the eyelids, and covers the cornea and
the haw of the eye. Its inflammation is one
of the most common diseases to which this orb
is subject.

When inflammatory appearances have be-
come manifest in this part, the first thing to
be ascertained is, whether the transparent
cornea is affected or not. One sign is, that
the iris, at the border of the pupil, will not be
seen without difficulty. Attention must then
be directed to the other eye; and not finding
the pupils exactly alike as to size, &c., it may
safely be inferred that the smallest is in a state
disease; the sphincter muscle of the iris
having become contracted from sympathy.
The next thing to be observed is the blood-
vessels of the membrane under the eyelid. If
these appear turgid, and even if there is only
one of them shooting into the transparent
cornea, it is a diseased eye. Attention must
then be directed to the glandular bodies at the
upper edge of the iris; and if these are not
alike in colour, it may be predicted that the
horse will go blind from the effect of little
lymph being lodged there from previous inflam-
mation. The haw is likewise a criterion to go
by. If the haw is not the same in each eye,
but one protruding more than the other, the
indication is bad. These incipient appear-
ces of this disease are of great importance; for as
this disease is the one to which the horse is most
usually subject in the eye, it should be vigilantly
watched, as it frequently results in blindness.

This disease generally comes on in the night,
and is then thought of but little moment; the
groom supposing the eye to be injured by the
halter, or by rubbing it against the manger,
or some rough place in the stall; but this is
seldom the case; and, as to producing it by
blows, it is exceedingly difficult to wound the
eye. If, however, it should be occasioned by a
blow, there will be an abrasion on the external
surface; on examining which, it will be easy to
determine how to proceed. Take of
Extract of Saturn . . . 4 drachms (½ oz).
Spring water sufficient to fill a common-sized
wine-bottle.
Apply this lotion frequently every day. Or,
Take Sulphate of Zinc . . . . 1 oz.
Dissolve in the same quantity of water as
above. Either of these recipes, if the inflam-
mation arises from a blow, will effect a cure in
a few days.

This disease does not often attack aged ani-
mal, if they have not been previously affected
with it. They are most subject to it between
four and six years old, when their growth is
becoming nearly completed, and when, if
highly kept, a plethoric habit is produced; the
solids of the body ceasing to grow, and the
deposit of fat becoming greater than the sys-
tem requires. Young horses are, in early life,
but little susceptible to this disease. When
an attack commences, if nothing is done to
prevent it, the inflammation increases rapidly,
until the pupil is hid, and the whole surface
of the eye appears bloody. This, however, may
be wholly removed. The attack flies from eye to
eye; first beginning in one, then in the other
eye, probably at the interval of some months,
till one or both become blind. If one only
is lost, the general opinion is, that the other will
become perfectly sound, and be much stronger.
From these circumstances it would seem not
to be a local disease, but constitutional. It is
produced generally by living in a poisoned at-
mosphere. In cases where it has appeared, it
has been observed that the horses either do
not perspire at all, or perspire profusely, from
langur. The inflammation having its origin
in the conjunctiva, all the other parts partake
of it. The iris secretes pus, which falls into
the posterior chamber, where absorption takes
it up, or probably ulceration takes place.
Even the constitution appears to undergo a
DIAGRAM of the HORSE'S EYE.
change, when blindness ensues. This periodical ophthalmia generally ceases when one or both of the eyes go out, although, at first sight, one cannot tell how the constitution has been affected by the loss of this organ, or see a reason why the inflammation should not recur at intervals.

The disease may also arise from the effects of purging; but this only causes the constitutional tendency to the disease being brought into effect, producing debility from the medicine becoming the exciting cause. The disease then is constitutional, and requires effectual remedial measures to be adopted. Take of

Blue Pill. . . . . . . . . . 12 drachms.
Opium . . . . . . . . . . 2 dr.
Linseed Meal . . . . . . 1 oz.

Form into a mass with soft soap,
and divide into six balls. Give one every second morning fasting. Or, take of

Sulphate of Copper . . . . . 12 drachms.

Or, of

Sulphate of Iron . . . . . . 12 drachms.

Form either of these into a mass with linseed meal and soap, and divide into six balls, and give one every morning about eleven o’clock. These two last are strengthening, and when the disease arises from debility, will be found of essential service. Bleeding generally, according to the strength of the animal, should not be omitted, as it will relieve it in all its stages, though not eventually cure it. A good lotion may be composed of

Common Salt, a table-spoonful and a-half.
Spring Water, as much as will fill a wine-bottle.

Bathe the eyes several times in the day with this; or, take either of the lotions prescribed for blows in the eye.

The insertion of setons between the jaws have done good for a time; and considerable benefit has arisen from the following prescription—

Tartar Emetic . . . . . . . . 1 drachm.
Hog’s Lard . . . . . . . . . . 1 oz.

Form into an Ointment.
Rub a little on the side of the horse’s cheek, and also underneath the eye, until small pimples appear. Great care must be taken to prevent its going into the eyes.

For simple ophthalmia, local and general bleeding and physic are advised. Warm fo-

mentations should be at first used, and the following lotion applied six or eight times a day:

Cold Water . . . . . . . . . . 1 pint.
Tincture of Opium. . . . . . . 1 oz.

When the inflammation has abated, but a film is still left on the cornea, apply with a camel’s hair brush, twice a day, a few drops of the following:

Distilled Water . . . . . . . . . . 1 oz.
Nitrate of Silver . . . . . . . . . . 1 or 2 grains.

The horse should be kept in a cool and clean stable, where there are no offensive exhalations from manure.

Mr. Peall relates an experiment which he made on a horse affected with ophthalmia. “I have ordered him,” he says, “to be removed from the stable, where I observed he kept both eyes shut, into the open air, or to a very cool situation, and have watched the effects of the change. In the course of half-an-hour I have commonly found him begin to open his eyes gradually; and in the course of two or three hours, to keep them open boldly, and for a continuance, even though the situation he was placed in was not darkened or shady; for it cannot be denied that strong light is very prejudicial in such cases. Now to prove that the stimulus of the volatile alkali—the vapours of foul litter—was more offensive to the inflamed organ than that of light, I have placed the animal again in a hot stable, which did not admit much light, and, in the course of a few minutes, have observed him begin to close his eyes gradually, and, after an hour or two, to keep them constantly shut. Not satisfied, however, with this, I have removed the horse back again to a cool situation, and have observed the same effects to be produced as have been already detailed.”

Cataract.

The common termination of the foregoing disease is cataract; which is inflammation in the capsule of the lens with opacity. The opacity invariably begins in the centre, from its being the hardest, and having less of living power, so that the circulation becomes more easily affected. There being no simple cataract in the horse, many appearances of the lens take place when the eye is affected by the disease. In some, a general determination of
blood to the coats of the eye, when irritation ensues. The retractor muscle then acts from sympathy, which produces pressure on the tunica vitrea, and the cells of the vitreous humour are destroyed, together with the capsule of the lens. To prevent the lens floating about, lymph is thrown out, forming an artificial capsule. By this action of the retractor muscle, the aqueous humour is pressed upon by the lens through the other parts, and this humour against the transparent cornea. To prevent the eye from bursting, the humour becomes absorbed; the lens is thrown against the iris, which dilates, coming in contact with the transparent cornea; the pupil in consequence becomes lost. From these complicated effects, an operation is both difficult and useless. It has been performed several times at the Royal Veterinary College. But even if imperfect vision is restored, it is detrimental to the horse, causing him to shy, and rendering him unsteady and dangerous. When cataract occurs in the human subject, coughing is practised; but, in the horse, this is all but impracticable.

GUTTA SERENA, OR AMAUROSIS,

Is another disease of the eye of the horse, consisting of a paralysis of the optic nerve, which becomes insensible to the light, though admitted through a perfect organ. It is much more common in the human subject than in horses. Blistering behind the ears, on both sides, has been repeatedly tried for it, but without any success. Rowels between the jaws, kept open for a length of time, have also been tried, but without any satisfactory result.

On one occasion, a young veterinary surgeon, just emanated from the Royal Veterinary College, and who had not seen any practice previous to his going to that establishment, was called to a horse affected with inflammation of the eyes. He at once pronounced the necessity of taking blood; but being rather a timid operator, he, in striking the phleume, only just touched the jugular vein, the blood scarcely deigning to flow. Consequently he pinned up that side, and proceeded to the other, with no better success. The result was, that the horse’s neck became greatly swollen, and though it was well bathed, it had no effect. Suppuration took place, and the horse lost the vein on both sides: but while this was going on, the inflammation entirely left his eyes. The gentleman to whom he belonged kept him for two or three years after, but no inflammation ever returned.

Gutta Serena has followed an attack of stomach staggers, and, in many instances, has come on from excessive loss of blood after castration, and from ruptured liver. It has, also, appeared in a temporary form after apoplexy, and during gestation.

In treating for it, copious bleeding at the neck, followed by a dose of physic, is recommended. Local applications to the eye are of little service.

When the disease proceeds from the liver, stomach, or any other viscerum, bleeding is not always to be adopted, but should be regulated by the general health of the animal. When the above treatment fails, calomel, combined with opium, may be tried, and, in obstinate cases, strychnine.

CHAPTER XVI.

WOUNDS.—WOUNDS IN GENERAL; WOUNDS OF THE HEAD; CHEST; ABDOMEN; JOINTS; SHEATHS OF TENDONS; ARTERIES; VEINS; KNEES; GUN-SHOT WOUNDS; SUTURES.

WOUNDS IN GENERAL.

Wounds are a species of injury to which horses are not only perpetually liable, but they consist of so many different kinds, and require such various modes of treatment—according to the cause, appearance, situation,
WOUNDS. [MODERN VETERINARY PRACTICE.

depth, and state of the wound, or habit of the subject—that to discuss the whole of them with all possible or probable circumstances in which they appear, would be to write a volume on them alone. Even that space would, perhaps, not wholly be exhausted when we consider the simple and complex characters which they frequently assume, and the difficulties which, in numerous instances, are involved in their treatment. To enlarge, therefore, upon every probable means by which a wound may be received, is unnecessary; accordingly, we will exhibit their most prominent features, with the best means of their cure.

Wounds in general are subject to a great deal of variety, both in their nature and external appearance. The differences depend, in a very great measure, on the nature of the injured parts, the manner in which the wound has happened, and its extent.

Flesh wounds are, in appearance, nature, and degrees of danger, quite different from those of the tendons. There is also an essential difference between such as are made with a sharp-cutting instrument, and others, in which the fibres, besides being divided, have suffered considerable contusion and laceration. A wound made with a narrow-pointed instrument, is also of a very different nature from one that has an ample orifice.

The degrees of danger attending every wound, depend very much on some of the following circumstances:—

The extent of the injury; the more or less violence which the fibres of the part have suffered, besides their division; the nature of the blood-vessels, or nerves, which happen to be cut; the nature of the wounded part, in respect to its general power of healing favourably or not; whether the operations of the system at large, and life itself, can be well supported or not, while the functions of the wounded part are disturbed, interrupted, or suspended by the accident; the age of the patient, the goodness or badness of his constitution, and the opportunities which there may be of receiving proper aid and assistance of every kind.

As a general observation, we may state, that a wound that is made with a sharp-cutting instrument, and which takes the character of a mere incision, is attended with less hazard than any other kind of wound whatever. The fibres have only simply been divided. They have suffered no contusion, nor laceration; and are, consequently, less likely to inflame, suppurate, or slough, and likely to admit of being united again in a very expeditious manner.

Lacerated wounds, are those in which the fibres, instead of being divided by a cutting instrument, have been torn asunder by some violence, capable of overcoming their force of adhesion. The edges of such wounds, instead of being straight and regular, are jagged and unequal.

Contused wounds is a term applied to such as are occasioned by some blunt instrument, or surface, which has violently struck a part of the body.

Lacerated and contused wounds differ from simple incised wounds, in appearing, at first view, much less alarming than the latter, while in reality they are much more dangerous. In simple cut wounds, the retraction of the parts, and the bleeding, are generally much more considerable than in a lacerated wound of the same size. Notwithstanding these circumstances, however, they commonly admit of being healed with far greater ease. Indeed, lacerated and contused wounds are scarcely ever attended with any serious effusion of blood, even though some large blood-vessels may be injured. In judging of the severity of these, this is apt to lead some persons, even practitioners, astray; for, in proportion as there is little bleeding, it may with safety be concluded that serious violence has been done to the fibres and blood-vessels.

A punctured wound is one that is made with a narrow-pointed instrument, and has its external orifice small and contracted, instead of being of a size proportionate to its depth. A wound produced by the thrust of a sword or bayonet is an example of a punctured wound.

Wounds of this description are in general infinitely more dangerous than incised ones, notwithstanding the latter have the appearance of being by far the most extensive. The degree of danger, in cases of punctured wounds, always depends on the additional injury, and rough violence, which the fibres have suffered, besides being divided.

Some of the disagreeable consequences of
such wounds are also imputed to the frequent
great depth to which they are liable to extend.
In consequence of this, important parts and
organs are often injured. Such cases are less
easily cured, owing to the difficulty of ex-
tracting any extraneous substances which may
happen to be lodged in the wound. All punct-
tured wounds and stabs are at the same time
dangerous, inasmuch as they are particularly
apt to be followed by a considerable amount
of inflammation, fevers, deep-seated abscesses,
sinuses, &c.

Wounds of this description are, in this
country, not very common. The stings and
bites of certain insects, and the bites of vipers,
mad dogs, cats, &c., are the only instances
which we meet with. The only insects to be
dreaded are the stings of the wasp, or the
hornet. This insect, to appearance, is the
most formidable creature of the winged tribe
in Britain, the sting being frequently attended
with the most acute pain and inflammation.
Even the sting of the wasp, should it occur
where the skin is thin, such as on the inside
of the thigh, occasions extreme pain and
irritation.

WOUNDS OF THE HEAD.

Wounds of the head of the horse do not so
frequently occur as might be expected. The
principal occur on the ears, the eyelids, the
nose, or the salivary gland or duct. This duct
is situated at the angle of the jaw, where the
pulse of the animal is felt. It is sometimes
liable to be torn, when the saliva escapes by it,
instead of passing on to the mouth to mix
with the animal’s food. It also frequently
occasions great debility.

From the situation of the parotid duct, and
its liability to become wounded, what is called
a salivary fistula may be the consequence,
unless steps are immediately taken to afford
relief. The cheek and face become considerably
swollen; to prevent the increase of which, the
actual cautery should be used. A budding-
iron, however, is the best instrument; after
using which, draw the lips of the wound
together with a suture, and apply adhesive
plaister over the whole, in strips, about a
quarter of an inch apart, first cutting the hair
close off all round the part, that the plaister
may adhere more firmly.

Lacerations of the horse’s ear sometimes
occur. In such cases have him cast, and the
lacerated part cut off. After this operation,
if it should not look at all pleasant, remove as
much more as will make it do so; then crop
the other ear to correspond. This is the only
method that can be pursued, as, from the little
vascularity of the ear, it being principally
composed of gristle, union cannot be expected
to take place.

The eyelids frequently become lacerated,
and very much torn, from nails or splinters of
wood about the rack, manger, or standing.
In this case, a small curved needle, with
whity-brown thread, should be taken, and
sutures introduced in such a manner as to
bring the parts as much in contact and as
near to the appearance they had before the
accident took place. After this, use the fol-
lowing:—

<table>
<thead>
<tr>
<th>Substance</th>
<th>Measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sulphate of Zinc</td>
<td>1/2 oz.</td>
</tr>
<tr>
<td>Spirit of Wine</td>
<td>2 do.</td>
</tr>
<tr>
<td>Water</td>
<td>16 do.</td>
</tr>
</tbody>
</table>

Apply this lotion to the parts affected three
or four times a day.

Wounds of the nose, or nostril, sometimes
occur, and are exceedingly difficult to heal, in
consequence of our not always being able to
apply proper remedies. The only thing to be
done is to sew up the lacerated parts, and
apply compound tincture of myrrh, as in a
common wound. It is difficult, in such cases,
to recommend another distinct mode of treat-
ment without the real nature of the wound is
perfectly ascertained.

WOUNDS OF THE CHEST.

These wounds occur mostly in large towns,
where there is considerable movement with all
kinds of vehicles; when the shaft of one car-
riage comes in contact with the horse of the
one he may chance to meet, enters his chest,
and often causes immediate death to the horse.
In such cases the first thing to be ascertained
is the depth of the wound; and, in order to
restrain the rapid action of the circulation,
copious bleeding must be used. A piece of
tow, well smeared with digestive ointment,
should be introduced into the wound, in order
to procure a discharge as soon as possible.
The horse should be kept without food for at
least twelve hours; at the expiration of which,
a ball, composed of the following ingredients, should be given:—

Aloes . . . . . . . . . . . . . . . . . 4 drachms.
Resin . . . . . . . . . . . . . . . . . 2 do.

Form with soft soap and linseed meal.

If, by this time, the parts should have become much swollen, bathe them well with hot water; and if the discharge is once produced, it is a sign that the animal is going on well. Continue the dressing, with the medicine occasionally, and a cure will soon be effected. Should the wound, however, not have been made in the direction before named, but have entered the cavity of the chest, and the lungs become in any means ruptured, the case is then hopeless. This will easily be ascertained by air rushing out of the wound, and by the peculiar scarlet hue of the blood.

If swelling should take place between the legs, or under the chest, take the phleme and strike it, to let out the air which has been extravasated.

WOUNDS OF THE ABDOMEN.

Wounds of the abdomen generally arise from the horse having been gored with the horns of some mischievous bull or cow, whilst in the field, or by his having been staked, or not unfrequently by some of the hooks carelessly attached to the harness. These have sometimes been the cause of frightful lacerations, when lock-jaw has been known to supervene.

When they are so severe as to penetrate the cavity of the abdomen, they are attended with much danger. If any of the intestines should protrude, they should be carefully replaced, unless they should be very cold, or mortification appear; in which case the parts should be well bathed with warm water, not too hot at first, but made warmer by degrees, until it approaches to blood-heat; then, after returning the intestines, sew up the external wound, and apply a roller, padded, to the part. Neither food nor water should be given, but clysters of gruel, and also gruel as a draught; but this sparingly at first. When the roller is to be removed it should be done with the greatest caution; and if appearances are favourable, a pleget of tow, and a large adhesive plaister over the whole; then the padding and the roller should be applied as before. In such cases copious bleeding should be used, as soon as the first dressing is over. If mortification should have taken place, the horse will soon evince it; but, should better fortune attend the treatment, he must be brought on by degrees, and not be fed too freely for some time.

WOUNDS OF JOINTS.

From the tendinous and membranous nature of the parts which surround the large joints, wounds in them, whether of a punctured or incised kind, are attended with great danger; and, although these joints are not very sensitive in a sound state, yet, when inflamed they become exceedingly so, and frequently are the cause of violent pain and fever.

Superficial wounds of the joints are often disagreeable cases; but the danger is always increased when the injury penetrates the capsular ligament. When this is the case, it may be detected by the introduction of a probe, and frequently by a discharge of the synovia, which is secreted by the inner membrane of the capsular ligament of the joint, for the purpose of facilitating its motion. But as a discharge of a similar kind may proceed from mere wounds of such (bursæ mucosa) synovial bags, as in the case of windgalls, &c., that lie under the tendons of muscles, in the vicinity of joints, we might be deceived, were we not acquainted with the situation of these little membranous bags. Wounds which penetrate large joints, must be held as much more dangerous than those in which only these bursæ are opened.

Almost all the joints of the horse are liable to be laid open, and their cavities exposed. The stifle, the pastern, and the knee, have been seen all at once, completely exposed; but the knee-joint is, of all others, the most frequently liable to accident. It does sometimes occur to the shoulder-joint, but very rarely. When a joint is penetrated, there is an escape of synovia, or, as it is commonly called, joint-oil. In consequence of the escape of this fluid, the ends of the bones are brought together, occasioning, in conjunction with the air getting in, considerable inflammation through the whole extent of the capsular surface, and causing that exquisitely tender sensation which the horse feels on having the joint touched. In some cases the fever runs so high as to prove fatal. An instance of this occurred at the Royal
Veterinary College. A large cart-horse was brought in with an open joint. Ultimately the opening closed, but new granulations formed, and a wound about the size of half-a-crown was the consequence. This wound was ordered to be dressed with spirits of turpentine, which was accordingly done; but, from symptomatic fever, the animal died in three or four days. When a joint is early discovered, after being penetrated, the synovia will flow white and pure, or it may have a little tinge of blood in it; but, if the accident is not discovered for three or four days, the joint-oil will be found to put on a yellowish colour, and the discharge be considerably increased. If means are not speedily taken to close the external opening, coagulable lymph is thrown out; and in consequence of the inflammation being great, the vessels may insulate together, and in all probability a stiff joint will supervene. In some cases, the pain and irritation are so great, that the animal either sinks under it, or becomes a mere skeleton. But this need not be considered a matter of surprise, when we reflect on the treatment of the old farriers, who, in general, made use of strong stimulants, taken from their long list of infallible nostrums.

The treatment of open joints, if discovered in their recent state, may not be so difficult. The first object to which attention should be directed is to remove all extraneous matter, such as dirt, gravel, and any other substance that may aggravate the affected part. Then proceed to close the wound, which must be first commenced by clipping off the hair for some distance all round it. If not large, strips of adhesive plaister should be applied, drawing the lips of the wound as closely as possible together, and placing over them a plaet of tow, and immediately after a linen bandage, about three yards long, and four inches wide, so that the shutting-up of the cavity may be complete. In addition to this, the symptoms of irritation, both local and general, must not be neglected; for if the symptomatic fever is high, the case must be treated accordingly. This will be discovered by the animal having lost his appetite, the heat and dryness of his mouth, as well as the quickness and weakness of his pulse, and his breathing short. If these are the symptoms—which in all probability will occur—immediately take from two to four quarts of blood, and give the following ball:

No. 1.

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cape Aloes</td>
<td>1 drachm</td>
</tr>
<tr>
<td>Digitalis</td>
<td>2 do.</td>
</tr>
<tr>
<td>Linseed Meal</td>
<td>3 do.</td>
</tr>
</tbody>
</table>

Form with soap.

Give a ball of this kind night and morning, until the fever and irritation are abated. Or,

No. 2.

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cape Aloes</td>
<td>1 drachm</td>
</tr>
<tr>
<td>White Hellebore</td>
<td>1½ do.</td>
</tr>
<tr>
<td>Linseed Meal</td>
<td>3 do.</td>
</tr>
</tbody>
</table>

Form into a ball, and give as the first. By this means the irritation will be allayed, the fever abate, and the beating of the pulse become less rapid.

When the wound is more extensive, or more irregular, sutures should be employed with the plaet of tow, as before described. The part should be well bandaged, and every means taken to keep the horse as still as possible. Use a neck-cradle, lest, from the irritation, he may be inclined to gnaw the part affected. If these appliances have not the desired effect, recourse must be had to the actual cautery; and, if the opening is not too large, the budding-iron, of as good a shape as can be used, must be brought into operation, and the edges lightly touched with it. If the wound should be large and irregular, use a firing-iron carefully. These means have succeeded when all others have failed. Let the iron be heated to a dull red heat, which will be quite sufficient; and care must be taken not to inaninate it too far, otherwise considerable inflammation may follow. A stoppage of the synovia will show when the cautery has been sufficiently applied, when a plaet of tow must be put over it, and a poultice of bran, wetted frequently with the following:

Sal-ammoniac, powdered     4 oz.
Sugar of Lead               1 do.
Vinegar                     3 pints.
Water                       1 do.

If the oozing of the synovia recommences, apply the iron again; and, as often as the oozing appears, repeat it, by which success may eventually be calculated on. In some aggravated cases blisters have been immediately applied with good effect. Rowels are sometimes employed as near the part as convenient,
but there is little faith to be put in them. Give bran mashes, or half bran and oats made damp; if there is much difficulty in administering the fever-balls, give of

- Chamber Salts . . . . . . 4 oz.
- Linseed Meal . . . . . . 2 do.
- Hot Water . . . . . . . . 1 quart.

Mix well together for a drink, and repeat it morning and night. In mixing the meal with the above, do so first in a basin with a little cold water, to prevent its clotting together.

WOUNDS OF THE SHEATHS OF TENDONS.

This sort of wounds frequently occur both in the hind and fore legs, during hunting, staking, and the stubbing-in of coppices. They are also sometimes produced by the stable-fork, and are often attended with considerable pain. Their treatment differs in no respect whatever from that laid down in the description of wounds of the joints.

WOUNDS OF THE ARTERIES.

Every one who pretends to deal with the wounds of a horse, should have an intimate knowledge of the course of the arteries, so that in performing operations he may avoid wounding them. For stopping the flow of blood there are several methods; and unless they are performed with perfect coolness, they are apt to be done in such a manner as may be the cause of proving fatal to the patient. How necessary, therefore, is it that every practitioner should have a thorough acquaintance with the arterial system. Bleeding from arteries is stopped generally by compression and astringents, by ligatures, by the actual and potential cautery; sometimes by styptics; and not unfrequently, if the artery be only wounded, by dividing it altogether.

It must be plain to every one who understands the course of the circulation, that pressure made on that part of a wounded artery which adjoins the wound nearest the heart, must check the effusion of blood. The current of blood in the veins, running in the opposite direction, requires the pressure to be applied to that side of the wound which is most remote from the heart; and as pressure is the best means of impeding haemorrhage, so is it the most effectual. The ligature, the application of a roller and compressors, only become useful in the suppression of haemorrhage on the principle of pressure; the cautery-caustics and styptics are otherwise applied.

The different things that have been praised as infallible, in their application to wounded arteries, would seldom or ever have succeeded without compression. This was always requisite, even in the use of caustics, which were bound on with sufficient tightness to resist the impulse of the blood in the artery and the premature separation of the eschar, occasioned by the actual or potential cautery.

When the blood does not issue from any particular vessel, but from numerous small ones, compression is preferable to the ligature. The employment of the latter renders it necessary to tie the whole surface of the wound. The sides of the wound should be brought accurately together, compressors placed over the part, and a roller applied with sufficient tightness to make effectual pressure, but not so forcibly as to produce a danger of the circulation being completely stopped. If compression can ever safely be trusted in bleedings from large arteries, it is when these vessels lie immediately over a bone, against which they can be advantageously compressed.

The ligature, being well known to be a safe and easy means of stopping haemorrhage, is attended with much less pain than former methods. It may, indeed, be set down as a rule, that where large arteries are wounded, no styptic application whatever should be trusted; but immediate recourse should be had to the ligature, as being, when properly applied, the most simple and safe of all methods. In explaining the action of the ligature, when applied round an artery, without including the surrounding parts, we have found the internal coat of the vessel is torn through by it. If the ligature is tied round with sufficient tightness, it will cut through the inner and middle coats; and although it is immediately removed, the vessels always become permanently impervious at the part which was tied as far as the first collateral branches, above and below the obstructed parts. This division of the internal and middle coats of the artery, produces an obstruction to the circulation of blood through its canal.
There must be a small quantity of stagnant blood, just within the extremity of the artery; but this does not, in every instance, immediately form a coagulum capable of filling up the canal of the artery. In most cases, only a slender coagulum is formed at first, which gradually becomes larger by successive additions. This coagulum is always at first of a tapering form, with its base at the extremity of the artery. But its formation is not material; for, soon after the ligature has been applied, the end of the artery inflammes, and the wounded internal surface of its canal being kept in close contact by the ligature, adheres, and converts this portion of the artery into an impervious, and, at first, conical sac. It is to the effused lymph, that the base of the coagulum adheres, when found to be adherent. Lymph is also effused between the coats of the artery, and among the parts surrounding its extremity. In a little time the ligature makes the part, on which it is directly applied, ulcerate, and, acting as a tent, a small aperture is formed in the layer of lymph effused over the artery. Through this aperture, as long as the ligature remains, a small quantity of pus is discharged; and finally, the ligature itself escapes, and the little cavity, which it has occasioned, granulates, and fills up. The external wound then heals, leaving the cellular substance, a little beyond the end of the artery, somewhat thickened and indurated; but, if it should be in a situation where a bandage can be applied, it ultimately becomes absorbed.

As all styptics are not to be depended on, the judicious practitioner will seldom apply them, as they generally tend to irritate, and rarely do good. They are sometimes, however, proper to be applied to diseased surfaces, where the vessels seem to have lost their natural power, or disposition to contract or draw themselves together again.

Firing, or the actual cauterity, is an excellent styptic to stop the bleeding of an artery, as in docking, castration, &c. It is generally resorted to as the safest styptic in operations of festulous withers, and in dissecting out fungus flesh, where there is a number of small arteries which are apt to be wounded. The actual cauterity is the only means that here can be employed with any good effect. In these cases the horse's body should be kept open with alterative medicines; such as the following:—

Cape Aloe . . . . . . . . 2 drachms.
Sulphur . . . . . . . . . 3 do.
Form into a ball with soft soap.
Give one occasionally, and feed with half bran and half oats made damp.

WOUNDS OF THE VEINS.

Wounds of the veins are generally produced by incautiousness in blood-letting; and although this operation is performed by some of the greatest bunglers that possibly could take a phleme and blood-stick in hand, yet it is frequently so dexterously done, that no evil effects spring from it. Still, it does happen even with the most experienced practitioner, either from inattention in pinning up the orifice, drawing the skin a considerable way out, or not adjusting the lip of the wound equally together, that blood becomes extravasated into the surrounding cellular membrane. This, however, may sometimes arise from the foul constitution of the horse, when every little scratch or wound has a tendency to inflame and suppurate. Where this is the case, apply the following:—

Sal-ammoniac . . . . . . . . 1 oz.
Extract of Saturn . . . . . ½ do.
Vinegar . . . . . . . . . 1 pint.
Water . . . . . . . . . 1 do.

Shake these well together in a bottle, and apply frequently during the day. If absorption takes place, and the parts regain their former appearance, all is well; but if the tumour suppurates, and on pressing the part a fluctuation is felt, a depending opening should be made, or a seton introduced through it. If inflammation should rise from the vein itself, it must spring from the use of rusty or unclean phleumes; but the probability is, that it has been punctured through, in consequence of driving the phleme with too great violence in the act of bleeding. It also sometimes arises from the horse being suffered to have his head at liberty immediately after bleeding, instead of being tied up for at least two or three hours; the pin causing irritation, the horse is inclined to rub against anything that is in his way, such as the edge of the manger, &c. Sometimes this morbid action arises from the constitution. When this is the case, it begins
to make its appearance in about two or three days after the operation of blood-letting, by a small tumour at the situation of the orifice, the lips of which unclose and look red, with a sort of ichorous discharge, sometimes accompanied with blood. In this case, if the progress is not stopped, the tunnelfaction extends along the course of the vein towards the head; the vessel becomes hard, and the blood contained in the trunk, forms into a firm conglom, by which it becomes impervious, and all attempts to save it afterwards prove a failure. Suppression of the tumour now begins to makes its appearance; but this is not always the case in the immediate part where the original puncture took place; abscesses will form in various situations above. If not taken in time, the morbid action will extend upwards so as to involve the side of the head as well as the neck in the disease; and when this occurs, it greatly interferes with the horse's eating and drinking. In such instances symptomatic fever is apt to run high, and, from the excess of irritability brought on, the animal frequently becomes a victim.

The treatment for inflammation of this sort is altogether difficult, and frequently doubtful. It has been by some writers thought, that in the early stage of the disease, the better plan is to close the venial orifice, which is to be done by the use of the budding-iron, applied to its outer edge. But this, by others, has not been approved; for if sloughing of the part is caused, it will not remove the main disease. It may, however, have a tendency to heal the orifice without having any connexion with the vein, where the disease may be going on all the time, to a very considerable extent. It is also said, that the ichorous oozing once being stopped, the vein will become in all respects as it was at first. This, however, has been either questioned, or wholly denied; for if the vein once takes on inflammation, its obliteration is certain to follow. Nor is this of so much danger as many persons would have us believe. Still, in such cases, the head of the horse should be kept tied up, so that he may have as little motion as possible.

The treatment adopted in such cases, and pursued with most success, has been, instead of using the cautery, to heal up the original wound—to keep that wound open, then intro-

duce a probe as far as possible, up the course of the vein towards the head. When this has been done, the operator should feel down upon the end of the probe with his finger, cut down on the course of the vein about an inch above the end of the probe, and apply a ligature firmly. The probe-pointed bistoury should then be taken, and a slit made up the length of the vein, which may be obliterated. Let this wound be well washed with warm water, and a suture or two applied, and a piece of tow or tape dressed with digestive ointment, until suppuration takes place. After this, in all probability, the sutures will come away, when dressing as for a common wound, with compound tincture of myrrh, should be begun. If abscesses or sinuses have become formed, the best method of treatment to be adopted is to introduce setons, so that the matter formed may escape by a depending orifice. Sometimes these sinuses assume an indolent manner, and become very troublesome. Where this happens, inject them with a solution of sulphate of zinc, which will generally be found sufficiently strong to answer all purposes. For this injection take of

<table>
<thead>
<tr>
<th>Substance</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sulphate of Zinc</td>
<td>1 oz.</td>
</tr>
<tr>
<td>Water</td>
<td>4 dr.</td>
</tr>
</tbody>
</table>

Let the water be warm, and dissolve the sulphate of zinc in it. This injected into the sinuses will be found of great service, and less irritable than corrosive sublimate, copperas, &c.

During the application of the foregoing remedies, give the following:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blue Pill</td>
<td>8 dr.</td>
</tr>
<tr>
<td>Cape Aloes</td>
<td>8 dr.</td>
</tr>
<tr>
<td>Resin</td>
<td>8 dr.</td>
</tr>
</tbody>
</table>

Form into a mass with linseed meal and soft soap.

Divide into six balls, and give one every second morning, first thing on going to stable.

It sometimes happens that the plate and thigh vein becomes inflamed, in consequence of the phleme being driven in too far, and puncturing the facia and parts underneath the vein. Should this be the case, the best application is, to bathe well with hot water five or six times a day, and make up a ball of the following ingredients:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cape Aloes</td>
<td>4 dr.</td>
</tr>
<tr>
<td>Resin</td>
<td>2 dr.</td>
</tr>
</tbody>
</table>

Form with soft soap, and give one every second day.
WOUNDS.] THE HORSE, AND [WOUNDS.

BROKEN KNEES.

Horses, in the act of falling, endeavour, as much as possible, to save their head from coming in contact with the ground; but if not able in time to put forth their fore leg to do this, the knees generally become the sufferers, and, in some cases, to a very considerable extent. In such accidents, great laceration, open joint, and, at least, shaving, as it were, the hair completely off the knee to a greater or less extent generally occur.

Should the cavity of the knee be opened, and joint oil escape, sufficient instructions as to the proper method of treatment to be adopted, have been given in the article Wounds of the Joints, to which we beg to refer. But when the laceration only extends to the skin, there is only one safe, and, we should say, proper mode of treatment. In the first place, all irritating applications are to be avoided; and, instead of them, the knee and surrounding parts should be well bathed with hot water for at least half-an-hour. A poultice, composed of linseed meal and warm water, should then be applied, and continued until the inflammation is subdued. After this, apply the following:—

Extract of Saturn . . . . 2 drachms.
Tincture of Myrrh, compound . 2 oz.
Water . . . . . . . . . . . 3 do.

Apply this to the wounded knees, until they are skinned over; then put on a mild blister, which will prevent, in many bad cases, even the appearance of a scar, if well managed.

This being accomplished, the next thing is to promote the growth of the hair. Many recipes are given to make the hair grow, but most of them are useless; for nothing acts specifically in this way. Whatever gently stimulates the skin being the most proper for this purpose, use every day a little of the digestive ointment, which is an article no stable ought to be without; or use the following, especially if the knees are black:—

Digestive Ointment . . . . 1 oz.
Gunpowder, rubbed fine . . . 1 drachm.

Mix, and rub the part with some of it daily.

GUN-SHOT WOUNDS.

Gun-shot wounds are made by hard bodies violently projected from cannons, muskets, and other fire-arms. Those from the rifle, however, occasion by far the greater number. They are the most considerable of the confused kind of wounds; and what is to be said of them, will apply, more or less, to all confused wounds, according to kind and degree. Daily observation shows that balls which obliquely strike a surface, do not penetrate it, but are reflected, although they may be impelled with the greatest force, and although the body struck may be as soft and yielding as water. This alteration in the course of the ball, not only occasionally happens on touching the surface of a body, but also sometimes after it has penetrated its substance. A bone or a tendon may change the direction of a ball, if it touches them obliquely. Hence it is manifest how it happens that the track of a gun-shot wound is not always straight, and how the balls sometimes run under the integument for a considerable distance, both in the body and the limbs.

A ball, when it strikes a part of the body, may cause four kinds of injury. First, it may only occasion a contusion, without penetrating the part, on account of its being too much spent, or on account of the oblique way in which it has struck the surface of the body. Secondly, it may enter and lodge immediately under the surface of a part, in which case, the track of the wound has only one aperture. Thirdly, it may pierce through and through; and then there are two openings, one at the entrance, and the other at the exit of the ball. In such cases, the circumference of the aperture, where the shot has entered, is usually depressed; that of the opening whence it escaped is elevated. At the entrance, there is commonly more contusion than at the exit of the ball; and the former is generally narrower; the latter wider, and more irregular, especially when the round smooth figure of the ball has been changed by its having struck a bone. Fourthly, a cannon-ball may tear off a whole limb.

Gun-shot wounds differ very much, according to the kind of body projected, its velocity, and the nature and peculiarities of the parts struck by it. The projected bodies are mostly bullets, sometimes cannon-balls. From the contusion which the parts suffer on the violent passage of the ball through them, there is most com-
WOUNDS

Secondly, for, things can be detached, which is afterwards thrown off in the form of slough, and which prevents such wounds from healing so readily at first, and makes most of them suppurate. This does not take place equally in every gun-shot wound, nor in every part of the same wound; and the difference commonly arises from the variety in the velocity of the body projected; for, where the ball has passed with little velocity, which is sometimes the case at its entrance, but still more frequently at the part last wounded, the injury may often be healed by the first intention.

Foreign bodies are more frequently met with in gun-shot wounds than any others, and are commonly of three kinds. First, pieces of clothing, leather, part of a girth, or other things which the ball may have forced before it. Secondly, the ball itself. Thirdly, loose splinters of bone. It is only when the ball strikes a naked part, does not touch a bone, but goes through and through, that the wound can be free from extraneous matter. Foreign bodies are the cause of numerous unfavourable symptoms, by irritating sensitive parts, and exciting pain, inflammation, haemorrhage, and long suppurations. They are more productive of such evils, the more uneven, pointed, and hard they are. Hence spiculae of bone are always most to be dreaded.

When a ball strikes a bone, the concussion produced is another occasion of bad symptoms to be added to those already mentioned. When slight, its effects are confined to the part injured. Sometimes they extend to the neighbouring joints, in which they produce considerable inflammation, frequently abscesses, and, in many cases, stiff joint, rendering the animal ever afterwards useless.

From the circumstance of the inner surface of gun-shot wounds being more or less deadened, they are late in inflaming. But when a ball has fractured a bone, and caused great injury to the softer parts, independently of what has been caused immediately by the ball itself, the inflammation will probably rapidly come on, because the deadened parts will bear no proportion to the laceration, or wound in general.

When the ball moves with little velocity, the mischief is generally less; the bones are not so likely to be fractured, and the parts are less deadened. However, when the velocity is just enough to splinter a bone which is touched, the splintering is generally more extensive than if the impetus of the ball had been much greater, which would rather have taken a piece out. When the ball moves slowly, it is more likely to be turned by any resistance it may encounter in its passage through parts; and hence the wound is more likely to take a winding course. When a ball enters a part with great velocity, but is almost spent when it comes out again, in consequence of the resistance it has met with, there may be a great deal of sloughing about the entrance of the wound, and little or none about the exit, owing to the different degrees of celerity with which the projectile has traversed the parts.

As the ends of the torn vessels are contused and compressed, gun-shot wounds have little tendency to bleed much; and unless very considerable vessels are lacerated, they do not bleed at all: sometimes not in this case. The greatest danger of bleeding is always when the dead parts are detached eight or ten days after the injury. Angular, uneven bodies, such as pieces of iron, cut lead, &c., always occasion far more dangerous wounds than round even bodies, like leaden bullets. Wounds occasioned by small, are frequently more perilous than others produced by larger balls, because their track is so narrow that it cannot be traced, nor the extraneous body itself so easily extracted. Such a shot oftentimes injures a visceræ, when there is not the smallest external symptom of this being the case. Sometimes a great part of the danger arises from the number of shots which have entered.

In treating for gun-shot wounds, the first thing to be done is to ascertain, if possible, their extent; which is, at all times, best done with the finger, in preference to a probe. Besides, in extracting the ball, or any foreign piece of matter, which ought always, at once, to be extracted, the finger will act as a director. If extraneous substances remaining in the wound, either loose gradually, and come into view, they may be easily removed; but if they be easily removable, or continue concealed, they may prevent the cure, and frequently give birth to a fistulous ulcer. In

215
some instances foreign bodies remain in during life, without inconvenience; and, in other cases, after a time they bring on a renewal of inflammation and suppuration. Sometimes a foreign body changes its situation, and afterwards makes its appearance at a part altogether away from its original seat, where it may excite inflammation and suppuration.

When the ball lodges in the wound, it is often difficult to trace it, as the parts collapse after its passage; and as it does not regularly take a straight direction through the injured part, but oftentimes a very tortuous one, which is more apt to occur as the ball is more spent. In every case in which it is not easily discoverable, all painful examinations should be abandoned, and the foreign body left in its situation, where it rarely creates any trouble.

Sometimes the ball may be both easily found and extracted. If the integuments under which it is lodged, should be so confused that they will probably slough, they are to be considered as already dead; and an opening is to be made in them for the extraction of the ball. But when the ball lies so remotely from the skin that it can only just be felt, and the skin itself is quite uninjured, no counter-opening ought to be made. The wound will heal better with the ball left in, and far less inflammation take place in the vicinity of this extraneous body, than about the orifice of the wound. A counter-opening always renders the inflammation at the bottom of the wound as great as at its orifice. It is better to let the wound heal up, and extract the ball afterwards.

As a certain portion of the parts surrounding the orifice made by the ball, becomes bruised, sloughing must be expected, as it is the operation of separating the bruised or dead bodies from the living. In some cases this takes a little time, when it should be hastened on, by applications such as the following:

\[
\begin{align*}
\text{Oil of Turpentine} & \quad 3 \text{ oz.} \\
\text{Olive Oil} & \quad 3 \text{ do.}
\end{align*}
\]

Shake well together in a bottle, and rub some on, for a distance of six inches all round the wound. This will stimulate it to put on the suppurative process. Apply a tent in the wound, smeared over with the common digestive ointment. When the suppurative process appears too great, desist from applying the liniment, and use, instead, the following lotion:

\[
\begin{align*}
\text{Alum} & \quad 1 \text{ oz.} \\
\text{ Sulphate of Zinc} & \quad 2 \text{ drachms.} \\
\text{ Water} & \quad 1 \text{ pint.}
\end{align*}
\]

Dissolve the alum and zinc in the water.

Apply this two or three times in the day. The horse should be supported well; for, in general, these cases come at a time when provender is short, as in time of warfare, &c. Bleeding in gun-shot wounds is not to be recommended, unless symptomatic fever should run high; and even then it should be done with caution; for it frequently happens, when the sloughing takes place, the wound bleeds rather more than is to be desired. In such cases use an astringent lotion. As before stated, keep the horse well, or disappointment in all the treatment may in a great measure be the result. Give the following every morning:

\[
\begin{align*}
\text{Sulphate of Iron} & \quad 10 \text{ drachms.} \\
\text{Ginger} & \quad 12 \text{ do.} \\
\text{Gentian} & \quad 12 \text{ do.} \\
\text{Linseed Meal} & \quad 6 \text{ do.}
\end{align*}
\]

Form into a mass with soft soap.

**Sutures.**

In the treatment of wounds, sutures have been frequently mentioned. It may therefore not be improper to name those principally in use, and the method of applying them.

A suture, in surgery, means a mode of uniting the edges of a wound, by keeping them in contact with stitches.

*The Interrupted Suture.*—The wound being cleansed of all clots of blood, and its lips brought evenly into contact, a curved needle, armed with a ligature of thread doubled, or good twine, is to be taken, and carefully passed from without, inwards to the bottom, and so on from within outwards. Care must be taken to make the puncture far enough from the edge of the wound, lest the ligature should tear quite through the skin and flesh. The other stitches are only repetitions of the same process. The threads having been all passed, generally begin to tie them in the middle of the wound; though if the lips of the part be carefully held together by an assistant, it will not be of great consequence which stitch is tied first. The
common rule is, that one suture is sufficient for every inch of the wound; but in some instances a stitch must be more frequently made than this, particularly when a wound gapes very much, in consequence of a transverse division of muscles. It is necessary to pierce the skin at a sufficient distance from the sides of the wound, lest the thread should cut through the flesh in a short time; the distance should be about three or four-tenths of an inch. When a wound is very deep, it would be wrong, and even, in many instances, dangerous to drive the needle through a vast thickness of parts. Other wounds, of considerable length, might not be in some places four-tenths of an inch deep, though it is true, sutures—the interrupted one at least—can never be requisite at such points.

The interrupted suture obviously receives its name from the interspaces between the stitches; and it is the one most frequently employed. Its action is always to be assisted and supported, either by a bandage, if the wound is in the limbs. If in other situations, by adhesive plaster, &c.

The Glover's Suture. This had also the name of the continued suture. It was executed by introducing the needle first into one lip of the wound from within outwards, then into the other the same way, and in this manner the whole track of the wound was sewed up. But the Glover's suture is now almost fallen into desuetude, as improper to be employed in cases of common wounds. When it is remembered in making this suture, how many stitches are unavoidable, how unevenly they are made, and in what a pucker state the suture drags the edges of the skin together, and what irritation it produces, we can no longer be surprised at its now being never practised.

The Twisted Suture is not very applicable to the horse, though by some writers it is recommended for certain wounds, as the eyelids, lips, nostrils, &c. It may be advantageous in some cases, but the interrupted has been preferred to all others, and on all occasions.

CHAPTER XVII.

ULCERS.—ULCERS IN GENERAL; FOLL-EVIL; FISTULOUS WITHERS; ULCERS IN THE MOUTH; STRANGLES; VINES.

ULCERS IN GENERAL.

Ulceration is the result of a certain process which sores sometimes undergo in animal bodies. In this process the lymphatics appear to be, at least, as active as the blood-vessels. An ulcer may be defined as a chasm formed on the surface of the body by the action of the absorbents in removing parts back into the system. Or, in other words, it consists of the absorption or removal of substance. It is a useful process of nature, though very usually a troublesome disease. At first, it may be difficult to conceive how a part of the body can be removed by itself; but there is not more difficulty in conceiving this, than how a body can form itself. Both facts are equally well confirmed. When it becomes necessary that some whole living part should be removed, nature effects the object by conferring a new activity on the absorbents, and by throwing the part to be absorbed into a state which yields to this operation. The absorption of whole parts in disease, arises from several causes, but those we have principally to contend with, either arise from the parts becoming bruised, or from constitutional irritability.

Ulceration, or, in other words, absorption, takes place much more readily in the cellular and adipose substance, than in muscles, tendons, nerves, and blood-vessels. Hence, in the progress of pus to the skin or surface of the body, ulceration often takes a circuitous course. The skin itself being highly organ-
Absorption, with suppuration, in other words ulceration, either happens in consequence of suppuration already begun, in which event the pus acts as a pressure, or when absorption attacks external surfaces from particular irritations or weakness, in which suppuration must follow.

The principal ulcerations to which the horse is most liable are poll-evil, fistulous withers, ulcers of the mouth, and strangles.

**POLL-EVIL.**

This, of all ulcers, in the horse, is the most troublesome to deal with; for, though the veterinary surgeon may complete a cure, the time and expense incurred, neither remunerate him for his applications and trouble, nor do they gain him any credit as a professional man. In this disease, the old farriers went violently to work with all the scaling materials the druggist's shop could supply; but the milder system adopted by the modern veterinary practitioner, has, in a great measure, done away with their unskilful and unsurgical modes of treatment. Still it happens, unfortunately, that this disease is not generally brought under the notice of the veterinarian until the village farrier has expended all his recipes and knowledge; and after all this it is more than ten-to-one, if he has really discovered the part that is affected.

We will therefore endeavour to point out the nature and real situation of poll-evil.

*Poll-evil* is an unhealthy inflammation, which takes place at the back of the ears from blows or bruises, or other injuries which the horse may have sustained on that part. It is frequently found in farm or cart-horses, which are sometimes cursed with evil-disposed carters who, in a passion, will strike them about the head with the butt-end of their whips, or whatever they may chance to have in their hand. We have seen a horse knocked down senseless, with comparatively a slight blow at the back of the ear. Now, there is a mucous capsule at the conjunction of the head with the first bone of the neck, over which passes the *ligamentum colli*, or as the farriers term it, the *pax-fac* of the neck. These parts, from blows or other injuries, contract inflammation, and hence an ill-conditioned ulcer is formed; and from its situation being near the head or knowl, it is called poll-evil. Chestnut horses are...
more susceptible of it than horses of any other colour: at least such has been observed to be the case; and it is attributed to the delicacy of constitution in light chestnut animals, more than to anything else. There is scarcely a case of poll-evil that, either directly or indirectly, arises from constitutional disposition. Hay-seeds about the head may induce the horse to rub, and, in consequence, produce irritation; dragging back in the halter may occasion bruises, and both of these actions may produce ulceration.

Poll-evil, when first discovered, will frequently yield to repellent applications, of which the following may be tried—

Sal-ammoniac . . . . . . . . 4 oz.
Sugar of Lead . . . . . . . . 1 do.
Vinegar . . . . . . . . . . 1 pint.

Apply this lotion constantly to the poll of the head, by keeping cloths on continually wet. In applying the cloth, have it sufficiently large, to allow two holes to be cut in it, so that it may be passed easily over the horse's ears, by which means it will be retained in its place. This cloth can easily be renewed, or with a sponge apply more of the lotion; in the meantime feed on bran mashes, and give—

Cape Aloes . . . . . . . 6 drachms.
Juniper Berries . . . . . . 2 do.
Form with soft sop.

Let a ball, composed of these ingredients be given twice a-week.

Should the tumour appear stationary, and the process of absorption not likely to commence, great benefit has been found from applying a liquid blister, composed of—

Cantharides . . . . . . . 1 oz.
Vinegar . . . . . . . . . 3 do.
Spirits of Wine . . . . . . . 1 do.

Put these together, in a bottle, and frequently shake it. In eight or ten days it will be fit for use. Rub about two table-spoonfuls on the tumour night and morning.

When all hopes of preventing an abscess have ceased, it must then be promoted, by stimulating the skin, and instead of poultices or applications of warm water, the following should be applied—

Oil of Turpentine . . . . . . 2 oz.
Oil of Olives . . . . . . . 2 do.

Rub this well into the swelling, night and morning, until on pressure under the finger and thumb, it is found to fluctuate. When the maturation is perfect, which may be known by the soft feel of the tumour, the next thing to be taken into consideration is, to effect the evacuation of the contained matter, at the most depending situation, to prevent the formation of sinuses. Nothing is so good in this case as introducing setons on both sides of the neck. Should these act well, a speedy cure may be anticipated. But when from improper management, matter has not only formed, but has been suffered to remain, or has only evacuated itself by a superficial opening either natural or artificial, and not from one in a depending situation, whereby a re-accumulation of pus has taken place, the consequence is that the ligaments have taken on disease, which may have extended under the cervical ligament, leaving it hollow below. In such cases the healthy secretion always ceases, and instead of it a thin ichorous or glairy discharge is set up. This ichorous matter penetrates into the interstices of the muscles, when sinuses become formed in every direction, and if not speedily relieved, carries of the bones of the neck is the consequence. From this neglect, or bad treatment of the disease, horses may frequently be seen with what is called a stiff neck, poking their noses and heads out in the most disagreeable manner imaginable. To prevent these effects active measures should be taken. An experienced veterinary surgeon, who can handle the scalpel with dexterity and confidence, should, at once, be called in, and the horse immediately cast. When this has been done, a careful examination should be made with the probe and the finger, that the extent and direction of the sinuses may be ascertained. This should not be negligently or slightly done so as to have a doubt upon the mind, but with the utmost precision and certainty. As you have got the horse confined, and fairly under your command, the most critical examination must be made, for the cure will greatly depend upon this, and the horse, to a large extent, be relieved from unnecessary pain. In making this examination the finger will be found of much more service than the probe; therefore, carefully examine the ulcer with it, more especially, if caries should have taken place; for this must be dissected out before a cure can possibly be expected. Of these things the old
farriers knew nothing; consequently, if they could heal the external opening, they imagined they had accomplished a great feat; and hence the liability of the parts to become diseased again. Hard and callous edges must be removed, and the smaller sinuses laid open, so as to form a cavity. If all this is not thoroughly attended to, and done when the whole seems on the point of healing, a new tumour will suddenly arise as the result of the carious bone, or of some portion of ligament remaining in the abscess. In this case, the experienced veterinarian, who is expert with the knife, and fully acquainted with the anatomy of the parts, will not hesitate how to act. In the hands of the common farrier, much injury has frequently been done from the injudicious use of the knife. Even the cervical ligament has been known to be divided by ignorant pretenders, who having no character to lose, grope on in the dark for the paltry fee of a few shillings, sooner than acknowledge themselves in error. Instead, therefore, of hazarding any of these evils, the practitioner will be justified in this state of the case in introducing setons, even to the number of three or four on each side, going down to the bottom of each sinus, no matter how deep it may be. When this has been dexterously done, dress the setons with the following mild blister ointment, every day:—

Cantharides, powdered . . . 2 drachms.
Hog’s Lard . . . . . 3 oz.

Continue this until the matter becomes of a good consistence. Where cases of great obstinacy occur, and this fails to produce a good effect, stronger means must be adopted. Therefore use the following:

Corrosive Sublimate . . . 2 drachms.
Water . . . . . . . . . 2 oz.

Dissolve the sublimate in the water, and inject the sinuses with the mixture. If this does not produce any amendment, proceed to scalding, in order to overcome the morbid action, and produce a kind of inflammation, from which healthy granulations may follow.

To obtain this try either of the following:

No. 1.
Arsenic, finely powdered . . 2 drachms.
Digestive Ointment . . . . 4 oz.

No. 2.
Corrosive Sublimate . . . 1½ drachm.
Digestive Ointment . . . 4 oz.

No. 3.
Butter of Antimony . . . 3 drachms.
Oil of Tarantine . . . 2 oz.

To render any of the above properly applicable melt either of them in an iron ladle to a scalding heat, and, as the horse lies on the ground, carefully pour the liquid into the wound, putting in, at the same time, a little tow. At the end of four or five days, sloughing will commence. After this apply digestive ointment, and treat as a common wound. If the wound should not be going on satisfactorily apply the scalding composition again. Splints externally applied by pressure, have been found of great benefit in the treatment of Poll-evil. In the fifth volume of the Veterinarian, Mr. A. Gray says, “A mare was sent to me, and I proceeded to examine the extent of the disease. I found two deep sinuses, one on each side of the neck, the bones of which could be distinctly felt with the probe. After cleaning away the matter I took a scalpel and laid both orifices open, in an oblique direction downwards; then, having fomented the parts with warm water, I dressed the wounds with tincture of myrrh and aloe; and, in order to apply pressure to the parts—for in this I founded all my hopes of success—I had two pieces of wood prepared, about twelve inches long and three broad; thicker in the middle than at the edges, which were rounded off, and also a long flannel bandage, four inches broad. I then placed two pledgegs of tow next the wounds, putting on the pieces of wood, one on each side, and then applied the bandage over all, and as tightly as I could, without impeding deglutition. It is necessary while putting on the bandage, to keep the nose extended, in order to adapt the bandage more perfectly to the part, and apply it more closely. I removed the bandage, night and morning, and had the parts well fomented and dressed with the tincture. In the course of four weeks the mare was well.”

FISTULOUS WITHERS.

This disease is, in general, the consequence of neglect, or the careless manner in which the saddle is fixed to the back of the horse. When it is too wide in the trees, the pressure, coming repeatedly on the withers with double force, the parts become bruised and pinched,
and inevitably begin to form matter. It is frequently the case that this is not taken notice of till the evil has been repeated, and bruise upon bruise inflicted, when inflammation and swelling ensue, threatening an unavoidable suppuration. This culpable neglect is sometimes followed by error, for, during the time that the process of nature is going on, and the matter in the tumour forming, the repellent lotion, as prescribed for poll-evil is generally used. Here now begins a terrible struggle between the powers of nature and art; for these applications failing in repelling, or dispersing the contents, have their properties distributed over the integuments, where, by repeated application, an induration is produced very unfavourable to the absence in its more advanced state. Nature, at last, becomes predominant, and effects her purpose. The tumour suppurates and, as a consequence, a discharge comes on, but without one of those advantages that would have been acquired had the efforts of nature been attended to and properly encouraged, instead of being opposed.

This is the origin and progress of what constitutes a confirmed fistula, which falls under the very method of cure described in the case of poll-evil. It should be remembered that all sinuses or cavities into which the probe can be passed should be laid open, taking care to make no transverse opening across the withers, and to avoid dividing the long ligament. Care should be taken to make the incisions on each side, or on both sides, in a longitudinal direction, if it should be required. Should the discharge not assume a healthy appearance, a preparation of the following proportions should be made:

**Digestive Ointment** . . . . 2 oz.
**Red Precipitate** . . . . 2 drachms.

Form into an ointment, and apply every morning to the wound, until the discharge becomes more healthy. Should this application be successful, in obtaining a healthy discharge of pus, try the following, in order to heal the wound as soon as possible:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vinegar</td>
<td>2 oz.</td>
</tr>
<tr>
<td>Compound Tincture of Myrrh</td>
<td>1 do.</td>
</tr>
<tr>
<td>Tincture of Cantharides</td>
<td>1 do.</td>
</tr>
</tbody>
</table>

Inject this mixture to the bottom of the wound two or three times a day, and it will produce a healthy secretion of pus, and promote the healing process. If the lotion is not used, it may be as well to warm the precipitate ointment in an iron laddle, and pour some of it into the wound, so that it may penetrate every sinus that has been formed.

Incisions or scarifications should be made whenever necessary, and all callous, hardened parts dissected out, and, if required, two or three sections passed in the most depending situations. This method should be pursued in preference to any other, unless the wound has been suffered to proceed some considerable time, and a vast formation of proud or fungus flesh allowed to be formed. Then the knife becomes the only remedy. This mode of treatment should have the preference on all occasions; consequently, if the milder method should not succeed in restoring the parts, then the scalding method, as prescribed in poll-evil should be resorted to.

Let it be borne in mind, however, notwithstanding the recommendation of all these remedial measures, that this disease, when first discovered, may be completely removed by repellant applications, but, when bruise after bruise is suffered to go on, and matter to be formed, repellents do more harm than good. If none of the preceding applications should be at all successful, proceed to scalding, such as described under the heading of poll-evil.

If a clean sore can be obtained by cutting open the part freely, and if there are no sinuses, Professor Spooner recommends mild dressings or tents of digestive ointment, tincture of myrrh, &c. These, however, seldom effect a cure, therefore repeated dressings with caustic ointment, must generally be resorted to.

**Ulcers in the Mouth.**

**Ulcers** in the mouth sometimes proceed from the irritation of too severe a bit, or from some sympathetic inflammation, such as a ragged tooth, and frequently from constitutional irritation, when watery tumours, similar to gum-boils in the human subject, frequently appear. As a remedy for this, the following preparation is recommended to be applied to the sores three or four times a day:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spirits of Wine</td>
<td>2 oz.</td>
</tr>
<tr>
<td>Vinegar</td>
<td>2 do.</td>
</tr>
<tr>
<td>Honey</td>
<td>1 do.</td>
</tr>
<tr>
<td>Alum, burnt</td>
<td>4 drachms.</td>
</tr>
</tbody>
</table>

221
Take a small stick, with some linen or tow tied to the end of it, and apply this as often as above directed. As all persons do not know the meaning of burnt alum, make it thus. Buy an ounce of common alum, put it in the fire-shovel, and set it on the fire, when the heat will evaporate the watery matter from the alum, leaving that which is burned, and which is technically called alumen ustum.

STRANGLES.

The apparent sensation of suffocation is the probable origin of the name of this disease, with which many horses are, at some period of their lives afflicted. Although subject to it at all times of life, the periods of attack are mostly when they are rising three or four years old. Horses, at that time of life, are generally taken in from grass, though colts at grass frequently become affected; but animals removed from grass to a warm stable, are much more liable to take the disease, which would lead to the inference that it is the heated atmosphere, combined with the stench of the dung and urine, which produces inflammation and suppuration of the submaxillary glands.

This is brought on, nine times out of ten, when the horse is brought into the stable, either to be broken into saddle or harness. In those cases where it takes place out of doors, poverty is the principal cause, producing extreme debility, and, most frequently, horses so attacked, and in so weak a state, generally, or at least most frequently, become victims to the disorder, and not unfrequently are affected with glanders.

The first attack generally commences with a dull sluggish heaviness and inactivity, the horse becoming dispirited, losing his appetite, having a hollow husky cough, occasioned by the irritability of the inflamed glands, and sore throat. To excite a degree of moisture in the mouth, with the view of allaying this disagreeable sensation, he is often picking his hay, but eating little or none. A degree of symptomatic fever comes on, and a consequent clamminess and thirst is perceptible; but the animal appears to have great difficulty in swallowing water. As the disease advances, he becomes proportionally languid and inattentive. Between the jaws there is an apparent swelling of the glands, which is, at first, very hard, exceedingly painful, and visibly increasing. He now swallows with great difficulty, heaves at the flanks, and his whole appearance urges the necessity of an immediate attempt to relieve nature.

For the treatment of this disease care must be taken not to bleed the animal, unless the febrile symptoms run very high, and then only in small quantities, as would be done in catarrhal affections; for the debility with which it is accompanied will not allow much blood to be taken from him. In almost any case, a couple of quarts should not be exceeded, unless there is much heaving at the flanks, and the pulse is hard and quickened, and the extremities cold. "Unless the symptoms of fever are particularly severe," says Professor Spooner, "and inflammation of the windpipe and lungs is threatened, it is better to avoid blood-letting; and if employed, it should be with moderation. The bowels should be moderately relaxed, for which purpose two or three drachms of aloes may be given in a ball; but rarely, if ever, repeated. Two drachms of nitre, and one of tartarised antimony, may be given twice a day in a mash. He should avoid drenching as much as possible, in consequence of the soreness of the throat. A stimulating liniment should be rubbed on the swelling, and a warm linseed meal poultice applied and changed twice a day."

Use a nose-bag, frequently replenished with hot water and bran, for the purpose of steam ing the nostrils, and promoting a discharge. Should the tumours break inwardly, you will find this of great service. The next thing to be done is to promote the suppuration of the swelling as quickly as possible; but this must not be attempted by poultices. These have a tendency to do much more harm than good, unless there is a man constantly in attendance, for the moment the poultice becomes cold, it acts as a repellent to the tumours, and obviates what is wished to be produced. Take, therefore, of

| Oil of Turpentine | . | . | . | 3 oz. |
| Olive Oil | . | . | . | 3 do. |

Apply this liniment to the throat, and tumours between the jaws, three times a day, having first clipped off the hair close, to allow the liniment to act quickly. Should this not pro-
duce suppuration so speedily as anticipated, use the following:

Caustic Iodidum . . . . 2 drachms.
Oil of Turpentine . . . . 2 oz.
Olive Oil . . . . . . . . 2 do.

Shake well together in a bottle, for two days, and apply as directed in the former.

Either of these applications will produce a speedy suppuration of the tumours, and on feeling them, they will be found to undulate; at this period the lancet may be introduced to let the matter out; but never lance the tumours unless there is a perfect certainty that matter has formed. If the tumour should break of itself, and the opening be small, enlarge it with the lancet. Have the parts now well fomented, and washed with warm water two or three times a day; always remembering to wipe them dry with a linen cloth.

This being done, a hood should be placed on his head, with a piece of flannel to cover the jaws. When the discharge has terminated, and the orifices made with puncturing appear red and healthy, proceed to the healing process, which naturally of itself would take place; but it is necessary to assist nature. To do this, take

Sulphate of Zine . . . . 1 drachm.
Vinegar . . . . . . . . . 2 oz.
Watery solution of Aloes . . . . 3 do.

Dissolve the sulphate in the acid, then add the solution of aloes.

Apply this mixture to the sores, morning and night.

For food, any nourishing diet will be proper; but whatever this is, it must be given in small quantities. Try the horse with half bran and oats slightly wetted; and when he begins to swallow tolerably well, give him a little spayed malt in his feed. This will rouse him from that debilitated state the disease has reduced him to; and to further strengthen his system give the following:

Cape Aloes . . . . . . . . 6 drachms.
Sulphate of Iron . . . . . 6 do.
Gentian . . . . . . . . . . 12 do.
Linseed Meal . . . . . . . . 12 do.

Form into a mass with soft soap, and divide into six balls.

Administer one every second day.

There is a consolation in this disease that a symptom of danger occurs but seldom, and then principally when horses are affected by it at grass, and especially in consequence of their being only colts. At this time they are not brought under the eye of the master so often as they otherwise would be. But if the horse is kept in the stable, the danger generally occurs from neglect, or absolute cruelty, in riding or driving to extremity. When the disease has commenced, and gone so far as to produce fever, and then inflammation, it generally terminates in glanders; consequently the greatest care as to cleanliness is of the highest importance, such as sponging the nostrils well out every morning and evening; and he should be kept warm.

VIVES.

Vives is the name given to strangles, when the parotid gland alone is attacked. How the name arose we cannot now ascertain; but as the disease is generally known by that term, it would be folly to change it in a general work of this kind.

It consists of an inflammation and enlargement of the parotid glands, situated and commencing at the base of the ear, and continued down to the angle of the jaw. By old farriers it is called bastard strangles; but this is an error, for they never suppurate; but occasion great pain to the horse whilst eating, in consequence of the action of the jaw continually pressing on the enlarged gland.

These swellings at times become so fixed, that cough and considerable irritation are produced about the anterior part of the epiglottis, which covers the wind-pipe in the act of swallowing, to prevent food passing down that tube, and when food comes in contact with it, cough is almost sure to take place. In consequence of this, the irritation is frequently so great, that the horse will cough repeatedly, with such violence, that it would lead one to suppose that the rupture of some vital part must be the result.

In this disease, stimulants, in order to promote a discharge, should never be applied, lest there should be left a blemish, which will greatly lessen the value of the horse. The method found best in treating for it is to apply the following:

Ammonia . . . . . . . . . 1 oz.
Olive oil . . . . . . . . . 4 do.
Rub about two table-spoonfuls of this liniment on each gland, morning and night, and take of

Cape aloes . . . . . 6 drachms.
Ginger . . . . . 1 "

Form into a ball with soap,

and give. If the horse's throat should be at all sore, giving a ball is always attended with difficulty; and should this be the case, take of

Glauber salts . . . 4 oz.
Linseed meal . . . 2 do.

Mix the linseed meal with a little cold water first in a basin, then take about a quart of hot water, and dissolve the salts. When this is done, mix altogether, and carefully horn it down. This must be repeated morning and night, until the swelling goes down, and the horse begins to feed better. Should the ball have been given, five or six days should be allowed to intervene before the dose is repeated.

Some animals are extremely awkward, either to give a draught, or to make take a ball. Should such be the case, take of

Sulphur . . . . . . 12 oz.
Glauber salts, finely powdered . 1 lb.

Well work together in a mortar, and give one in the horse's feed morning and night.

For feed, bran mashes should be given cold; but if he should not take to these well, a handful of sweet oats should be mixed with them to entice him to eat. In all cases when sick horses are to be fed, the hands should be free from unpleasant smells, as the senses of the animal are so exceedingly delicate, that the least offensive smell will cause him to refuse all kinds of food, let his appetite be ever so good.

CHAPTER XVIII.

RHEUMATISM.—ANTICOR; LAMPAS; WARBLES; SITFAST; BRUISES; BARBS.

RHEUMATISM.

Rheumatism in horses has, in England, been little treated on; though the French have written considerably on it; and this, in all probability, was the cause of drawing the attention of the veterinarian to the subject.

The disease is characterised by fever, pains in the joints, increased by the action of the muscles belonging to the joint, the disease frequently flying from one joint to another, and this most frequently in young horses. In aged animals the back and loins become the parts principally affected; the horse going stiff, scarcely able to turn, and his legs moving under him more like jointless props than legs. It is frequently preceded by shivering, heat, thirst, and quickened pulse; and some persons, from these symptoms, are apt to think that inflammation of the lungs has taken place. However, the young surgeon must not be deceived by these appearances; for after the above symptoms the pain soon commences and fixes on the joints.

Rheumatism may occur by pain in the joints without fever, and this mostly with coach or hack horses, from being ridden or driven hard, until they perspire very much, and are afterwards allowed to stand in a draft of wind. It may arise also, at all times of the year, especially when there are frequent vicissitudes of weather, from heat to cold. Obstructed perspiration is the principal cause which produces rheumatism. We have an account of a horse affected with sciation, a species of rheumatism, which he suddenly caught. The gentleman to whom he belonged, had been riding rather sharp in the mouth of March. On coming home, he turned the animal into the stable, his groom at the moment being otherwise employed. On the man going to see him, he immediately led the horse to a pond in the yard, to water. Consequently he received a
sudden chill from the water; and the wind being cold at the season of the year, added to the dilatory manner in which grooms at their horses, an attack of sciatica was the result. This was shown by the horse first lifting one hind leg, then the other, and especially in wet weather and after strong exercise. In this case, the horse's urine was always thick and muddy, made in small quantities, and very frequently. This was a case of confirmed chronic rheumatism. The horse was purchased by a coach proprietor for little more than half his worth. He was worked for about five years, but never recovered, and ultimately died of inflammation of the lungs.

This disease most frequently attacks coach and hack-horses in the back and loins. For the treatment of such, abstract about three quarts of blood, according to size and constitution; and if the inflammatory symptoms are severe, give the following:

Barbadoes Aloes, from 4 to 6 drachms.
Ginger . . . . 1 »
Digitalis . . . . 1 »

Form a ball with soft soap.

After the bowels are freely opened, take of
Oil Turpentine . . . . 2 oz.
Olive Oil . . . . 2 do.
Ammonia . . . . 4 drachms.

Apply some of this liniment to the spine, where the stiffness appears greatest, which will, in all probability, be across the loins. Should this not prove effectual, success in the treatment has often resulted from the introduction of setons, one on each side of the backbone, near the loins; dressing, at the same time, with digestive ointment. Before introducing these, cast the horse.

When this disease attacks young horses, it is generally in the acute form; but it is mostly unaccompanied with fever. Colts, about two or three years old, are mostly subject to it, and principally in the winter months, when they are at grass, and the pasture is bad, not containing any nourishment. Acute rheumatism arises as much from debility as any cause, the colt not being able to bear up against the inclemency of the weather. As soon as the lameness is discovered—for here the joints are the principal seat of disease, especially the fetlock joints—have him immediately housed; and should it arise from debility, he must not be bled; for the cold and wet generally are the causes, and he requires tonic medicines to tone and strengthen his system. In the first place, therefore, take of—

Gentian, powdered . . . . 12 drachms.
Anise-seed, do. . . . . 12 »
Liquorice, do. . . . . 12 »
Antimony, do. . . . . 1 lb.
Sulphur . . . . . 12 oz.
Rub well together in a mortar, and divide into twelve packets. Give one night and morning in the feed of the horse. For food, give good hay, and half oats and bran, three times a day.

Apply flannel bandages to all the legs, round the fetlock and pasterns. This, in general, will remove the pain, after having rubbed in some of the foregoing liniment; but the joints must not be bathed, as, by so doing, the evaporation arising afterwards will produce cold, and consequent stiffness, leaving the matter worse than it was at first.

Some of the old farriers have termed this disease, the flying lameness, in consequence of its frequently going from one part to another; but we may remark, that should The Modern System of Farriery fall into the hands of agriculturists, &c., where the term has become familiar, they will then know how to detect and treat the disease.

**ANTICOR.**

This is a disease of the chest or belly, being a species of tumour formed by the debile state of the absorbents; they, in consequence, not being able to perform their functions; hence a serous fluid becomes deposited in the cellular membrane, which greatly abounds in these parts; and the fluid running together to the most pendent part, forms the tumour called anticor, from its being against or near the chest, or the heart. The disease is not frequent in this country, but it is common on the continent. In treating for it, bleeding is not to be recommended; but give half bran and half oats made wet, for corn feeds, and plenty of good hay; then take of

Cape Aloes, . . . . . 6 drachms.
Resin . . . . . 6 »
Sulphate of Iron . . . . . 10 »
Linseed Meal . . . . . 4 »
Mix, and form into a mass with soft soap.
Administer one of these balls every morning. Put an ounce of nitre into the water of the horse every night.

LAMPAS.
This consists of an enlargement or tumefaction of the roof of the mouth or palate, and is particularly to be observed in young horses. In some cases the enlargement becomes so prominent, as to project below the teeth of the upper jaw. This generally occurs when the horse is changing his teeth, or the tasks making their appearance. Another cause is, when horses are first taken from grass—which is, of course, soft food—and then put into a stable on hay and oats, both being hard meat, which occasions the palate to enlarge and inflame. From this cause the horse is not only deprived of a great portion of the nutriment necessary to his support, but he becomes poor, weak, dejected, and altogether out of condition. Its origin has been attributed to the change which takes place on being taken from grass and put into warm stables. This, however, is not likely to be the case, for breeders of horses generally have their stables cool enough.

In treating for lampas, scarification has been recommended; but that operation has not been generally successful, although it has been recommended by many veterinary surgeons. This disease more frequently comes under the notice of the common farrier than that of the surgeon; and by its so doing, custom has established a useful and expeditious extirpation of it by the actual cautery (represented in our Plate of Instruments): and though no advocate for violent remedies where they can possibly be avoided, yet this is a cure so speedily effected by an expert operator, and the suffering to the animal is so very trifling, that when a comparison is drawn between the temporary inconvenience and the immediate advantage, no hesitation can be made respecting the operation.

When the operation has been performed, the horse should be allowed to wash his mouth out with clean water; and nothing should be applied to the wound, which will heal of itself in a few days. If an application is made, it will only increase the pain of the animal, and in a few seconds he will have it all licked off again.

WARBLES.
These are swellings or tumours formed on the sides or some part of the back, in consequence of the unequal pressure of the saddle. They may also arise either from the excessive heat and friction, or the edge of a narrow saddle-cloth coming directly under the seat of the rider, and not unfrequently from the girths being too short, and the buckles at either one side or the other being set below the saddle pannal. If the pressure is repeated, and the groom does not perceive it, the tumour will sometimes suppurate. A sore will be the consequence; and it will probably be somewhat troublesome for several weeks.

As soon as the tumours are perceived, and before matter is formed, the following repellant should be used several times in the course of the day, and applied to the tumour, with a piece of sponge—:

- Sal-ammoniac ... 2 oz.
- Sugar of Lead ... ½ do.
- Vinegar ... 1 pint.
- Water ... 1 do.

The horse must have perfect rest in a loose box or barn, and a saddle or anything irritating must be kept from him. If the tumour remains hard, and has no appearance of going away, it then becomes what is termed

A SITFAST.

For this there is only one certain and expeditious cure. All applications in the shape of blisters, liniments, &c., meant to soften the tumour, will avail nothing. Therefore, take a scalpel, and dissect the tumour completely out, and dress with common digestive ointment, in which has been rubbed down a little red precipitate. When this has brought the wound to a healthy appearance, treat it two or three times a day with compound tincture of myrrh.

If, in the first instance, warbles should break, wash and dress first with the ointment as above, and then heal with the tincture. In the meantime, let the saddle pannal be altered, that a recurrence of the accident may not happen.

BRUISES.
These consist of tumours, which are formed by external injuries, such as kicks from other
horses, or passionate groom, on the legs and other parts of the body. If the bruise is slight, and even though lameness is the result, it frequently becomes reduced almost apparently of itself; but if the injury should be severe, the extravasated blood will then become a source of pain and irritation. In some cases the blood is thrown out instead of becoming absorbed; coagulates, and, at length, becomes vascular, when the enlargement remains permanent.

The treatment of bruises varies according to circumstances. If the case is not too severe, take of

Camphor . . . . . 1 oz.
Spirits of Wine . . . . 8 do.

Dissolve the camphor in the spirits, and rub on a portion every morning and night, or take

Brandy . . . . . 4 oz.
Vinegar . . . . . 4 do.

Mix, and apply as above. If the bruise is in such a situation as will admit of a bandage, never omit it—flannel is the best. If the tumour remains hard and unyielding to the above treatment, stimulate the absorbents by applying mercurial ointment, well rubbed in for three or four days; after which apply a blister. Should this not succeed, recourse must be had to firing.

BARBS.

These are small tumours situated under the tongue, and frequently the cause of much pain, so that the horse, without great difficulty, cannot masticate his food. They are easily seen on drawing the tongue on one side, where two little prominences make their appearance. They arise from an inflammatory action, existing in the salivary ducts, produced either from symptomatic or local fever, and are generally attended with a large flow of saliva. The farriers of former days used to recommend their being entirely removed, by nipping them off with a pair of scissors; but there is no necessity for this. The following treatment will do away with them. Take of

Alum . . . . . 1 oz.
Water . . . . . 4 do.

Dissolve, and apply with a bit of sponge, tied to the end of a stick, several times a day. Give the horse an ounce of nitre in his water, for about five or six mornings, and a reduction in the enlargement will soon be perceived; and by-and-by they will altogether disappear.

CHAPTER XIX.

STONE.—STONE IN THE INTESTINES; THE KIDNEYS; THE BLADDER.

STONE IN THE INTESTINES.

The horizontal situation of the body of the horse, and the nature of his food, render him particularly liable to concretions in the intestines, which generally take place in the colon, from a peculiar curvature which this has of doubling on itself. At this curve, stone is usually found.

Most of these concretes, however, are in their beginning composed of salubrious matter, which first collects around some accidental nucleus, as a nail, or stone. It also very frequently occurs amongst millers' horses, from a portion of the grinding-stones, by friction having become mixed with the food upon which horses are commonly fed. From frequent deposits of a portion of the alimentary contents coming in contact with the nucleus, layer upon layer becomes formed, until, in some cases, they are of an enormous size. These calculi, in many instances, are so dense and hard as to admit of a fine polish; while some are of a softer nature, and appear more like indurated dung, and will break easy. Hair balls have frequently been found in the intestines, especially in neat cattle; and are very troublesome, being the cause of great inconvenience.
Horses do not appear to suffer so much from calculi as might, at first, be expected; and then the disease only appears like an attack of gripes, caused by some obstructed dung in the intestine, giving pain. When the passage is rendered free, the pain immediately ceases. Calculi frequently, or always, however, bring on a fatal strangulation, and consequent inflammation. In such cases the horse usually falls a victim.

The cure of this malady is out of our power, and its prevention is little less so, unless we perceive the horse addicted to eat roots or lick up the earth, to which he is sometimes given. The only chance of prevention, then, is to give bran mashes for a day or two, until his dung becomes moist. If in regular work, let him resume his usual food.

STONE IN THE KIDNEYS.

Stones sometimes form in the kidneys, or in their cavities. In the horse they accumulate till they fill the whole of the cavity; and we have heard of a case, in which, from the inflammation produced thereby, the kidneys became totally absorbed, and a large tumour was formed in their place. This animal could with difficulty walk: he was accordingly ordered to be destroyed; and on opening him, it was found that the right kidney had become a complete stone.

STONE IN THE BLADDER.

Though this disease is not so frequent in the horse as in the human subject, still we have no doubt of its occurring more frequently than is generally supposed. This is made pretty evident at the yard of the knacker, for very many calculi are there found, after death, in the bladder. The symptoms of its presence are frequent inclination to make water, voided in small quantities, and accompanied with excessive pain. Sometimes a sudden stoppage of it takes place; and this is very frequently attended with extremely sharp spasmodic pains. The horse then walks wide behind, or appears loth to move along, and occasionally reels about, with a staggering gait. The remedy was discovered, and, we believe, first brought into practice, by Mr. Sewell. The presence of stone in the bladder is not very difficult to discover; for, if we examine the bladder, and introduce the hand up the rectum, and feel for the bladder, just beyond the bone called the pubis, there it will be met with. When this is the case, try whether there is any hard substance present. If so, it is stone in the bladder.

For the removal of the substance, introduce a long, well oiled whalebone staff up the urethra, until the end of it is felt just under the anus; then take a scalpel, and cut perpendicularly down upon it, and enlarge the opening to about an inch and a-half. Into this opening pass a long whalebone probe, or, as it is called, a sound; the end of which will be felt to strike against the stone. Being satisfied of this, withdraw the instrument, and introduce your forceps, for the purpose of extracting the stone. If the opening should not be large enough, take a concealed history, and cut up a little, as the horse is supposed to be lying on his back. Then endeavour to seize the stone, and withdraw it whole. Should this not be practicable, the stone must be taken hold of by degrees, and broken down by means of the forceps. Then withdraw the pieces, and empty them. Continue to do this until perfectly satisfied that the whole of the stone is removed. This being done, inject warm water into the bladder, which will give the horse great ease. He may now be allowed to get up, when, in all probability, some sediment and urine may escape from the wound for a day or two. This need not occasion any alarm; but continue to bathe the parts two or three times a day with warm water. After this time, the wound will close, the urine pass off in its natural channel, when the wound should be treated as a common one, by applying to it, twice a day, compound tincture of myrrh. Should the horse take on any appearance of fever, give him, in his feed, with half bran and oats, made slightly wet—

<td>Digitalis</td>
<td>6 drachms</td>
</tr>
</tbody>
</table>

Mix, and divide into twelve powders. Administer one in his feed every night.

With mares the operation is less difficult, as the parts may be dilated instead of being cut; but to them the use of a round-headed catheter, sufficiently large in the bore to allow the sound to pass through it, is recom-
mended. When this is introduced, and the urine drawn off, pass the sound down the catheter into the bladder. Having accomplished this, withdraw the catheter, and having satisfied yourself of the calculi being there, proceed as before directed for a horse.

This operation does not generally fail if conducted with sufficient care.

CHAPTER XX.

WORMS.—WORMS IN GENERAL; JAUNDICE, OR YELLOWS; DIARRHOEA, LOoseness, OR SCOURING; CRIB-BITING.

WORMS IN GENERAL.

When worms have secured a settlement in either the stomach or intestines of the horse, he becomes a prey to perpetual annoyance, till effectual methods are taken for their total extirpation.

There are three kinds of worms to which the horse is liable; first, the long white worm, very much resembling the common large earth-worm, but much longer and harder. At its middle it is about the size of a large swan-quill, and regularly tapers off to the ends. The length of these worms varies from six inches to twelve, and they generally occupy the small intestines, and are at times exceedingly troublesome, frequently occasioning gripes, and not unfrequently inflammation, by their excessive irritation.

Another kind of worm is the small thread or needle-worm, which is frequently found in all the intestines, but more particularly in the large. It has also been found in some of the blood-vessels, in the windpipe, and in the lungs. This worm occasions great disturbance in the system when it becomes numerous, but not to the same extent as the last named.

There is a third kind of worm, called bots, which comprises two species. For almost all we know of this worm, we are indebted to Mr. Bracey Clark. Its history is simply this:—A species of gad-fly, "the *cestus equi*, is, in the latter part of the summer, exceedingly busy about the horse. It is observed to be darting, with great rapidity, towards the knees and sides of the animal. The females are depositing their eggs on the hair, and which adhere to it by means of a glutinous fluid, with which they are surrounded. In a few days the eggs are ready to be hatched, and the slightest application of warmth and moisture will liberate the little animals they contain. The horse, in licking himself, touches the egg; it bursts, and a small worm escapes, which adheres to the tongue, and is conveyed with the food into the stomach. There it clings to the cuticular portion of the stomach, by means of a hook on either side of its mouth; and its hold is so firm and so obstinate, that it must be broken before it can be detached. It remains there, feeding on the mucus of the stomach during the whole of the winter, and until the end of the ensuing spring; when, having attained a considerable size, and being destined to undergo a certain transformation, it disengages itself from the cuticular coat, is carried into the villous portion of the stomach with the food, passes out of it with the chyme, and is evacuated with the dung. The larva, or maggot, seeks shelter in the ground, and buries itself there; it contracts in size, and becomes a chrysalis, or grub, in which state it lies inactive for a few weeks; and then, bursting from its confinement, assumes the form of a fly. The female becoming impregnated, quickly deposits her eggs on those parts of the horse which he is most accustomed to lick, and thus the species is perpetuated."

A horse affected with worms will be known by a dry yellowish matter adhering to the fundament, and running two or three inches down below. This is merely the soft part of
the worm, which, in making its escape, irritates the sphincter muscle, and becomes crushed. This frequently occurs in cart-horses. Worms are also often to be detected in the dung, especially the thread worm and the long white worm. The long worm is too strong in itself to be crushed by the sphincter, and the thread worm is too small for any impression to be made on it. There are other symptoms which indicate the presence of worms in the horse. For example, they occasion irregular appetite; render the bowels at one time costive; and, as irritation arises, making them again loose, with an unhealthy secretion attached to the dung. When bots are prevalent, the animal is frequently rubbing his tail against the sides of the stall, or against a post, and betraying many symptoms of a restless uneasiness.

The long white worm is very hurtful. Horses affected with it may eat well, and appear hearty, but they do not thrive. They become hide-bound; and in consequence of the skin sympathising so much with the stomach, the coat stares, and feels rough. This worm is very frequently attended with a short dry cough; sometimes it produces gripes, with hot breath, which smells very disagreeable.

For the treatment of worms, there are but two articles that any reliance can at all be placed in, and that can lay claim to approbation; and one of these is calomel. Antimonials and preparations of tin have each their advocates, and so has train oil. A few of the products of the vegetable kingdom, in the opinion of some, are never-failing, such as rue, savin, box, &c., and also tobacco. Experience, however, has determined the specific effects of calomel in this case as absolutely infallible, before the power of which every species of worms and their oviparous remains, indiscriminately fall, and are totally exterminated without the shadow of a doubt. So soon, therefore, as they are suspected, or at least so soon as they are ascertained to have taken possession, it will be prudent to prevent a horse from getting injured in his appetite, reduced in flesh, or altered in condition by their constantly preying upon the contents of the stomach or alimentary canal. To do this, first prepare him as for a dose of physic, by giving bran mashes, &c., and let the dose be adapted to the strength, size, and condition of the subject by these rules. If

---

THE HORSE, AND

[worms.

the horse is thorough bred, and delicate in form, take—

No. 1.

Calomel . . . . . . . . . 1½ drachm.
Linseed Meal . . . . . . . 2 do.

Form the ball with honey.

In administering this ball be particular. Give it the last thing at night; then put the setting muzzle on, and let the horse remain without food until the morning, when give a warm mash of bran. Replace the muzzle; and when leaving him, give a handful of sweet hay. Proceed in this manner until about six o'clock at night, when administer the following:—

Barbadoes Aloes . . . . . 5 drachms.
Gentian . . . . . . . . . . 2 do.

Form into a ball with honey.

Put on the muzzle again, and by the time you visit the stable in the morning, it is ten to one but the physic has operated. He must now be treated—but with the greatest care—as in the ordinary course of physic. Probably the reader may not at first imagine why the calomel is recommended to be given alone; but a small quantity of this medicine so given, eighteen hours before the aloeic medicine is given, is not only more efficacious locally, but the whole system becomes impregnated with it. Another thing, superpurgation is not so likely to supervene. There is also another reason; the horse will purge without being taken out to exercise, which when exhibiting calomel is very advantageous, as he does not run so much risk of taking cold. After the lapse of about five or six days, repeat both the balls, as directed above; but do not increase the quantity of the calomel or aloes, until the operation of the second dose has been observed, when a judgment will be able to be formed whether the aloes will require increasing or decreasing in quantity. If the horse should want it, or you think the worms are not altogether dislodged from their hold, give a third dose.

If the animal is strong in make, and more like a hackney or coach-horse for size, he may be given,

No. 2.

Calomel . . . . . . . . . . 2 drachms.
With the aloeic balls increased 1 do.

Proceeding as before laid down.

Should he be a large, strong, and foul wagon-horse, the calomel ball may be increased to
two drachms and a-half; and if a very large horse, even to three drachms, and the alectic ball in proportion. By proceeding in this course, the subject will, in a few days, with proper care and attention, and good food and exercise, be freed from the insects with which he has been tormented.

As there will, however, most undoubtedly, be horses, troubled with worms, in the possession of those who, from the nature of their vocations, cannot submit them to so long a respite from business as is necessary for a regular course of the preceding medicines, it will naturally be expected that an effectual substitute should be held forth for the satisfaction of all parties: consequently, we now come to the second remedy, which has been found very efficacious in expelling worms.

Glauber’s Salts 4 oz.
Linseed Meal 1 do.
Hot Water 1 quart.

First mix the meal in a little cold water, to prevent its getting lumpy; and when sufficiently worked up, put it into the salts and hot water. Give this draught with a horn every morning fasting, for six successive mornings. The horse may go to exercise, or slow work of any kind. If he should be perceived to perspire a good deal, and appear faint, discontinue the medicines for a few days; then commence again, until satisfied the worms are completely removed.

JAUNDICE, OR YELLOWS.

This is a disease usually called yellowes, and is common to horses of every description. It arises from various causes, the most material of which we shall endeavour to explain.

The more simple and least dangerous complaint passing under this denomination, arises solely from an obstruction in the biliary ducts; for the horse has no cystic duct, or gall-bladder, like most other animals. By this obstruction the bile does not flow into the intestines, where, by its peculiarly stimulating property, it excites the peristaltic motion by which they expel their contents. The bile thus impeded in its usual progress, becomes absorbed, incorporating itself again with the blood, and, through the system of circulation, diffusing itself over every part, and denoting its presence by an early appearance of yellowness in the eyes, mouth, tongue, and saliva. To these invariable symptoms may be added, those not altogether so certain in their early state— a general heaviness and dulness, accompanied with loss of appetite, and consequent rejection of food; the animal taking little more than will barely sustain nature. All this is attended with a slight symptomatic fever, which keeps pace with the disease. A sluggishness, or aversion to motion, is plainly perceptible; a foul, faint sweat appears upon the least exercise, and the urine is of a dark brown, or saffron tinge: the dung varies much in different subjects, but is, in all, many degrees paler, and more undigested than that of horses in high condition.

The indications of cure naturally arise out of the very description of the disease, to effect which there will not be considerable difficulty, provided it be taken in its early stage, when it may, most probably, be totally removed by the following:—

Cape Aloes 12 drachms.
Calomel 6 do.
Liquorice, powdered 6 do.
Linseed Meal 2 do.
For into a mass with soft soap.

Divide into twelve balls, and give one every second day. Give the horse half bran and oats wetted for morning and evening feed, and scalded bran mashes for his middle-day feed. If the bran mashes do not sufficiently relax the bowels, give occasionally a clyster of warm water, into which throw a handful of salt.

During this course of medicine, every attention must be paid to appetite, food, and gentle exercise. Mashes of malt and bran may be occasionally given at night, to keep the body lax, and not suffer it to get too much debilitated, but to make the evacuations regular.

The disease, if arising from the cause before mentioned, and treated in its infancy, will generally submit to the above course; but in more advanced cases, double the quantity may be required; and, in addition, three or four quarts of blood taken from the animal will be found highly beneficial. In almost all cases, however, the above balls will be found to have the desired effect. Should you not be so fortunate, or the disease happen to be in a large cart-horse, increase the dose of ales a little,
according to circumstances. If the horse should be weak and emaciated, decrease it a little. After the medicine has completely set, and the animal appears to be going on well, give the following:

**Cordial Ball.**
- Anise-seeds . . . . 1 oz.
- Ginger . . . . 1 do.
- Liquorice . . . . 1 do.
- Caraway Seeds . . . . 1 do.
- Treacle sufficient to form the mass.

Give an ounce of this mixture every morning fasting. Should the subject be a cart-horse, increase the quantities of each, and give an ounce and a half for a dose.

During the time of taking this, let the former instructions relative to food, exercise, dressing, &c., be strictly adhered to, with such other attentions as circumstances may require, remembering to relinquish the medicine every second morning, or once in three mornings; but not to discontinue it entirely till all symptoms disappear.

A distinct kind of this disease, arising from a remote and very discouraging cause, is that which originates in an induration, or schirrrosis of some part of the liver, and which will be indicated by pressing the hand sharply against the region of that organ on the right side. In this species there is little or no hope of obtaining a cure. We can only palliate the disease. The first thing to be done, is to extract blood, to the quantity of three, four, or five quarts. This is of course premised to reduce the contents of, or take off some degree of stricture from, the vessels. Remove obstructions of the body by mashes of bran and pared barley, for two or three days previous to administering any medicines.

When the bowels are pretty lax, give
- Calomel . . . . 6 drachms.
- Antimony . . . . 6 oz.
- Sulphur . . . . 6 do.

Rub well together in a mortar, and divide into six powders. Give one of the powders in his feed every other night, first having slightly sprinkled the corn with water. On the intermediate days, in the mornings, give
- Glauber Salts . . . . 3 oz.
- Linseed Meal . . . . 2 do.
- Cream of Tartar . . . . 1 do.

Dissolve the glauber salts and cream of tartar in a quart of warm water, then add the meal, being first mixed with a little cold water. Horn this draught down carefully; and if the disease appears to be removed, give a course of the cordial ball, as directed in the preceding case.

**DIARRHŒA, LOOSENESS, OR SCOURING.**

This disease is indicated by a weakness in the absorbents to take up the watery matter secreted within the intestines; consequently, an increased action of the peristaltic motion is set up to get rid of this watery fluid; and from this cause the evacuations of the dung are produced in a liquid form. It is not like dysentery; for here the purging, from the first, continues until arrested, the dung also being in a constantly fluid state, there being none of that slimy matter attached to it that is in dysentery. There is little or no fever connected with this disease; and if the pulse should at all become quick or hurried, it proceeds more from debility than from any other cause.

This is different in those horses which are likely to purge from excitement; for many horses, full of good keep, with their bowels regularly open, sufficiently healthy, on going to hounds, commence purging instantly. This must spring from nervous excitement. Some horses, more especially light chestnut ones, are liable to purge from the least excitement. Flat-sided, long, lank-legged animals are more subject to intestinal, and other internal diseases, than any other kind of horses. In diarrhœa, however, the horse appears dull, heavy, and inactive, seemingly oppressed, and visibly overloaded, though without any appearance of pain, but subject to general disquietude; whilst the discharge is large in quantity, dark in colour, and fetid in smell.

Diarrhœa seems to depend on an increase of the peristaltic motion, or of the secretion of the intestines; and besides the causes already enumerated, it may arise from many others, influencing the system generally, or the particular seat of the disease. Of the former kind are colds, checked perspiration, excitement, and other disorders, drastic cathartics, spontaneous acidity, &c. In this complaint, each discharge is usually preceded by a murmuring noise, with a sense of weight and uneasiness in the hypogastrium; and then a horse
is called wash-bellied. When it is protracted, the animal loses his appetite, his countenance becomes dull, the skin generally dry, hard, and the coat staring. Ultimately great debility and emaciation, and swelling of the legs, often supervene. Sometimes the disease arises from ulceration of the surface of the intestines. The bile also, from some peculiar change in its nature, occasioned principally by bad food, will produce diarrhœa. The disease, though not so much thought of as it ought to be, is the cause of many a valuable animal becoming a victim, from improper treatment; for some people are apt to go to the other extreme, and administer a long list of astringents to stay the purging, which is highly improper. Debility, and debility alone, is the cause of diarrhœa, let it be brought on by whatever means it may.

For its treatment, first, a proper attention should be paid to the food of the animal, such as his hay and corn, which ought to be of the very best quality. Then give of

- Blue Pill . . . . 1 oz.
- Sulphate of Iron . . 16 drachms.
- Glauber Salts . . . 16 do.
- Liquid Laudanum . . 16 do.
- Linseed Meal . . . . 16 do.

Mix the sulphate of iron with the glauber salts together in a mortar, and pound them very fine; then add the other ingredients, working them well together.

Divide into twelve balls, and give one morning and night.

Boil a teacupful of rice, until it is entirely soft; then squeeze it through a thin tamis, or cloth, and give it in the horse’s water to drink.

Should these means not succeed, give the following:—

- Sulphate of Iron . . . . 12 drachms.
- Arsenic . . . . . . . 1 do.
- Gentian . . . . . . . . . 12 do.
- Cape Aloes . . . . . . . . 12 do.

Mix well together, and form into a mass, with soft

soap.

Divide into twelve balls, and give one every morning.

By pursuing this course of strengthening medicine, the horse will speedily regain his appetite, and his usual courage and power. In some cases it is recommended to give a few cordial balls, as prescribed in the foregoing case, at intervals, until the disease is entirely removed.

**CRIB-BITING.**

The peculiar action of crib-biting cannot be mistaken, on seeing the horse that has it, feed; for, at every swallow, an eructation is produced, which, by making the edge of the manger a fixed point, he is enabled to do with ease. This has, by some writers, been said to be exceedingly painful to the animal; but, very frequently, we find crib-bitters not only high-conditioned animals, but fat; and whatever creates pain, cannot produce fat. Still there is a difference in crib-biting horses. Some will crib badly, and get fat; others will become lean; and this appears extraordinary at first sight, but is of great importance; for, as the horse keeps in flesh or condition with crib-biting, or falls off, so will he be sound or otherwise.

The disease, or habit, more properly speaking, takes place mostly in young animals; and here our opinion differs from many others; for we think it is frequently occasioned by uneasiness in cutting the breeding-teeth. Sometimes the cause is, from horses being ill-fed, when they are particularly hungry. Many animals wear away their fore teeth to such a degree that these will not meet, which arises from the inability to gather up their food. But there is one decided symptom of taking in air, and expelling it also at the same moment; for, if it is observed that the horse, while swallowing, expels air, and at the same moment inhales fresh, it is shown in the operation by the expansion of his nostrils.

By some writers, crib-biting has been described as similar to dyspepsia in the human subject; but this is impossible, or how would one horse take it from the other standing in the same stable?—which we have known frequently to be the case; and it is a well-known fact, that no training groom will allow a crib-biter to stand in his stable. We could give numbers of instances to prove the propensity of its being infectious, having had upwards of one hundred and fifty hack horses at one time, and four or five of them rank cribbers. There have been persons who have attempted to introduce cures for crib-biting, but they have not always proved infallible. One is, to buckle a strap round the neck of the horse tightly,
animals are rarely subject to have much hay given them; consequently, the stomach never becomes so full as when it is distended with natural food, such as hay or grass only; for we never heard of a crib-biting horse at grass or on hay only. The real cause is found in a spasmodic affection of the diaphragm, generally produced by an error in the dietary of the animal; for if you feed with a considerable quantity of corn, and little hay, crib-biting is produced, and vice versa.

To obviate this affection, the whole of the veterinarians have been equally puzzled. Some years ago, a Mr. Yare invented a kind of muzzle, through which the horse could eat, but was not enabled to seize the manger, in consequence of two iron bars being fixed longitudinally to the mouth part. This invention, however, like many others, entirely failed; for, when removed, the horse would take to his old habit again. Prepared chalk, in two-ounce doses, has been tried, but with no better success. The only thing found, in the shape of a palliative, has been to remove the horse thus affected into a stable by himself, without manger, stall-sides, or anything he can take hold of; and give all his food on the ground, both hay and corn. By this means this troublesome affection has been removed in a great degree, though an entire cure has not been effected.

CHAPTER XXI.

DROPSY—OF THE HEAD; THE CHEST; PERICARDIUM; BELLY; SKIN; SWELLED LEGS.

DROPSY.

Drospy is a preternatural collection of serous or watery fluid in the cellular substance, or different cavities of the body. It receives different appellations, according to the particular situation of the fluid.

When it is diffused through the cellular membrane, either generally or partially, it is called anasarca.

When it is deposited in the cavity of the cranium, it is called hydrocephalus; when in the chest, hydrothorax; when in the abdomen, ascites; and when within the scrotum, hydrocele.

We thus particularly enumerate the special names this disease takes, in accordance with its situation, that the reader may not be led astray by the pretender, or country farrier. These diseases are of a family nature, and principally originate in debility: such as long-con-
timed evacuations, the suppression of urine, the sudden striking-in of eruptive humours, the obstruction of the lungs, exposure for a length of time to a moist atmosphere, laxity of the exhalents, defective absorbents, topical weakness—in which case it is most frequent; and, indeed, it may arise from anything that produces debility.

**DROPSY OF THE HEAD.**

This affection does not frequently attack the horse; but when it does so, it is very likely to puzzle the young practitioner, as he may be apt to take it for the staggers, the symptoms being very like those which appear in that disease. Water in the head, when it occurs in the horse, is generally in consequence either of injuries done to the brain itself, or of blows from falls, or from seirrious tumours, or excrescences within the skull, from original laxity, weakness in the brain, or from general debility, and an impoverished state of the blood.

With respect to its proximate cause, very opposite opinions are still entertained by many clever writers; which, in conjunction with the equivocal nature of its symptoms, prove a source of considerable embarrassment to both old and young practitioners. Some believe it to be inflammatory, and, in consequence, bleed largely. Slight inflammation, in the first case, may cause a deposition of fluid on the brain; but this inflammation has, by its effects, produced debility. A torpor of the absorbent vessels may also occasion the disease, and a consequent debility in those vessels to perform their functions.

It sometimes happens in horses that are brought up immediately from grass, and ridden rather sharper than they ought to be, which causes congestion of the brain; but as we shall have to speak of that disease in its proper place, we will now enter on the symptoms of dropsy in the head.

When a horse is attacked with this, he refuses his food, hangs his head down in the manger, is dull, and seems careless of all kinds of nourishment; hanging himself forward, resting his whole weight on his fore legs, looking as if he was going to sleep, and wanted rising up.

When these symptoms appear, a reason must be found for their cause. If they appear in a farmer's horse, not having been recently ridden, it may naturally be concluded that it is congestion of the brain, which may exist without any visible pain or pressure. Should this be the case, the animal must not be bled, but take of

- **Watery solution of Aloe** . . . 1½ oz.
- **Nitre** . . . . . 2 do.
- **Lime seed Meal** . . . . . 2 do.

Mix for a drink, and give immediately.

Let the horse have plenty of room, such as a loose box, or bay of a barn. Let him have plenty of straw, in case he should lie down, and be inclined to roll or knock himself about. Should this treatment not appear to relieve him, apply a blister to the poll or back of the neck, composed of

- **Cantharides** . . . . . 2 drachms.
- **Hog's Lard** . . . . . 2 oz.

Let this ointment be well rubbed in behind the ears.

Should the disease be occasioned by blows, or falls, &c., examine the head well for any convincing proof of the pain that may be existing there. Should there be evidence of this, do not hesitate immediately to open the temporal artery, and abstract as much blood as you can, without the horse's fainting. Should he begin to tremble, it is time to leave off, for the object has been gained.

Secure the tremble in the following manner:—

Have a curved needle, armed with doubled whitish-brown thread, and take up the lips as directed in sutures; then lay a pledget of tow over the orifice, tie up the suture, and the bleeding will be stopped.

For feed, give very little, or no hay, but bran mashes. Do not give any corn. We recommend bleeding, if the disease arises from blows, because this is most likely to stimulate the absorbents to perform their natural functions. For the medical treatment, proceed as before directed.

**DROPSY OF THE CHEST.**

This, as a primary affection, is not common in the horse; but, as a secondary attack, is frequent, and more especially in an attack of inflammation. It consists of a collection of fluid within the cavity of one or both of the pleura;
and when this is the case, there can be no doubt of its arising from debility. Many gallons of fluid have been found so formed within a very short space of time; in some instances pus has been discovered; in others, matter and other coagulable masses.

The causes of this disease are found principally to be connected with the termination of inflammation of the lungs, and are generally to be discovered by the peculiar action of the horse in breathing, and even in his method of standing—straddling wide with his fore legs. Not unfrequently his breathing is accompanied with a jerk; and if close attention is paid, the water in his chest may be heard to make a sudden noise, as if disturbed. This arises from the lungs taking in air, and, in consequence, becoming dilated, and occasioning the rumbling noise in the chest with the water. Horses that are ill-treated, and have bad keep, will sometimes have dropey of the chest, when little or no inflammatory action has been going on. Such as have it from these causes, may perform slow work for some time without the disease being discovered, the poverty of the masters not enabling them to procure assistance in time, whereby bad condition is produced in the horse, and consequent debility, until nature takes compassion on the poor animal, and finishes his career in death. On opening the animal, a quantity of yellowish serous fluid is found floating about his chest, the lungs are contracted and smaller, on account of the fluid interfering with them in the cavity, when the horse is then pronounced rotten.

In treating for this disease, care must be taken not to determine too hastily on bleeding; for this should never be done, even though the pulse is quick, for the quickness is in consequence of debility, and not arising from fever. When the affection is formed, it is seldom or ever that any inflammatory action remains; consequently, blood-letting would be highly injurious, and the result would prove that the cause had been mistaken for the effect. Experience, of course, is the best guide in such cases.

Medicines to promote nausea are frequently said to have a good effect; but we have not found this to be the case, although we have tried them several times, such as white hellebore, in two-dram doses, every five hours. In administering the following, however, our most sanguine expectations have been realised.

Form into a mass with soft soap.

Divide into twelve balls, and give one night and morning.

Rowels and setons sometimes do good in this disease, but they are so long in acting that we would recommend blistering the sides and chest in preference. Give the most nutritious food possible; oats, with a few beans in them for corn, with the best old hay, and let oatmeal, or rice, be boiled in the animal's water. Should the above remedies fail, the last resource is to puncture, or tap the chest. Although this operation is delayed almost to the latest period of the disease, and very unfrequently succeeds; still we have been successful in a cure, when driven to this extremity. The earlier it is performed, however, the greater the probability of its having the desired effect.

We will now describe the mode of performing the operation.

The situation most eligible for the opening, is that wherein a depending orifice may be gained for the complete evacuation of the water, without danger of wounding important parts by the puncture. If it is carried too low, the mediastinal folds, or even the pericardium may be endangered; but this would only occur where the puncture was attempted perpendicularly, so as to make it between the cartilages of the ribs; but in either of the costal openings, between the seventh and tenth ribs, about an inch above their termination into cartilage,* an opening may be first made by a scalpel, towards the anterior edge of the rib, to avoid wounding the intercostal vessels, first drawing the skin a little forwards or backwards, to ensure a future closing to the access of air. Having done this carefully, introduce a three-inch trochar, by penetrating the muscle between any of the above-mentioned ribs; then withdraw the trochar, and allow the cannula to remain in until the whole of the fluid is drawn off. Having performed this operation, and the discharge of the fluid

is such as to carry conviction that you were correct in your judgment, puncture the opposite cavity in a similar manner. If the dropsy, or accumulation of fluid is fully formed—that is, if one or both cavities are nearly filled with serosity—less caution is necessary in the introduction of the trochar; and if the operation is performed early in the disease (which, in general, it should be, to ensure success), then it is necessary to proceed more cautiously, to avoid puncturing the lungs.

Having introduced the trochar only so far as to observe the gush of fluid, put the cannula forward, and retract the other so as to have the cannula alone in the orifice. The cannula must be pushed up to its collar, where it will remain until the fluid is all drawn off.

Coagula, or even the inflation of the lungs, is sometimes found to obstruct the flowing of the latter portions of the fluid. To obviate this, introduce a probe into the cannula occasionally, until you are satisfied that the whole has come away.

When the whole of the fluid has been withdrawn, take out the cannula, and close the orifice by adhesive plaster, or by the common suture. You must not think of performing the operation a second time, although this is frequently done with the human subject; for having drawn off the fluid, reliance must be placed on the medicine before prescribed. Should water again accumulate, the debility will be so much the more increased, and the natural consequence will be that the animal will sink under the disease.

DROPSY OF THE PERICARDIUM.

Dropsy of the pericardium is an increased collection of fluid in the sac surrounding the heart; therefore called dropsy of the heart. The symptoms are the same as in the preceding case; but there is no means of cure for it; therefore, we must submit to nature in this case, and allow her to perform her own operations, obeying her laws.

Frequently the veterinary surgeon is blamed, in this disease, for the losing of an animal which it was impossible to preserve.

DROPSY OF THE BELLY.

This, like the last-named disease, seldom occurs in the horse; but when it does, there is frequently great difficulty in detecting it. It may take place after inflammation of some of the abdominal viscera; and consists of an increased deposit of fluid within the cavity of the belly. Here is formed what is called the peritoneal sac, only of such dimensions as to hold its natural organs, such as the stomach, liver, intestines, &c. If water escapes into this cavity, it at once becomes a foreign body, and is known by the tension of the abdominal and by the undulations which are felt by one hand, when the belly is gently struck by the other. Also, if the car is placed on one side of the belly, and some person desired lightly to force the opposite with the hand, the undulating motion of the water will be heard perfectly distinct.

In this disease, the urine is made in small quantities, the thirst is great, and the breathing quick and laborious. This is in consequence of the fluid having taken up a portion of the cavity of the abdomen, and the lungs having become pressed upon, and not left sufficient room to perform their natural functions. From the abdominal viscera, too, pressing upon the diaphragm, the flesh becomes wasted, as well as the adipose matter, which is frequently found floating in the fluid.

For this continuation of symptoms we cannot always rely on a cure; but the disease fortunately happens but seldom, and then it is frequently the sequel of some other disorder of the viscera. If the animal, however, has stamina sufficient, there is a probability of recovery. Diuretic medicines are the only means to rely on, combined with tonics; and we cannot recommend anything better than the prescription laid down for dropsy in the chest. If possible, give exercise, rub the legs well, and bandage with flannel. We have found a cure, if taken in time, effected by blistering all four legs; and where the blisters rise well, this is pretty certain of being the case.

WATER FARTY, OR DROPSY OF THE SKIN.

The proper name of this disease is anasarca; but we have kept to the name it is generally known by, and that because it most frequently happens with young horses, and consequently, not having left the hands of the agriculturist, who might be somewhat puzzled without the local name.
Water farcy is described as a species of dropsy, rising from a serous fluid being spread between the skin and flesh; or, rather, it is a general collection of lymph in the cellular system. It shows itself first by a swelling under the horse's belly. This tumefaction is soft and inelastic, and when pressed upon by the finger, retains its mark for some time. By degrees it ascends and occupies the trunk of the body and the neck; even the eyelids, face, and nostrils appear bloated; the lips are much swollen; also the legs and the sheath become greatly enlarged. When the disease arrives to this pitch, breathing becomes difficult, the urine small in quantities, and dark coloured; the bowels are costive, and perspiration much obstructed. A remarkable thirst, attended with emaciation of the whole body, takes place; and to these symptoms may be added, a dull heavy appearance, and sometimes a cough.

In some cases the water oozes out through the pores of the skin; and the hair, which is, during the spring and the fall, rather longer than at other periods, becomes covered with the fluid thus effused. This disease may be brought on by all the causes which produce the last-named; but here we should say that debility is the chief cause. It is very frequent in the spring and the fall of the year, when horses are weak from moulting. When the disease is partial, it is not so difficult to cure as when it has become general. In treating for it, we must proceed to rouse the system by giving tonics, the most successful of which will be found in the following:

- Cantharides . . . 1 drachm.
- Sulphate of Iron . . . 2 oz.
- Sulphate of Copper . . . 2 do.
- Gentian . . . 4 do.
- Mustard . . . 3 do.
- Ginger . . . 3 do.
- Mix, and form into a mass with soft soap

Divide into twenty-four balls, and give one every morning.

If the swellings have become considerable, puncture them with a middle-sized phleme, or lancet, in several places, and allow the fluid to evacuate.

Great care must be taken to keep the horse warm. He must be clothed well, and well dressed morning and night; by which means the exhalants of the skin will be opened, and the animal greatly relieved. Attention must also be paid to his feeding, and the most nutritious kinds of food given him; oats, with beans, malt, and occasionally a few carrots. When the weather will permit, let him have exercise, with his clothing on. This will determine blood to the skin, and give him great relief; always remembering to put on him, after he has been dressed, a dry cloth. Do not forget to bandage his legs well with new flannel bandages. If he should not be in the debilitated state described, give him, in addition to the medicine prescribed, two or three times a week, at night-time—

- Aloes, Cape . . . 12 drachms.
- Nitre . . . 12 do.
- Resin . . . 12 do.

Mix, and divide into six balls.

**SWELLED LEGS.**

Swelled legs is a very prevalent disease of the horse, principally affecting the hind, or only one of the hind legs, although the fore are not exempt from the affection. It arises from various causes; but the one we have now to speak of, is occasioned by a deposition of fluid in the cellular membrane of the limbs—commonly in their lower parts, below the knee to the hoof. If the disease is suffered to increase, the skin cracks, and ultimately discharges pus, and then the complaint falls under the head "Grease," which is treated of in its proper place.

Swelled legs may be brought on by poverty, or wet straw-yards, especially where the animal has not been fed well, but kept on the outsides of hay-stacks, or that musty bad hay with which the farmer can do nothing else.

The complaint may supervene on other long-protracted diseases, and any of the above causes may produce it. Bad grooming will also bring it on; and the disease is very painful, and at times occasions lameness, and gives a great deal of trouble.

In all the foregoing stages, it is not difficult to restore the patient; for it is evident that the disease has arisen from the debility of the absorbents to take up the effused fluid, and return it into the system. In treating for it, therefore, we must employ tonic medicines to arouse them to a new action. Bleeding is not

</tbody>
</table>

Form into a mass with soft soap.

Divide into six balls, and give one every morning. Let the horse’s legs be well rubbed and bandaged. Give him gentle exercise once or twice a day; and these things being attended to, with good grooming and nutritious diet, as sweet oats, with a little chaff and bran, and occasionally a few carrots and speared barley, will restore him. Avoid, of all things, giving beans, as, when a horse comes from grass, or the straw-yard, and beans immediately given to him to force him, as it is called, the heels generally, after swelling, become cracked. This leads us to consider those other causes which occasion swelled legs, as heated and foul atmosphere, standing long in dung and urine, living high in the stable, and having little or no work. In coach-horses in particular, where their journeys do not exceed eight or ten miles a day, which are generally performed in an hour, or a trifle of time more, the disease is brought on by their standing in the stable twenty-three hours out of the twenty-four. Horses coming into hot stables with their heels wet from having been in water, and not immediately attended to—in most of these cases local debility is the cause; but we should not say general debility; because it occurs to horses high fed and exercised, as well as to plethoric animals, which sometimes are neglected. In treating for swelled legs in plethoric horses, bleeding will be highly necessary, with a course of physic—according to strength and constitution—of the purging-balls. After this, administer a dozen of diuretic balls, as prescribed in the list of medicines at the end of this work; and proceed as recommended in the article Condition, to which we beg to refer the reader; and which will be found to contain all the directions necessary.

CHAPTER XXII.

DIABETES; BLOODY URINE; STRANGUARY; URINARY ORGANS.

DIABETES, OR PROFUSE STALING.

Diabetes is not frequently found in the horse; but as it is occasionally, it deserves notice. Its indications are great thirst, accompanied with a voracious appetite, gradual emaciation of the whole body, and a frequent discharge of urine, containing a large proportion of saccharine and other matter, voided even in a quantity exceeding that of the aliment or fluid introduced. These are the characteristics of this disease. But it is always much milder when symptomatic, than when it appears as a primary affection. It may be occasioned by the too frequent use of strong diuretic medicines, severe evacuations, or by anything that tends to produce an impoverished state of the blood, or general debility; such as bad hay, heated oats, or such as may have been long on their passage, either from the Baltic or Ireland.

It has, however, taken place, in many instances, without an obvious cause.

That which immediately gives rise to the disease, has always been considered as obscure, and various theories have been advanced to account for it. It has been usual to consider it as the effect of relaxation of the kidneys, or as depending on a general colliquation of the fluids. The liver has been thought, by some, to be its chief source; but this organ is hardly ever affected by it.

The primary seat of the disease, although not absolutely determined, is considered, by the majority of practitioners, to be dependent on a primary affection of the kidneys.

It sometimes comes on so slowly and imperceptibly, without any previous disorder, that it, now and then, attains to a considerable degree, and subsists long without being accompanied
by evident disarrangement in any particular part of the system. The intense thirst which always, and the voracious appetite which frequently attend it, being often the only remarkable symptoms. It, however, generally happens that a very considerable affection of the stomach precedes the coming on of the disease; and that in its progress, besides the symptoms already mentioned, there is great dryness and roughness of the coat.

Under a long continuance of the disease, the body becomes much emaciated; the legs swell, great debility arises, and the pulse is weak and small.

In some instances, the quantity of urine expelled is much greater than can be, by any means, accounted for from all sources united; and when subjected to analysis, it is found to contain a considerable quantity of saccharine matter.

On dissecting and examining the kidneys of horses which have fallen victims to this disease, they have invariably appeared to have been much affected. In some instances they have been found in a loose flabby state, much enlarged in size, and of a very pale colour. In others, they have appeared much more vascular than when in a healthy state, approaching pretty nearly to what takes place in inflammation. The bladder, in almost all cases, is found to contain a considerable quantity of muddy urine.

In treating for it, there have been a great variety of remedies proposed; but their success is generally precarious, or, at least, only temporary. Medicines determining blood to the skin, are good for it; therefore we recommend the following:

- Antimony . . . . . . . . 1 lb.
- Sulphur . . . . . . . . . 1 do.

Rub together in a mortar, and divide into two-ounce packets. Give one in the feed, morning and night; first making the feed slightly damp, that the powder may adhere to it.

If the horse should appear weak and much debilitated, give him one of the above powders in his feed every night, and the following the first thing in the morning:

- Opium . . . . . . . . ½ drachm.
- Catechu . . . . . . . . 3 do.
- Arsenic . . . . . . . . 10 grains.

Form into a ball with syrup of buckthorn.

In addition to this, give about a pint of fresh lime-water, with a horn, every mid-day. To make the lime-water, take of quick-lime, light and fresh-burnt, one pound; put it into an earthen vessel, and pour upon it two gallons of water; let it stand until the lime is settled, then pour off the clean water. It must be kept in bottles, well corked. Keep the horse warm, and well clothed, and give moderate exercise. Do not ride him, but lead him, the groom riding another. Great attention must be paid to his food. If it is at a time of the year when new hay can be got, give some to prevent him from being thirsty. Oats must not be given, but barley, speared, or wheat with it; but not much.

**BLOODY URINE.**

This is a disease generally caused by some injury done to the kidneys, in straining to draw heavy loads, or carrying heavy burdens. It may be caused by ulceration of the kidneys, produced by violent exercise, or bursting some of the smaller vessels or other urinary passages, or any causes that may occasion rupture of the capillary blood-vessels in those parts. If there is a sudden discharge of pure blood by the urinary passages, it comes from the kidneys; but if a small quantity of dark-coloured blood, whether it be mixed with purulent matter or not, it proceeds from the bladder.

In prescribing for a cure, avoid giving diuretics, for they are very hurtful; and endeavour to restore the parts to a healthy state as soon as possible. With a view to this desirable end, give the following:

- Catechu . . . . . . . . 3 drachms.
- Opium . . . . . . . . 1 do.
- Alum . . . . . . . . . 2 do.
- Aloe, Barbadoes . . . . 1 do.

Form into a ball with honey or treacle.

Give one morning and night.

Many persons apply hot sheep-skins to the loins, but we never saw much good effect arise from their application. On applying the following, however, great good will arise to the loins of the animal.

- Liquor of Ammonia . . . . 2 oz.
- Olive Oil . . . . . . . . . 2 do.

Rub this on the loins morning and night. Mix, and when applied, shake the bottle well. If the horse is in high condition, take three or
four quarts of blood from him, and keep him warm.

STRANGUARY, OR OBSTRUCTION OF URINE.

This disease consists of an obstruction, or temporary suppression of urine, and may arise from different causes; for, the parts appropriated to the secretion and excretion of urine are so numerous, that the exact cause of the disease becomes a matter of ambiguity and uncertainty, even to very good judges.

Strangury, sometimes, is a concomitant of inflammatory colic, and is then the effect of pressure from the indurated faces, or hardened dung, retained in the rectum. When it does not arise from this cause, it may proceed from inflammation of the kidneys themselves, from ulceration, spasms in any particular part, inflammation of the neck, or the bladder itself.

When it is the consequence of colic, and proceeds only from that cause, it may be considered merely symptomatic, and may be entirely subdued on its first appearance. The signs of the suppression are too palpable to be mistaken. The animal is in an almost perpetual position to stale, without effect—indicating, by action and attitude, the expectation of an unusual discharge; when, after frequent straining, the effort terminates in a groan of seeming disappointment. He does not, in general, appear in acute pain, but seems full in the flank, somewhat dejected, and, to a minute observer, appears not only conscious of his inability to stale, but as if supplicating assistance and relief.

The most certain means of affording relief is to abstract about three or four quarts of blood, which will relax the parts; then introduce the hand into the rectum, and remove all hardened dung. This operation—which, by the old farriers, is called back-raking—being done, throw up an emollient clyster, composed of—

| Thin Gruel | . . . 3 pints. |
| Common Salt | . . . 3 table-spoonfuls. |

Let this be injected moderately warm, and retained in the body as long as possible, by keeping the tail pressed down against the fundament. If the bleeding and clysters have not had the desired effect in a moderate time, repeat the clyster, and give—

| Camphor | . . . 2 drachms. |
| Nitre | . . . 1 oz. |

Form into a ball with treacle.

Administer as soon as possible.

These are safe, mild, and efficacious measures, and, in general, produce the desired effect, without any uneasy sensations. Repeat the remedies every four or five hours, until the object is gained.

Thus much for strangury occasioned by spasm, or inflammation of the neck of the bladder; but it may proceed from inflammation or ulceration of the kidneys, accompanied with a paralytic affection or palsy of the parts; in either of which, symptoms are frequently doubtful, and seldom certain. Circumstances may constantly vary in different subjects, so as to render the true seat of disease a matter of conjecture only.

The only symptoms to which some certainty may be attributed are the following:—If proceeding from spasm, on either part, there may be frequent periodical relaxations, which will permit the urine to flow in small quantities for a very short time, when it may as suddenly stop. In this case, the urine will be of its usual colour, or at times rather darker, as if not perfectly complete in its secretion from the blood. In such a case the treatment should be as just pointed out, but with the addition of repeating the bleeding.

Where the case originates in palsy, or ulceration of any of the above-named organs, fulfilling the functions of the evacuations, no great expectation of cure can be indulged in, especially if the case is really one of palsy, which approaches certain death, and which exhibits all the characteristics of the most dangerous species of disease.
CASTRATION, OR GELDING.

The operation of castrating a horse is by the removal of his testicles, when, in technical language, he becomes what is called a gelding. The operation is the cause of the loss, to a considerable degree, of that fiery disposition sometimes displayed in the entire animal, or stallion. The gelding is considered of so much more general use, that few entire horses are kept, except in the racing stud, or by individuals, to breed from.

The proper time for castrating colts, is when they are about twelve, or from that to eighteen months old; but we have known both testicles, even at that age, not having descended into the scrotum. When such is the case, the operation must be delayed a few months longer. Some breeders, according to the custom of their locality, will have their colts cut when they are only about three months old; but, for all general purposes, we should recommend that colts should not be cut earlier than at twelve months. By this time they are better formed, and it is at a time when they cannot be used for any kind of work.

In Yorkshire they do not cut until the animals are three or four years old; hence the high breed of coach-horses in that county. Breeders there work them until they are nearly four or more years old, then castrate and bring them out at five years fit for the dealer; and, with the exception of cart-horses, they are the most valuable kind to breed from.

There is a great difference in castrating young colts and old horses—the former requiring no preparatory means to be employed, in consequence of their having been continually at grass. Not so, however, with old horses, which should be bled, and have a dose of physic, and be fed on bran mashers for a week before the operation takes place.

In effecting the operation, the mode of proceeding is to have the horse led out on to some soft straw or loose manure, then the hobbles put on, and the animal cast on his left side. The off hind leg should be secured with the side line, passed through a web collar buckled round the neck, and the line taken round the heel, and again through the collar. Before the operation is commenced, everything should be made perfectly and securely fast, that there may be no possibility of its giving way. Having everything in readiness—such as the smallest scalpel, the clamps armed with fresh tow, and a curved needle armed with fine pack-thread, in case of accident—take one of the sacs of the scrotum firmly in the left hand; then having the scalpel in the right, make a section in the skin in the most depending part of the bag, through the integuments, and of sufficient length for the testicle to protrude. Having accomplished this, lay down the scalpel, grasp the protruded testicle with the right hand, and gently draw back the scrotum with the other, so as to expose the spermatic cord, on which fasten the clamps sufficiently tight to prevent its slipping. All this being done, take the searing-iron, of a dark red heat, and saw the testicle off. We say saw, because if a saw-like motion is made, the end of the cord becomes cerated, and then requires but little more from the iron. Although in all cases it is necessary to touch the end of the cord again before loosening the clamps, to prevent bleeding, it is easily accomplished, provided due care is used. The clamps may now be gradually loosened; and if blood does not appear, proceed with the other in the same way. Should a little blood escape from the first orifice, do not feel alarmed, for it may be only from the struggling of the horse, which may be permitted now to get up, and let him be placed for a few days in a barn or outhouse. When the horse has been housed, give a diuretic alternative ball, composed of the subjoined ingredients:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cape Aloes</td>
<td>3 drachms</td>
</tr>
<tr>
<td>Resin</td>
<td>2 do.</td>
</tr>
</tbody>
</table>

Form into a ball with soft soap.

Continue the feed of bran mashers for three or four days, then turn him out.

We have never found this simple method to
fail, if proper care were taken; although it is a matter of wonder to us that many horses do not die, from the rough brutal manner in which the operation is performed in some counties. Some veterinarians will not perform the operation at all, as it requires all the skill of the surgeon.

Whilst serving in India, there was a case in which we were consulted, the subject of which was a beautiful chestnut horse. Although he was perfectly quiet and docile, the serotum had become so much enlarged in one of the sacs, that it hung down within a few inches of the hock of the animal. On examining this, the testicle was found remarkably small; but it contained a considerable quantity of fluid, which proved the fact that the horse was affected with hydrocele. The fluid could readily have been extracted; but fearing the bag might fill again, it was determined to perform an operation. Accordingly, on cutting through the tunics of the serotum, at least three quarts of yellowish fluid escaped. At this time it was difficult to retain hold of the testicle, from the considerable enlargement of the serotum. However, this was done, and the clams put well on; but not being content with doing well, the testicle was immediately removed with a scalpel, leaving the cord only within the clams. With the horse's struggles, and the cremaster muscle being on the stretch, he easily withdrew it from between that instrument, when the cord of course receded into the sac, and bleeding commenced most furiously. A straight needle was then taken, and the Glover's suture introduced, when the serotum filled with blood to a tremendous extent. The horse was then ordered to be kept quiet by himself, and six drachms of aloes given him, with bran mashes and hay. On the following day, the serotum was immensely large. Some warm water and a sponge was then procured, and the stitches begun to be cut. When this was done, it was found that three parts of a common stable-pailful of coagulated blood came tumbling down through the orifice made for the escape of the testicle. The serotum was now well syringed with warm water, into which about two ounces of chloride of lime had been put, until all appeared safe, and no discharge of blood whatever was seen. The serotum was dressed in this manner for three or four days internally, and regularly bathed with warm water outwardly, and around the sheath, three times a day. In three days over a month the horse was fit to be ridden.

The clams used in India are made from a round piece of wood about the size of the handle of a sweeping-broom, and are about five inches long. They are slit down the middle; so that they have two flat sides, with a groove about the size of a goose-quill up the middle. This groove is filled with corrosive sublimate, one drachm, and hog's Laird sufficient to form an ointment. They are, before placing on the cord, tied together at one end, then at the other pressed together with pincers and tied at the other: these are taken off on the morrow after the operation.

In performing the operation of castration, there are cautions required, and those of moment; and although the operation is mainly performed by ignorant men, who are called cutters or gelders, and, to all appearance, things go on as they should do; yet if any alteration for the worse takes place, these men do not understand what to do. It therefore behoves every man who undertakes the operation, to be well informed, not only of the parts involved in it, but their means of cure.

The greatest enemy the operator has to contend with, is inflammation of the parts. Should this take place, and the horse walk stiff on his hind legs, moving with a straddling gait—especially if he be an old one—the parts should be well bathed with warm water three or four times a day, and each time wiped thoroughly dry; then the enlarged serotum and sheath should be rubbed all over with good digestive ointment, some of which may be introduced into the sac, which will promote a discharge. Give the ball, as recommended before, every second day, until the swelling goes done.

The food must be regulated according to the age or size of the horse; but much corn must not be given him; bran mashes, green food, &c., are the best. To old animals, if attacked with swellings after the operation, a dose of physic must be given; and they should be bled. All the other applications will be needful to be attended to, precisely in the same manner as directed for young horses.
Lock-jaw not unfrequently supervenes on this operation in India, in consequence of the injury the nerve sustains, from the operator pulling at the testicle too forcibly, as already described.

HERNIA, OR RUPTURE.

Hernia, or rupture, is the displacement of a portion of the abdominal contents, from the cavity outwards, by some of the natural, or by some artificial openings. The intestines are by far the most common of the abdominal viscera. When such displacement occurs through an opening, and the protruded part can be readily returned, it is considered as reducible hernia. If, on the other hand, the opening is too small, of course it becomes irreducible. If the mouth of the sac around the intestine constricts, and produces inflammation of the gut, it then forms what is called strangulated hernia, and sometimes proves fatal, unless relief be promptly obtained.

From the position of the horse, stallions are frequently affected with scrotal hernia, from the scrotal cavity remaining open to the abdomen, and the intestine descending; but this is not the case with geldings, for the absorption which takes place after castration, almost prevents the possibility of scrotal hernia. In India, scrotal hernias are almost of daily occurrence, especially with horses which have violent action to perform, and are of a loose weak nature. Castration is not general in India; and the relaxing state of the climate may be considered to be the principal cause of this, as the operation is attended, not only with inconvenience, but great danger.

Omental hernia is exceedingly common in the East, where the operation of castration having been performed on a horse, the omentum protrudes of itself. The clams were put on, and the finger introduced into the sac, which, as far as it could be felt, was ripped off. The horse did well afterwards. Accidents, violent exertion, kicks, gores from neat cattle, may produce ventral hernia in any part of the cavity, and they will form a pouch or sac.

Horses may die from strangulated hernia; the death of which may be attributed to simple enterites, or any other cause. There was, in Devonport, a case of a black horse, which, on being brought into stable, evinced symptoms of enterites. He was bled to about six quarts; ordered gruel with Clysters, as if for enterites. Some hours afterwards it was found that the horse was not better. Counter-irritation was then prescribed, but to no effect. The horse died soon afterwards; and on opening him, a strong ligamentous cord, as thick as a man’s finger, was found inserted into the peritoneum, and continued up to the mesentery, into which it was equally firmly inserted. Now, by some violent exertion in going on the roads of Cornwall, where the horse was worked, the intestines had been thrown over this cord, and could not replace themselves. Strangulation was the consequence, clearly showing that violent exertions produce the disease.—To return, however, to our subject.

Most cases of reducible hernia, originating in accident to the walls of the abdomen, can only be supported by a bandage; the great force of the abdominal muscles, and our inability to keep the animal perfectly still while the parts unite, preventing their permanent reduction.

With scrotal hernia, however, we have a much greater advantage; and although the temporary reduction of the gut may be commonly affected by the application of the tectis, or by pressure, we have performed this operation when the accident never occurred again.

The symptoms which indicate scrotal hernia appear in some of the actions of the animal. He paws continually; lies down, and as frequently gets up; sweats profusely about his loins and quarters; sometimes takes a roll; but this appears to be done with such difficulty, that after immediately doing so, he will jump up so suddenly, that it is difficult to get out of his way. If the horse is an entire—for we have heard writers talk of scrotal hernia in geldings, although an instance never came under our notice—examine well the scrotum, in reference to its fulness and tenuity. Being satisfied on this point, have the horse’s four legs secured, and drawn by a rope until he completely lies on his back. This being done, endeavour to return the gut, by taking hold of the scrotum of the diseased side, and pressing it back through the fore finger and thumb. Should this not be readily accomplished, recourse must be had to the operation for hernia. When this is the case, take the diseased sac into the left hand.
lightly; then, instead of cutting at the most pendulous part of the sac, as in castration, cautiously cut into the sac near the seam or pubis, running between the sacs of the scrotum. Next take the scalpel, and divide the integuments carefully, until the contents of the sac can be felt with the finger. The opening made should be so small as only to admit the point of the fore finger. If the sac should be large or dilated, first make an incision on the side, that the fore finger may be introduced as far as possible; then a second cut should be made, allowing the finger to be the director. This being accomplished, introduce the finger into the abdomen, and feel for the abdominal ring. When this has been accomplished, take a history, and run it down by your finger, and partially cut through the ring, keeping the edge of the history bearing forward and upward. Should you succeed in reducing the hernia at first, the object is gained; but if not, you may cautiously try again, and divide the ring, should such be required. Immediately castrate the horse on that side. Give a gentle dose of medicine and soft food, as bran mashes, &c.

CHAPTER XXIV.

STRAINS.—STRAINS IN GENERAL; IN THE SHOULDER; BACK SINEWS; OVER-STEPPING; BREAKING-DOWN; RUPTURE OF THE BACK SINEW; STRAIN OF THE FETLOCK JOINT; COFFIN JOINT; ROUND BONE; STIFLE JOINT; ON CURB.

STRAINS IN GENERAL.

Strains are of two kinds; the one originating in the ligamentary parts, by which the different joints are preserved in contact; the other, in a relaxation of the muscles or tendons, or in a rupture of any of the membranes covering or adhering to such tendons, the purposes of which are the direct office of motion. Hence it is, that the farrier and the groom are so frequently at a loss for their definition of any particular lameness, fixing by conjecture upon any part, and attributing it to any cause but the right one. In giving their judgments, of course, they are seldom directed by any mental information, having little or no conception or scientific knowledge of the structure of parts, their purposes or appropriations.

The elastic part of a tendon or sinew, is that which is the muscular, of which, in fact, the tendon is a continuation only, with this difference, that the tendon is made by nature to occupy a much smaller space than the muscle; for it would destroy the symmetry of the animal if the muscles of the fore leg were to extend down to the heel, instead of that fine uniform make which the tendon gives, especially to the race-horse. The tendon is not of that elastic nature that some writers have described, but it is in the muscular end where the elasticity exists. This, at first sight, may appear strange, for the injury takes place in the tendon, and not in the muscle; and for this reason, the non-elasticity of the tendon and its sheath will rather submit to rupture, from want of the elastic quality. These tendons, or sinews, are strong substances, composed of innumerable threads or fibres, possessing the properties of extension and contraction to a certain degree, beyond which their flexibility cannot be extended without palpable injury and certain lameness; for by overstraining their elastic quality, small as it is, rupture is the consequence, accompanied with lameness in proportion to the injury sustained.

To render this idea as clear as possible, let us suppose that a horse is going at his best pace on the trot, and in so doing his toe covers a prominence, or the edge of one. In such a case the heel has no support; and the consequence is, an extension of the tendons, or a rupture of the same; by which means part of nature's work is destroyed, and what is termed
THE HORSE, AND

When the horse has continued in the stable, under the treatment mentioned, for at least a fortnight, he should, if in the winter-time, have his liberty in a loose box, bay of a barn, or large stable, where he will, by a natural attention to his own ease and safety—unless hurried, driven, or disturbed, which should by all means be prevented—sufficiently guard the injured parts. On the contrary, if in the summer, he should be turned into a paddock or pasture, alone, at a distance from other animals, where he cannot, by their neighings, be excited to any exertion of spirit or extravagance that may occasion a relapse. In either case, if the enlargement of the part does not subside, and the lameness bears no visible marks of amendment so soon as may be reasonably expected, take him up, and apply a liquid blister, composed of the following ingredients:

Mild Liquid Blister.

Cantharides, powdered . . . 4 drachms.
Vinegar . . . . . . 4 oz.
Mix well together.

This must be gradually rubbed over the whole part for at least half-an-hour, letting it, if possible, be entirely absorbed around the seat of pain; then apply the bandage as before described, and shorten the halter, to prevent the horse from gnawing the part. At the expiration of three or four days, he may either be turned out, or put into a loose box, as the time of year may serve; but let the time of year be what it may, a loose box is preferable to anything. When he is first brought into use, let his work or exercise be gentle, for fear of a relapse. If this should occur from some accident or misadventure, the following lotion must be applied to the affected part:

The best Vinegar, or Verjuice . . . 1 quart.
Common Salt . . . . . . 4 oz.
Rub the parts well with this twice a day.

By pursuing this mode of treatment, we have seen the complete cure of many, without the necessity of firing, which is in general by far too hastily adopted, and hurried on by the frequently unnecessary anxiety of the farrier. With all kinds of strains, however, the animal must have rest; and to this alone, nine times out of ten, the cure is to be attributed. Even
after firing, in extreme cases, turning out, and taking the horse up sound, the cure or soundness is rather to be assigned to the rest than the firing.

Strains in the ligamentary parts are in general occasioned by sudden jerks, short turns, or they may arise from the limbs sinking in deep ground, and the exertions which have to be made to get them extricated. The ligamentary parts being situated at the junction of bones, and, in some cases, covered with muscles and soft parts, no great expectation of relief can be formed from the efficacy of external application, when the seat of pain is unluckily so remote from the surface. We will now, however, enter upon a more especial description of strains, and their mode of treatment, when they occur in particular parts of the anatomical structure.

**STRAIN IN THE SHOULDER.**

Strain in the shoulder was formerly called chest, or body founder. Where there is strain in the shoulder, there cannot be the slightest mistake in discovering it, for the horse, in his pace, makes a circuitous or rotary motion of the leg that is affected, and drags his toe on the ground, in endeavouring to bring it forward. He also, if we may be allowed the term, appears to hutch up that side altogether, in endeavouring to walk.

These strains are frequently the consequence of a side wrench, or slip, by which the fore legs become so widely separated, that the muscles are stretched to an unnatural extent, or, in some cases, are actually ruptured; the greatest pain being evinced. The ligamentous attachment also participates in the injury, as the muscles of these parts are of themselves of a peculiarly delicate and tender nature, so as easily to become ruptured. Shoulder strains do not frequently occur; though grooms and farriers, and other persons connected with horses, are often led, from habit, to attribute to them every lameness they do not understand, and the seat of which does not make itself evident to the untutored senses; for, on viewing a horse in front, the muscles of one shoulder will sometimes appear wasted. Though this be so evident, it requires more than usual explanation to make even intelligent persons believe that the evil did not originate where it appears to have done.

In all affections of the feet, where there is much pain and lameness, nine times out of ten, the lameness is placed on the shoulder, and this in consequence of persons not knowing the real seat of disease; for the horse will draw his fore legs closer together, when the spine of the blade-bone becomes prominent, and the whole substance seems lessened. The origin is from inaction, in which case muscles always diminish; added to which, the pain the animal is continually in, occasions him to give rest to the diseased limb.

It is very necessary, therefore, to be able accurately to distinguish shoulder strain; and if proper attention is paid to the rules before laid down, as to the action of the leg, there will be but little difficulty in at once pronouncing where the seat of lameness exists. When the horse is at rest, the limb is generally pushed forward, the animal scarcely daring to touch the ground with it, the toe only just resting on it, as we see when he seems to be in the act of lifting the leg. By these means it is easy to distinguish shoulder strain from diseases of the feet; for in those cases, the horse puts his foot straight out—what is called *pointing*—resting on the entire foot. These symptoms being so entirely different to affections of the feet, there can be no difficulty in determining between the two, especially if, in taking the leg off the ground, and extending it forward as much as possible, the muscles of the chest are at the same time pressed. This will at once determine, in the mind of a judge, the seat of lameness.

The seat of the lameness being discovered, we refer the reader to that portion of the work treating of *Strains in General*; and, as a remedy, we recommend the use of the liniment directed for strains.

Some people prefer what are called repellents, or cold applications; but these will be always found to fail, nothing answering so well as a remedy that will promote the action of the absorbents, and, at the same time, act as a counter-irritant. Should the injury to the parts occasion a degree of fever, let blood be taken from the jugular vein, according to the size and strength of the animal. Apply then the tar liniment; but do not apply a common blister,
whether the lameness arise from a ligamentous strain of the shoulder, or from the muscles of the chest; for, at best, either blemish or eschar will be produced. As a mild application in the form of a blister, we recommend the mild liquid blister in the article on Strains in General. Apply as directed under the head of that article, rubbing on the affected part, morning and night, until the swelling and inflammation will not allow this to be continued longer. Be not alarmed at this, but wait for two or three days, and the swelling will subside, when the application should be repeated, until the same effects again prevent the application. In this way a mild inflammation should be kept up for a week or ten days, in accordance with the abatement of the disease. It is very seldom necessary to continue the application after the second time, the disease generally yielding by that time to its use. This will be found a much more eligible mode of practice than the common blister ointment.

In addition to the above remedies, the alterative medicine, as before directed, must not be forgotten to be given, as it will not only keep the system cool, but will promote the absorption of any extravasated fluid that may have taken place in consequence of the injury.

There is one thing in strain of the shoulder, which must in no wise be lost sight of; and that is rest. We have already mentioned this in the article on Strains in General; but it cannot be too deeply impressed on the minds of the keepers of horses; for, though the lameness may disappear on bringing the animal first to work, in nine cases out of ten, the lameness will return on the least exertion. We would, therefore, again recommend at least a month or two in a loose box, or in a field where he can be quiet, previous to using him, though he may not appear lame.

Horses sometimes, from other horses, receive kicks, which affect the shoulder, and occasion considerable lameness, when there is no strain whatever. When such is the case, bathe the shoulder well with warm water; after which, wipe completely dry, and apply the tar liniment, as directed before. Insert a rowel in the chest, which will be preferable to bleeding in the plate vein.

---

STRAIN OR CLAP IN THE BACK SINEWS.

A strain, or clap in the back sinews, is not thought so much of by some writers as it really deserves; but it rarely occurs, that a horse when once strained in his back sinews, or tendons, or their sheaths, ever becomes able to perform much hard work. Still, we have known both race-horses and hunters to be capable of work after an accident of this kind; but not frequently so. However, as the disease is one which often occurs, we must do our best to alleviate the acuteness of the pain under which the animal labours when visited by such an affliction.

Referring to the article on Strains in General, it is there stated, that laceration of some of the ligamentous fibres may occasion the affection; still it is, however, more generally confined to a distension of those parts, and of the sheaths of the tendons beyond their structural capacity; although there is little reason to doubt that the tendons themselves are also sometimes acted on. This disease may occur to the hind legs, as well as to the fore ones; but we never saw it attack the hind legs. It may, however, be brought on in the fore legs by treading on anything suddenly; such as in downward leaps, in attempting to recover a false step, or treading unevenly on any hard or prominent substance. It is also occasioned frequently by lowering the heels too much, or too suddenly, by which the tendons are brought too much into action. When the injury has occurred, inflammation, with all its attendants of heat, swelling, pain, and lameness, and, in all probability, an incapability of extending the limb, come on. The effusion from the ruptured vessels may be absorbed with proper treatment; but if coagulate lymph is once formed, it will either be accomplished, or, perhaps, not at all. More especially this will be the case if the lymph should be thrown out between the tendon and its sheath, where it is not so readily absorbed, and where it may form callosities around the back sinews, which so frequently follow these accidents, and, by their enlargement, obstruct the motion of the limbs, which is felt in a great degree after exertion, and is shown in a particular manner at first starting. Having become warm, however, the lameness apparently leaves him; and it is
then said by persons who have to drive such a horse, "Oh! it will go off as he becomes warm;" not at all reflecting on the sufferings of the poor animal. The action of exercise, occasioning friction, produces warmth, stimulates the absorbents to take up the fluid from the mouth of the ruptured vessels, and consequently, for a time, or when the horse is in action, the swelling and lameness either partially or wholly disappear. From these circumstances, the advantage of hand-rubbing and the flannel bandage will at once be perceived.

For the treatment of strain in the back sinews, we must refer our readers to where we have treated of strains in general. Here, however, we may add, that on the first discovery of the accident, the shoes should be taken off, and the heels turned up about half an inch. This will greatly relieve the pain under which the animal may be labouring. Bleed in the plate vein; next bathe the leg in warm water, and use the "tar liniment," as before directed. If symptomatic fever should come on, use the alternative medicine, and a cooling diet, as bran mashes, and a few carrots, now and then; corn need not be so plentifully given.

Should the repetition of the liquid blister not be successful, have recourse to firing; and, with care, this operation may be performed not only with neatness, but as scarcely to be seen. We have, in severe cases, been obliged to fire twice, which has proved successful; still we do not recommend firing until all other remedies fail; and previous to which, we would advise the application of mercurial poultice; or, perhaps, what may be more convenient, mercurial ointment. Take of

Mercurial Ointment (strong) . . . 2 oz.
Rub a portion of this on the diseased part, first warming it to make it pliable, morning and night, for three days; then, waiting one day, apply the liquid blister as before described. Put a cradle on the neck of the horse, to prevent his biting the parts; and if he appears irritable, tie him up to the rack.

OVER-STEPPING.

Over-stepping, or, as it is called by some, over-reaching, arises from a peculiar length of action which the hind legs have to the fore ones, in consequence of which the fore legs cannot get out of the way of the hind ones. When this occurs it is very liable to injure the fore legs, and, in some cases, so much so, as to throw the horse down.

Over-stepping sometimes happens from the toe of the hind foot being too long, and not squared off properly. It may also occur from bad riding, in pulling up short, or by a horse galloping with the wrong leg first, which altogether alters his gait, so much so as to be uncomfortable to both "man and beast." The consequence is, that in the attempt to get himself into the proper mode of gallop, he will strike his hind foot against his fore leg; and, if he does not come down, will lacerate the leg, sometimes in a terrible manner. Whenever the wound is such as to leave a flap of skin, whether it is upwards or downwards, or sideways, it should immediately be cut off as close as possible, as a reunion of the parts can never take place; and by leaving the flap, and attempting to effect the reunion of the parts, there would be a thickening and a greater blemish, and its removal would be found necessary at last.

Though we have introduced this affection in the chapter on Strains, it probably would have been better in the chapter on Wounds; but it so frequently happens that the tendons become injured by the blow inflicted, that we may be pardoned for including it with diseases of the tendons.

In treating for over-stepping, poulticing will be highly advisable; and nothing can be better than a warm bran poultice, which should be applied until the inflammation is subdued, always recollecting to bathe the leg in hot water. When the inflammation is removed, use the following two or three times a day:—

Hog's Lard . . . . . . 2 oz.
Alum, finely powdered . . . 3 do.
Salpate of Zinc . . . . . ½ do.

Work these ingredients well together in a mortar, and apply as above. A cure may be expected in a few days.

BREAKING-DOWN.

Breaking-down is a term so generally understood, that it is familiar to all sportsmen and horsemen, though, in medical language, it is called "rupture of the suspensory ligaments." This is an accident that most frequently occurs
to young horses, either in breaking or training, and more particularly so to the race-horse than to any other. The severe training the race-horse has to undergo at the present day, makes him exceedingly liable to rupture the suspensory ligament; as the fixed point of it being immediately under the knee, and then inserted into the heads of the sesamoid bones, puts this ligament so much upon the stretch, that at every bound the horse takes, there is no wonder it becomes ruptured; especially when we take into consideration the age at which horses are brought to the course nowadays, to what they formerly were, and also the pace at which they go. Though the distance may be short, it is the pace that kills.

It has been supposed by some, that this accident has arisen from a rupture in the flexor tendon; and we have known, after the operation of neurotomy, the flexor tendon to be partially divided, and the horse go as if rupture of the suspensory ligaments had taken place. The limb, in such a case, betrays the greatest weakness, and the fetlock is almost brought to the ground.

A perfect cure is seldom obtained; but there have been cases where horses have broken down, and been able to race again, and become valuable. We could relate several instances of the sort; but we will rather proceed to the cure of breaking-down.

The first thing to be done is to bathe the leg well in hot water; then send for the shoeing smith, and direct him to put on a high-heeled shoe, in order to relieve the parts. The horse, in consequence of the pain he endures, will be anxious to eat. Therefore give him cold bran mashes, and the alternative ball, as prescribed in "Strains in General." This being done, apply the tar liniment, as before directed, well bandaging the leg, from the knee to the fetlock joint, or a little below it. If, after the trial of this application for about a fortnight, it does not succeed, proceed to firing; for the mode of performing which, see Plate.

RUPTURE OF THE BACK SINEW.

This is an injury that does not frequently occur, though the former injury is in many instances mistaken for it; but they are not the same cases. Though the membranes and the small vessels supplying them with blood, frequently become ruptured, and occasion great lameness, still the substance of the sinew rarely is ruptured. In such a case we should recommend the same treatment as in the preceding, which will be always found the best; and if necessity requires it, recourse to firing must be had. Here rest will be a grand auxiliary, and in a loose box, if possible; for, from the frequent excitements which a horse has in the field, he is apt to forget his lameness for the time, and commence galloping about, much to his detriment, and to the retardment of his cure. Slinging has been recommended in cases of this injury; but the great difficulty in keeping horses suspended is such, that we never saw any good arise from it.

STRAIN OF THE FETLOCK JOINT.

This arises from injury done to the ligamentous and tendinous connexion of these parts, either from long-continued exertion, or from the effects of more momentary, but violent efforts; such as are made in leaping, or slinging on unequal or stony ground; by which means the leg may be turned aside, similar to sprain of the ankle of the human subject. Another cause is, that some horses, let them be going at whatever pace they may, occasionally have a peculiar drop behind. This principally arises from debility, or from the animal having travelled too far, and exhaustion taken place. Though this at first seems but trifling, it occasions great pain to the horse. Here the tar liniment will be found of great benefit, seldom failing to remove the lameness in a few days. In all these cases, the warm-water bath and the flannel bandage should be used.

STRAIN IN THE COFFIN JOINT.

Strain in the coffin, as it is termed by farriers and grooms, is not so common a case as is generally thought to exist; for its being confined partially to the hoof, prevents its being subject to those strains to which other joints are liable.

When a horse becomes lame, an attentive examination of the feet and coronet should not escape the attentive observer; but if heat is found about the coronet, this is not to be taken for the disease.
The lateral ligaments uniting the small pastern bone to the coffin bone, being the seat of disease, not unfrequently ossific matter is secreted, arising from the inflammation that proceeds from the strain. To ascertain if this be the case, pass the hand carefully down the fetlock-joint, until it comes to two little prominences. Just above these is the junction or union of the large and small pastern bones; and where this disease exists, considerable heat will be felt; and on pressure, the horse will exhibit considerable pain and uneasiness.

In treating for this kind of strain, bleed in the pastern vein, or, probably, what will be more convenient, take blood from the foot; previous to which, immerse the foot in hot water for at least half-an-hour, changing the water as it becomes cool. After this, apply the mild blister ointment, as directed in the list of medicines. Should this prove ineffectual, have recourse to firing.

**STRAIN OF THE ROUND BONE.**

The old farriers attribute lameness behind to strain in the round bone, or stifle, just as their fancy leads them to favour one or the other. However, sometimes the ligaments of this joint become injured by violence. A horse in a narrow stall, may injure himself, either by turning round, or by getting up, or lying down; and we have known some so much injured, that what with their exertions in getting up, and with the narrowness of the stall, they have considerably injured themselves in making an effort to rise. This injury has arisen from the ligaments of the articulation bone of the thigh with the pelvis becoming strained.

For the treatment here we must not employ either blister or setons, for the deep-seated situation of the injury prevents this mode of treatment being of much avail; and if the part is fired over, there is then a confirmed blenish. The best thing to do is to use

- Tartrate Emetic : : : 1 drachm.

Rub these well together, and apply to the parts affected, morning and night, until pimples arise; then desist. Apply a little hog's lard occasionally, to make the parts supple; and all will, in a short time, be right.

**STRAIN OF THE STIFLE-JOINT.**

Injury or strain of the stifle-joint frequently occurs from the horse slipping suddenly onwards, and causing the ligaments to become extended beyond their capacity. It may also arise from kicks or other injuries. In such cases the limb has a peculiar rotatory motion, being dragged after the animal with the greatest pain, and apparently even with a considerable effort to move at all. Sometimes the muscles of the thigh are the parts alone which are injured, and which produce the lameness.

For treatment, we recommend the "tar liniment," which we have always found to have the desired effect. Should this not succeed, try the mild liquid blister, set down in "Strains in General." Do not think of firing, as the blemish thereby incurred is a stain in the horse's character ever afterwards.

**ON CURB.**

This affection has been generally applied to a partial dislocation of the os calcis; but this is not the case, it being a rupture of the membranes of the sheath of the tendons just passing over the lower end of the metatarsal bones of the hock-joint, which sheath is placed there to strengthen the parts where the most considerable point of action in the hind extremity is required. Hence this affection arises so frequently from any sudden action; from leaps, or where the propelling motion is brought most into use; also rearing, or a sudden slip will produce it. It frequently makes its appearance unexpectedly from the above causes.

Curb may appear without lameness, from malformation of the hock, which is called sickled hocked, though no curb in reality exists. The lameness arising from curb is excessively painful to the horse, though some writers deny this; but any thereal rupture cannot possibly occur without giving great pain, as the animal cannot move without bringing the diseased parts into action.

For the cure of curb, the practice at the Royal Veterinary College, is to put on a high-heeled shoe, and bathe the hock frequently with cold water, or cold salt and water; but these applications seldom or ever succeed. When this is the case, a seton is passed over

251
the part, which has just as much effect as passing a seton down the fore leg, in order to remove this accident. For feed and medicine we refer to the article on "Strains in General," where all the required information will be found.

CHAPTER XXV.

INFLAMMATIONS.

The term inflammation is generally understood as expressing that state of a part in which it is painful, hot, and somewhat more turgid than it naturally is; such topical symptoms, when present in any considerable degree, or when they affect very sensitive parts, being attended with fever, or a general diseased action of the system.

The susceptibility of the body to inflammation is of two kinds—the one original, constituting a part of the animal economy, and beyond the reach of human investigation; the other acquired from the influence of the weather, sudden changes from hot to cold, and also from cold to hot stables, not well ventilated; blows, kicks, &c. The first kind of susceptibility cannot so well be diminished by art, as some animals are exceedingly liable to inflammatory attacks from their form; such as narrow-chested horses, or light chestnut ones. The second may be lessened by the mere avoidance of the particular causes upon which it depends.

Inflammation may, with great propriety, be divided into the healthy and the unhealthy. Of the first, there can be only one kind; of the second, there may be many, according to nature and situation, and kind of disease. It may also be divided into the acute and chronic. Healthy inflammation is generally quick in its progress, for which reason it must always rank as an acute species of the affection. Chronic inflammation is always accompanied with a diseased action, as exemplified in tumours, &c.

PRINCIPLES OF INFLAMMATION.

There is much foundation for believing that healthy inflammation is obedient to ordained principles, according to the tone of the constitution, or the structure or situation of the parts affected. The nature of the existing cause can have no share in modifying its appearance, whether its occasioned by the application of heat, or by violence done. Healthy inflammation is always the same in its nature, and all the influence is proportioned to the degree of violence accompanying these causes.

The observations of experience, as being the only solid basis of all medical as well as other knowledge, has informed the practitioner, that parts which, from their vicinity to the source of the circulation of blood, undergo inflammation more favourably, resist disease better than those parts which are more remote from the heart. The extremities are more prone to inflammation and disease in general, than parts nearer the heart; and when inflamed or cracked, they are longer in getting well. The circumstance of their being depending parts, which retards the return of blood through the veins, must also increase the backwardness of such parts in any salutary process.

Inflammation, when situated in highly organised and very vascular parts, is more disposed to take a prosperous course; and is much more reducible by art, than parts of an opposite texture. The nearer, also, such vascular parts are to the heart, the greater will be their tendency to do well in inflammation. Hence, inflammation of the skin, cellular substance, muscles, &c., more frequently ends favourably than the same affection of bones, tendons, ligaments, &c. It is also more manageable by surgery; for those parts which
are not what anatomists term vascular, seem to enjoy only inferior powers of life: and this explains the difficulty of removing any inflammatory action that may arise in the tendons of the leg, which, from their whiteness, are not very vascular.

But inflammation of vital parts, though these may be exceedingly vascular, cannot go on so favourably as in other parts of resembling structure, but of different functions; because the mutual operations of universal health depend so much upon the sound condition of such organs. The truth of this observation is illustrated in cases of inflammation of the stomach or lungs, &c.

In strong constitutions, inflammation always proceeds more propitiously than in weak ones; for where there is much strength, there is considerable irritability. In weak-constitutioned horses, the operations of inflammation are backward, notwithstanding the part in which it is seated may, comparatively speaking, possess considerable organisation and powers of life.

Inflammation, wherever situated, is always most violent on that side of the point of inflammation which is next to the external surface of the body; and this is particularly exemplified in gun-shot wounds. Suppose a ball were to pass into the thigh, to within an inch of the opposite side of the limb, we should not find that inflammation would be excited along the track of the ball, but on the side next the skin which had not been hurt. If a ball should pass quite through a limb, and carry into the wound a piece of the saddle clothing, lodging in the middle, equidistant from the two orifices—which is not unfrequently the case in cavalry regiments—the skin immediately over the extraneous body would inflame, if the passage of the ball were superficial.

We see three very remarkable effects follow the prevalence of inflammation—viz., adhesions of parts of the body to each other, the formation of pus, or suppuration, and ulceration; a process in which the lymphatics are more concerned than the blood-vessels. Hence the terms adhesive, suppulsive, and ulcerative inflammation.

All parts of the body, however, are not equally liable to each of the preceding consequences. In the cellular membrane, and in the circumscribed cavities—especially the cavity of the chest—the adhesive stage takes place more readily than in the others; suppuration may be said to follow next in order of frequency; and lastly, ulceration. Now, the ulcerative stage of inflammation most frequent in the horse, attacks the air-cells of the lungs, or the kidneys, but does not seem to affect, more than partially, any other mucous membranes. The supplicative inflammation comes on more readily than either the adhesive or the ulcerative stage. Adhesions, which originate from the slightest degree of inflammation, in other situations and structures, can only be produced by a violent kind in the above-mentioned parts. Ulceration is more frequently met with upon mucous surfaces than adhesive ones.

The cellular membrane appears to be much more susceptible of the adhesive inflammation than the adipose, or fatty cells, and much more readily passes into suppuration. Thus, we see the cellular substance, connecting muscles together, and the adipose membrane to the muscles, inflaming, suppuring, and the matter separating the muscles from their lateral connections, and even the fat from the muscles, while the latter substance and the skin are only highly inflamed. But it must be allowed, that in situations where fat abounds, we very frequently meet with abscesses. This is so much the case, that fat has been accounted a more frequent nidus for the collection of matter, than the cellular substance. We have spoken above of the inflammation of the fats; but this is not an expression strictly true. Fat has no vessels, or principle of life, or action of its own; consequently, we cannot suppose it can either inflame or suppurate.

We know that it is itself a secretion; and, when an abscess is formed in it, we understand that the mode of action in the vessels naturally destined to deposit fat, has been altered to that adapted to the formation of pus. When we speak of the fat being inflamed, we mean that the membranous cells in which it is contained, and by which it is secreted, are thus affected.

The deeply-situated parts of the body, more especially the vital ones, very readily admit of the adhesive stage of inflammation. The circumstance of deeply-seated parts not so readily
taking on the suppurative stage of inflammation, as the superficial ones do, is strikingly illustrated in cases of extraneous bodies; which, if deeply lodged, only produce the adhesive inflammation. By this process, a cyst is formed, in which they lie without any inconvenience; and they may even gradually change their situation without disturbing the parts through which they pass: but no sooner do these same bodies approach the skin, than abscesses immediately arise.

All inflammations, attendant with disease, partake of some specific quality, from which simple inflammation is entirely free.

When the constitution allows the true adhesive and suppurative stages to occur, it is to be regarded as the most healthy.

SYMPTOMS AND NATURE OF HEALTHY INFLAMMATION; PHLEGMON.

Swelling, heat, and pain are the principal symptoms of phlegmonous inflammation; and this term is usually applied to a circumscribed tumour. These are the first appearances observed in every case of phlegmon; and when they are slight, and the part affected is of no great extent, they have commonly very little, and sometimes no apparent, influence on the general system. But when they are more considerable, and the inflammation becomes extensive, the soft parts are more swelled than the harder ones.

Although all the symptoms of inflammation, such as swelling, throbbing, tension, may be less manifest when the affection is deeply situated, yet they certainly exist, as in poll-evil, fistulous withers, &c. Frequently, in horses dying of inflammation of the lungs, the air-cells of these organs are found crowded with a larger number of turgid blood-vessels than they have when in the healthy state. Coagulable lymph, and even blood, are extravasated in the substance of these viscera, which of course become heavier, and feel more solid.

The extravasation of coagulated lymph, which is one of the chief causes of the swelling, is also one of the most characteristic signs of phlegmonous inflammation. Common inflammation exists wherever the blood-vessels appear to be more numerous and enlarged than they are in a natural state, accompanied with an effusion of coagulating lymph, whether upon the surface of a membrane, or a bone, or in the interstices of the cellular substance, and attended with throbbing and acute pain in the part affected. Various causes produce inflammation.

REMOTE CAUSES.

The remote causes of inflammation are several in number, but very easy of comprehension, because only divisible into two general classes. The first includes all such agents as operate by their stimulative or chemical qualities—as, for instance, cantharides, large doses of aloes, heat, &c. The second class of causes are those which act mechanically; such as bruises, wounds, &c. After saying thus much, it seems quite unnecessary to give a detail of each particular remote cause.

One remote cause, however, and not the least singular, is cold; which appears to act in different ways. First, it may be applied in such a degree, and for such a length of time, as to destroy the vitality of the part directly, in which case sloughs are formed. In India this is a frequent occurrence with the horse and the native Indian. In the horse, it is called by the native barsatee, and is exceedingly troublesome to be healed. Likewise in the native, in the cold season, it is not uncommon for pieces to come out of the thighs (which are principally bare) as large as half-a-crown.

In the horse, from the troublesome tearing of the flies, it becomes exceedingly annoying to the surgeon. Secondly, it may be applied in a less degree, or for a shorter time; and afterwards a stimulant, such as heat, may be applied, which will excite inflammation. The production of inflammation by any agent, depends, in a great degree, upon the suddenness of the operation of the agent which excites it; for a quantity of stimulus, which, if suddenly applied, would produce inflammation, may be applied slowly with impunity. Hence, every slight stimulant will produce inflammation and sloughing, in parts which have been weakened by cold. Thirdly, a part sympathises very much with the contiguous ones. If a part is weakened by having its action reduced, and if then the debilitating cause is removed, the action of the part will be increased from sympathy with the neighbouring parts. But, as the action ought to be very little, the power
being small, inflammation must arise from the action being increased beyond the power. We ought, therefore, in this case, to diminish the action of the neighbouring parts, in order to prevent an extension to a part which cannot bear the effect of it without becoming diseased.

PROXIMATE CAUSE.

Numerous opinions have been entertained upon this subject; but almost every theory has been built upon the supposition of there being some kind of obstruction in the inflamed parts.

While the circulation of the blood was unknown, and the hypothetical notions of the power of the liver, in preparing and sending forth the fluid, continued to prevail, it is not astonishing that the theories of so many writers should be imperfect.

It was formerly supposed that the liver was the centre of the vascular system, from which the blood went forth by day to the extremities, and returned again by night. If, then, any pectoral matter irritated the liver, the blood was sent out more forcibly; and if, at the same time, any part of the body were weakened, or otherwise disposed to receive a greater quantity of fluid from the rest, then a swelling was produced by a flow of humours to this place. Fluxions, or flows of humour to a place might happen, either from weakness of the parts which allowed the humours to enter more abundantly, or from the place attracting the humours, in consequence of the application of heat, or other agents.

The ancient writers who suppose that the blood had very little motion, and that its course could easily be directed or changed, recommended heat to some part which was remote from a recent inflammation, by which they imagined that the current of blood was altered, and a revulsion made. A revulsion was also made by raising a tumour in some other part, or giving nature an opportunity of discharging the humours from distant parts, by applying blisters, &c. When blood was drawn from the vicinity of the fluxion, or congestion, the mode was called derivation, which only differed from revulsion in the distance to which the humour was drawn being less. Our present object is only to trace the leading doctrines which have at different times prevailed, as being the proximate cause of inflammation.

From the theories of fluxion and congestion, which were quite incompatible with the laws of circulation of the blood, we turn our attention to the doctrine of obstruction.

By some writers obstruction has been strongly advocated, attributing it to a viscosity of the blood, and also imagining it to occasion a resistance to the circulation in the part affected; hence, increasing it in the other vessels, proving an irritation to the heart, and augmenting the force or attraction of the blood in that part of the vessel which was behind the obstruction, causing heat and pain, and consequently an acrimonious state of the fluids, to be followed, in all probability, by gangrene.

The viscosity cannot be admitted as a proximate cause of inflammation, because we have no proof, say some authors, that this state ever exists; for, as they say, "Were a viscosity to occur, it would exist in the whole mass of blood alike, and could not be supposed to produce only a local disorder." This, however, is not true, for all parts are not so susceptible of taking disease as others; consequently, any poison producing inflammation that may have been taken into the system, may affect one part, and that only; and this from the susceptibility of the part.

As for the supposition of the co-operation of an acrimony of the fluids, the proportion of the saline matter of the blood has never been proved to be greater in this than in any other state of the body. Even were a general disorder of this kind to be admitted, no rational explanation of the proximate cause of local inflammation could be deduced from it.

According to the opinion of one of our best authors, inflammation is to be considered only as a disturbed state of parts which require to be restored to a natural mode of action. Inflammation in itself, therefore, is not to be considered as a disease, but as a salutary operation, the consequence either of some violence, or some disease. The same author further remarks, that the act of inflammation is to be considered as an increased action of the vessels; which action, at first, consists simply of an increase, or distension, beyond the natural size of these. This increase seems to depend on a diminution of the muscular power of the vessels; whilst, at the same time, the elastic power of the artery is to be dilated in the same
proportion. This is, therefore, something more than simply a common relaxation. The whole may be considered as a necessary operation of nature. Owing to this dilatation, there is a greater quantity of blood circulating in the part, which is in accordance with the common rules of the animal economy; for whenever a part has more to do than simply to support itself, the blood is there collected in a larger quantity; and nature never errs. The swelling is produced by an extravasation of coagulable lymph, with some serum; but the lymph differs from the common lymph, in consequence of passing through the inflamed vessels. It is this lymph which becomes the uniting medium of inflamed parts. Vessels shoot into it, and it has even the power of becoming vascular itself. The pain proceeds from spasm. When a part cannot be restored to health, after injury by inflammation alone, or by adhesion, then suppuration, as a preparatory step to the formation of granulations, and the restoration of the part, takes place.

An increased action of the vessels is now universally regarded as the proximate cause of inflammation. This opinion is greatly supported from a review of the several existing causes of the affection, which, being in general of an irritating nature, must, when applied to any living or sensitive parts, occasion a preternatural exertion of the vessels. The method of cure, as we shall presently show, tends also to confirm this doctrine with respect to the cause of inflammation.

SYMPTOMS OF INFLAMMATION FURTHER CONSIDERED.

The essential symptoms are swelling, heat, and pain.—Swelling.—This effect arises from several causes. First, from the increased quantity of blood in the vessels. Second, from the effusion of coagulable lymph and the deposition of a new matter. Third, from the interruption of the absorbents, or their incapacity to perform their office or functions.

Heat.—It was formerly imagined that heat was produced by the attraction of the red globules, of which blood is composed, against the sides of the vessels. Modern philosophy, however, teaches us, that a fluid may flow with the utmost velocity through a pipe, for a thousand years, without producing a single particle of

heat. The most commonly received opinion now is, that the production of animal heat depends on the different degrees of power which arterial and venous blood have to combine with caloric; whilst in the minute arteries, the blood is combined with certain substances. In consequence of this, its capacity is diminished, and heat is given out. When the venous blood, however, has been freed from such substances in the lungs, its capacity is increased, and the heat which is given out by the decomposition of the air which we inhale, is absorbed. These facts show that the augmented heat of inflammation arises from the increased velocity of the circulation in the part affected. More blood is transmitted into the minute arteries; the capacity of a greater quantity of this fluid for heat is of course necessarily increased, and more caloric extracted.

Pain.—This is observed to be the greatest during the diastole of the arteries. The affection is probably owing to the unnatural state of the nerves, and not to mere distension, as many have asserted. Were the latter cause a real one, the pain would be proportioned to it.

THE BLOOD IN INFLAMMATION.

Blood, when taken out of the living vessels, spontaneously separates into two distinct parts; the serum, and the claret-vessels. The latter is a compound substance, consisting chiefly of coagulating lymph and red globules, which are the heaviest ingredients in blood. Blood taken away from an animal affected with inflammation, is longer in congealing, and coagulates more firmly than under any other circumstances. Hence, the red globules not being so soon commingled with the lymph, descend by their gravity; and being more or less divested of the red colouring matter, they are, from their appearance, termed the buffy coat, or inflammatory crust. The firmer and more compact coagulation of the lymph presses out an unusual quantity of serum from it, and the surface of the sly blood is often formed into a hollow, the edges being drawn inward. These changes are, in some cases, a more infallible sign of the existence of inflammation, than the state of the pulse itself. At the same time, they are probably only a criterion of some unusual operation going on in the system. In peritoneal inflammation, the horse, sometimes, seems to
be in the most feeble state; and the pulse, abstractedly considered, would then rather induce the practitioner to employ tonics and stimulants, than evacuations; but should the continuance or exasperations of the disorder, or any other indication, lead to the use of the lancet, then the bulby coat and the concave surface of the blood, clear away all doubt concerning the existence of inflammation.

**TERMINATION OF INFLAMMATION.**

_Inflammation_ is said to have three different terminations; or, in other language, after it has continued a certain time, it either subsides entirely, induces a disposition in the vessels to form pus, or completely destroys the vitality of the part.

When the inflammation is to end in the first-named manner, which is the most favourable, the pain becomes less, the swelling abates, and every other symptom gradually disappears, till at last, the part is wholly restored to its natural size. There is no formation of pus, or any permanent injury of structure. This termination of inflammation is termed _resolution_. It is fortunately the most common, as well as the most desirable manner in which the affection should end.

If, however, notwithstanding the application of the usual remedies, the several symptoms of heat, pain, &c., instead of diminishing, rather increase, and the tumour gradually acquires a larger size, becomes soft, and somewhat prominent in the middle, or towards its most depending part, the inflammation has ended in _suppuration_.

The worst, but happily the least frequent consequence of common inflammation, is the death or mortification of the part affected. The signs of this disastrous event are a change of colour in it, from being of a bright red, to a livid hue; small vessels, filled with a thin fadid serum, arise on its surface, and air is plainly felt to exist in the disordered locality. The pain, indeed, is diminished, but the pulse sinks; while the tumour is gradually metamorphosed into a black fibrous mass.

These are the three most usual terminations of inflammation. By many writers, however, another disorder has been treated of, in which inflammation is apt to end—namely, _scirrhous_. But, although that complaint may, perhaps, in a few instances, follow inflammation, yet it is far from being a common consequence of it. Hence, although inflammatory affection may justly be mentioned as one of the many exciting causes of scirrhous, yet the consideration of this disorder cannot with propriety be introduced into an account of inflammation.

Common inflammation, particularly when it affects glandular parts, is often observed to leave indurations behind it. Such indurations, however, are not at all malignant, and are very different in their nature from what is implied by a real scirrhous.

**TREATMENT OF INFLAMMATION.**

The grand principle to be observed in the treatment of inflammation, is to endeavour to lessen that inmoderate action of the arteries, which is now commonly considered as the proximate cause.

The first circumstance to be attended to, in all cases in which resolution is to be attempted, is the removal of all such exciting causes of the disorder as may happen to present themselves. Foreign substances in wounds, frequently excite inflammation, and ought to be extracted as speedily as possible. A piece of bone, or a nail taken up in the foot, or even a thorn in the leg, often gives rise to the affection, and requires immediate removal. Such things as these may often be detected and removed at once; and this is doing a great deal towards the cure of the inflammation. Many of the exciting causes are only of momentary existence; yet, though they may no longer exist, the process of inflammation continues to follow the violence and irritation which were suddenly produced, and still remain. Hence, when taking away, if possible, the remote cause, it is proper, by other means, to moderate the increased action of the vessels.

If inflammation is consequent on an increased action of the vessels, and if a greater quantity of blood is impelled into, and circulates through the diseased part than is necessary in the natural state, it follows that _bleeding_ must be a principal means of relieving it. The reason of this is, that it lessens the action of the whole arterial system, and, of course, of that part which is affected, and thereby diminishes the quantity of blood transmitted to the
part affected, by reducing the whole mass in the circulation.

Bleeding, however, is often misemployed, especially when regarded as the only remedy for this disease, and other steps are neglected. The obstinacy and vehemence of the process, in weak constitutions, prove that depletion is not invariably proper. When inflammation is combined with an unhealthy state of the alimentary canal, blood should be taken away with great caution. A great deal of induration, with little pain and heat in the inflamed part, the probability of a long and copious suppuration, and the dependence of the inflammation on local weakness, are particular instances in which phlebotomy should be sparingly employed. Bleeding is quite unnecessary when the disease is local, and symptomatic fever low.

On the other hand, bleeding is highly beneficial in all cases in which the disease is simple and uncomplicated, and attended with a high degree of febrile disturbance. Hence, inflammation of the eye, which is a most sensitive part, particularly requires a free evacuation of blood. Inflammation of the lungs, brain, or stomach, which are organs, the sound state of which is highly essential to the regular continuance of all the various operations in the animal machine, particularly demands the employment of the lancet; for, if a successful effort is not promptly made to stop such inflammation, death itself, in all probability, will be the result.

The sooner that bleeding is practised, the greater will be its efficacy, and the more rapidly the blood will be evacuated. Bleeding near the part affected is usually more effectual than when done in a remote situation. These remarks chiefly relate to general bleeding; but in local inflammation, topical bleeding is scarcely ever improper. It is always a point worth considering, whether bleeding in or near the part, will answer better than taking blood from the general habit; for less may be removed in this way, and the constitution not so much affected. Although, in many cases, the general habit may be relieved by bleeding, yet the part specially affected will always require this most. That local bleeding has a very considerable influence on the inflamed part, is proved by the sudden relief obtained from it.

The modes of performing local bleeding are by the lancet; or, if in the feet, by first removing the horn with the drawing-knife, and puncturing the vein with a strong abscess lancet; other parts, such as the thigh-vein, pastern, &c., are also bled with the lancet; the eye, likewise, with the small eye-lancet, the temporal artery, &c. But never bleed in the jugular or the plate-vein with any other instrument than the common phleme and blood-stick; but particularly the jugular, for should a misfortune happen with any other instrument, an action at law might be the consequence.

In continuation of the treatment for inflammation, the bowels must not be forgotten; and in exhibiting medicine in such cases, great care is necessary. The exhibition of small doses of aloe is good, or Glauber's salts, in the shape of draught, will be found very efficacious, and is a principal means of diminishing inflammation.

Direct purging is in nowise to be recommended; as it frequently ends in superpurga-
tion and death. Saline medicines must lessen the quantity of circulating blood, insasmuch as they increase the secretion from the intestinal arteries. Hence they must operate beneficially in the cure of local inflammation, much upon the same principle as bleeding does. A very great authority and writer, was of opinion, that purging lowers action without diminishing strength; by which we are probably to understand, without producing a very lasting or permanent loss of strength. With respect to mild laxatives in inflammation, none are preferable to the above; but, of the two, the saline draught is preferable to the aloetic. We may here remark, that besides the benefit which the local inflammation derives from the judicious administration of purgatives, the costiveness and heat which usually attend the symptomatic fever, are also relieved by the same means.

Nauseating medicines, which have the power of producing sickness, lessen, for a time, the action, and even the general powers of life. This is in consequence of every part of the body sympathising with the stomach, and the effect may be very quickly excited. Sickness lowers the pulse, makes the small vessels contract, and rather disposes the skin to perspiration. But nothing more than nausea should
be caused. Nauseating medicines employed after bleeding once or twice, are often productive of considerable benefit; but there are some affections in which they cannot be used, such as inflammation of the stomach and intestines. In all superficial inflammations, however, they may be safely and advantageously exhibited, as well as in most internal inflammatory affections, especially in the lungs. Indeed, in every instance in which there is an urgent reason for putting a sudden check to the continuance of the affection, they may be used. The employment of nauseating doses of white hellebore or digitalis, to the amount of 1 1/2 to 2 drachms, three or four times a day, is very efficacious.

**Opium** has been frequently recommended by many veterinary surgeons; and we have seen its good effects, especially in inflammation of the bowels. During its employment, the bowels should be kept open by elysers. Care must be taken to give it in sufficient doses; for small quantities not only fail in fulfilling the object, but frequently produce quite an opposite effect. It likewise occasions a moisture on the surface of the body, which experience shows is eminently serviceable in all inflammations. Opium, combined with aloes, is an excellent remedy in cases of inflammation of the feet; no person but such as may have used this drug, would believe the relief given to so painful a disease.

In all cases of inflammation, corn must be prohibited; and even when the inflammation is abated, great care must be taken in administering anything of a highly stimulating nature. Watery, cooling, mucilaginous drinks, taken in a lukewarm state, are the most proper, such as oatmeal gruel, and mashes of bran with chilled water. These take off heat, and tend to soothe the increased action of the whole arterial system. The stable in which the horse is kept, should not be warmer than his comfort requires; for, of all things, heat keeps up any increased action in the body in the most powerful manner. For the same reason, the animal should not be covered with a superfluous quantity of clothes.

The whole body, but more especially the inflamed part, should be preserved as free as possible from every kind of motion. Exercise, and muscular exertion of every kind, accelerate the circulation; and hence their pernicious effect on inflammation, by determining a larger quantity of blood to the part affected.

With the exception of what has been stated concerning topical bleeding, all the foregoing remarks relate to the general treatment of inflammation. We shall next consider its local effects.

It has been already observed, that inflammation is attended with an increase of heat in the part affected; and it is a well-known fact, that the action of the arteries, as well as any other action carried on in the animal economy, is promoted and increased by the influence of heat. For this reason, an obvious mode to be pursued is, to reduce the temperature of the inflamed part by the topical application of cold; and, in particular, by continually abstracting the heat generated in the part, by keeping up a constant evaporation from its surface.

Preparations of lead, and other sedative and astringent substances, are such as are in the greatest repute for bringing about the resolution of inflammation.

We have remarked, that cold applications used in the resolution of inflammation, are commonly such as are of an astringent and sedative quality; but the whole class of medicines which are found to possess these properties, can never be recommended as topical remedies for phlegmonous inflammation. The sulphate of zinc, and sugar of lead, combined with vinegar, are the only medicines of an astringent and sedative class, which seem to have acquired permanent celebrity for their efficacy in resolving inflammation.

Extensive experience, and long-established trials, have now fully confirmed the virtue of all local remedies, in which the sugar of lead is the active ingredient. The preparations of lead certainly merit the appellation of sedatives. An abatement of the different symptoms of pain and tension, and the communication of an agreeable soothing sensation to the part, are almost always the direct palpable effects. Every man of experience and observation will allow, that while there is a chance of accomplishing resolution, no local applications to phlegmonous inflammation are, in general, so proper as cold lotions, containing the acetate of lead.
Many objections have been raised against the lead lotion, from its poisonous quality, but, in inflamed parts, there is an impediment to absorption, and this circumstance may tend to render the employment of lead a matter of safety.

Sugar of lead, with vinegar and water, as follows, is the best method of applying it.

Sugar of Lead . . . . 4 drachms.
Dissolve in Vinegar . . . . 4 oz.
Then add Water . . . . 2 lbs. (1 quart).

When not inclined to employ a solution of lead, try the sulphate of zinc. For this purpose, four drachms of this metallic salt is to be dissolved in a quart of water. Take a piece of linen, well wetted with the lotion, and apply it to the inflamed part.

Many persons ascribe very little real efficacy either to the acetate of lead, or sulphate of zinc, contained in the above applications; and they attribute all the good that is produced, entirely to the evaporation kept up from the surface of the inflamed part, and to the coldness of the fluid in which the metallic salts are dissolved. Those who entertain these sentiments, think the application of cold water alone, quite as efficacious as that of any medicated lotion whatever.

There are particular cases of inflammation in which the extravasation of blood and lymph into the interstices of the inflamed part is exceedingly copious, while the swelling is considerable, and the pain not particularly great. In such instances, it is a grand object to rouse the absorbents, in order to remove the extravasated fluid; and with this view, a more powerful dissecting lotion than the Saturnine one should be employed. Sometimes it is better to use embrocations and liniments, than any sort of lotion; and we have found it to succeed in general the best; and for this purpose recommend

Oil of Turpentine . . . . 3 oz.
Olive Oil . . . . 3 do.
Mix, and apply to the part.

Or, take

Mustard Oil . . . . 4 oz.
Apply this alone, and it will be found very efficacious, especially if the disease is in the joints.

When the part affected is not very tender, or when it lies deep, applications of hot vinegar, or the Saturnine lotion, have been applied, but with little or no good effect. Alcohol and ether have acquired some celebrity as local remedies for inflammation. Perhaps one great reason why they are not more extensively used in this way, is the expense attending such treatment, as these fluids evaporate with great rapidity. Alcohol may possibly prove useful from its astringent qualities; but it seems much more rational to ascribe its virtue, as well as that of ether, to the powerful manner in which the evaporation of such fluids deprives the inflamed part of its heat.

WARM APPLICATIONS, EMOLLIENT POUltICES, AND Fomentations.

The absurdity of attempting to reconcile every useful practice with a philosophical theory, is, in no instance, more strikingly exemplified than in the opposite descriptions of local applications which are deemed of service in inflammation. The generality of cases undoubtedly receive most relief from the use of cold sedative astringent lotions; but there are constitutions and parts which derive most benefit from the local employment of warm emollient remedies.

Inflammations of the foot, broken knee, and strain of the back sinews, may be specified as examples in which, generally speaking, warm emollient applications are better than those which are cold and astringent. In all cases of inflammation, however, which manifestly cannot be cured without suppuration, the emollient plan of treatment ought to be at once adopted, as in either fistulous withers or poll-evil; for the sooner the matter is formed, the sooner the inflammation is stopped. The inflammation attending gun-shot wounds, is of this description; also, injuries received from the goring of cattle in the field, &c.

Warmth and moisture together, or, in other words, fomentations, are commonly had recourse to, in cases of inflammation; but when the warmth is as much as the sensitive principle can bear, it excites action. In many cases warmth does no good, and therefore it might be supposed to increase the action of dilatation, and do harm; but if the pain should arise from the contraction of the inflamed vessels, benefit would be the result, though we must doubt whether this change is produced,
as making the vessels contract would probably give ease.

In addition to what has been already observed, it seems almost impossible to give any useful practical advice, with respect to those cases in which warm emollient applications should be used in preference to cold astringent ones. The veterinary surgeon, however, who consults the feelings and comfort of the animal under his care, will seldom commit any serious error. Hence, in all cases in which the first kind of topical applications seem not to produce the wanted degree of relief, let the second sort be tried. From the opportunity of comparison, a correct judgment may then be easily formed.

Regarding poultices, the linseed meal should take the preference, and it is easily prepared. Put as much hot water into a basin as the size of the poultice requires; previous to which, mix the meal with cold water, so that it does not clot in lumps when brought into contact with the hot water; then gradually mix, till the mass is of a proper consistence. Very frequently, a little sweet oil or hog’s lard is also added, to keep the application soft and moist for a longer time.

Fomentations are excellent; and in most cases of recent inflammation, as strains or bruises, nothing can be better. The benefit we have perceived from the application of warm fomentations, has been surprising.

By pursuing the treatment here recommended, the resolution of the inflammation will, in general, begin to take place, either in the course of three or four days, or in a shorter space of time. At all events, it may usually be known, before the expiration of this period, how the disorder will terminate.

If the heat, pain, and other attendant symptoms abate, and especially if the tumour begins to decrease, it may then be considered almost a certainty, that, by a continuance of the same plan, a total resolution will, in time, be effected.

On the other hand, when all the different symptoms increase, and particularly when the tumour becomes larger and comparatively soft, attended with a more violent throbbing pain, it may then be concluded that the case will proceed to suppuration. Hence, an immediate change of treatment suggests itself; and such applications as were proper while resolution seemed practicable, are to be discontinued, and others substituted. This remark refers to the employment of cold astringent remedies, which, when suppuration is inevitable, only do harm, by retarding what cannot be avoided, and by affording no relief of the pain and other symptoms. If the inflammation, however, should be already treated with emollients, no alteration of the topical applications is requisite, in consequence of the inevitability of the formation of matter. Indeed, emollient poultices and fomentations are the chief local means, both of promoting suppuration, and of diminishing pain, violent throbbing, &c., which always precede this termination of inflammation.

When the system is too much reduced by the injudicious continuance of the vigorous antiphlogistic treatment, the progress of the ensuing suppuration is always retarded in a disadvantageous manner, and the animal becomes too weak to support either a long-continued, or a profuse discharge, which it may not be possible to avoid; but which should be especially noticed.

CHAPTER XXVI.

FEVERS.—FEVER IN GENERAL; INFLAMMATORY FEVER; COMMON FEVER; DISTEMPER, OR INFLUENZA; MALIGNANT FEVER; SYMPTOMATIC FEVER; CATARRH, OR COMMON COLD.

Under the head of Fever in General, we can only class inflammatory fever as belonging to the horse. It is particularly interesting to veterinary surgeons, as being the frequent
THE HORSE, AND

consequence of surgical operations, especially after firing or blistering.

This fever is known and distinguished by several names; some calling it inflammatory, some symptomatic, and others sympathetic. It is sometimes idiopathic; that is to say, it occasionally originates at the same time with the local inflammation, and from the same causes. In other instances—indeed, in all ordinary surgical cases—it is symptomatic, or, in other words, it is produced, not directly by the causes which originally produced the inflammation, but in consequence of the sympathy of the whole constitution from the disturbed state of the part.

The idiopathic inflammatory fever is said to be always preceded by chilliness. The symptomatic, or sympathetic inflammatory fever sometimes takes place so quickly, in consequence of the violence of the existing cause, or of the local inflammation, that no preceding coldness is observable.

If, however, the local inflammation is more slowly induced, and consequently operating more gradually on the system, then the coldness is evidently perceived.

The symptomatic fever induced by wounds or other injuries, is excited more slowly, and its period of formation is longer. This fever is not produced when the inflammation only affects parts in a slight degree, but it constantly makes its appearance if the local inflammation is considerable, or if it affects very sensitive parts.

The degree in which this fever is excited, does not altogether depend on the absolute quantity or violence of the inflammation, but, in a great measure, on the degree of local inflammatory action, compared with the natural power and action of the part affected. Parts, in which the action is naturally slow, are extremely painful when inflamed, and the system sympathises greatly with them. Hence the constitution is very much affected when tendons, bones, or ligaments are the parts inflamed. Severe inflammation of a large joint, every one knows, is apt to excite a most alarming, and even a fatal derangement of the system.

In common parts, as muscle, cellular membrane, skin, &c., the symptoms will be acute, the pulse strong and full, and the more so, if the inflammation be near the heart, but perhaps not so quick as when the part is far from it.

If the inflammation is in tendinous, ligamentous, or bony parts, the symptoms will be less acute. The stomach will sympathise more, the pulse will not be so full, but perhaps quicker; there will be more irritability, and the blood will not be so much pushed into the small vessels; and therefore it will forsake the skin.

It seems to be a material circumstance, that parts near to the heart, always exhibit symptoms more violent, and the constitution is more affected, than when parts are situated further from that source of circulation.

If the heart or lungs are inflamed, either immediately, or affected secondarily by sympathy, the disease produces more violent effects upon the constitution, than the same quantity of inflammation would produce, if the part affected was not a vital one, or one with which the vital parts did not sympathise. If the part is such as the vital ones readily sympathise with, then the sympathetic action of the latter will affect the constitution.

When the inflammation is situated in a part not very essential to life, and causes a general affection of the system, called inflammatory fever, the pulse is fuller and stronger than in general, and the blood is pushed further into the extreme arteries, than when the inflammation is in a vital part. The animal, after showing many occasional symptoms, is at first rather roused. The pulse is as described when the constitution is strong and not irritable; but if this is extremely irritable and weak, as in many animals it is, the pulse may be quick, hard, and small, at the commencement of the inflammation, just as if vital parts were affected. The blood also may be sly, but it will be loose and flat on the surface.

The ordinary symptoms of inflammatory fever, accruing in consequence of local inflammation in common parts, are as follows: the pulse is frequent, full, and strong; all the secretions are diminished; the animal is restless; the perspiration is obstructed; the skin is dry and hot; the hair staring; the urine high-coloured, and made in small quantities; and the mouth hot and dry, attended with great thirst. These are the consequences.
TO RELIEVE INFLAMMATORY FEVER.

As the febrile disturbance of the system is produced, and entirely kept up, in almost every instance, by the local inflammation, it must be evident that the means employed for diminishing the exciting cause, are also the best for abating the constitutional effects. Hence, it very seldom happens that any particular measures are adopted expressly for the fever itself, as this affection is sure to subside in proportion to the local lessening or resolution of the inflammation. But when the febrile disturbance is considerable, and the inflammation itself is also considerable, the agitated state of the system may have, in its turn, a share in keeping up, and even in increasing the local affection, and should be quitted as much as possible. However, in these very instances, we should probably be led to a more rigorous adoption of the antiphlogistic plan of treatment, from an abstract consideration of the state of the local inflammation itself, without any reference to that of the constitution. Indeed, the increased action of the heart and arteries, and the suppression of the secretions, require the employment of antiphlogistic means, with alterative medicine, which will, in all probability, restore the animal in a few days.

But we think it right to repeat, that it is hardly ever necessary to have recourse to such an evacuation as general bleeding, merely on account of the fever, as this is only an effect, which invariably subsides in proportion as the local cause is diminished.

COMMON FEVER.

Common fever is a rare occurrence in the horse; but it is not so much its extreme rarity which renders its existence disputed, as that the constitutional tendencies of the animal are such as seldom allow general fever to prevail in him without a more active and local translation of the inflammation to some vital organ.

We have frequently met with this fever, and are convinced that many inflammations of vital organs begin by an attack not local, and confined to that immediate part, but by one which exists in the first instance, as a general, diffused, inflammatory action of the vascular system at large. Most veterinarians are aware, that it is a common practice, when a horse is observed at the very first approach of illness, to raise him by several means. Among horse-dealers, especially, and other proprietors of horses, when disease occurs in the spring of the year, it is the custom to watch them narrowly, and to put some plan into practice of the above kind, immediately after which they frequently observe no more of the complaint. If, however, the first cold fit is passed over without attention, a hot stage generally succeeds. In due time the horse again shivers, his hair stares, and he becomes subjected to other symptoms of illness, and the disease is then fully formed. The means pursued for this end are various; but they are all such as tend to rouse the flagging powers, during the cold fit, into such a degree of increased action, as considerably to overbalance the augmented vascular action produced by the morbid attack, as shall be greater than the increased action of the complaint. It is upon justly appreciating the two degrees of action, and upon putting the forced one against the diseased one in sufficient strength, that the salutary effort consists. Were such a plan to be put into practice when a topical inflammation of some important and vital organ had actually taken place, it would, most undoubtedly, greatly aggravate it; but as in diffused inflammatory action constituting fever, there is a specific character not wholly dependent on the increase of the vascular power, so the production of an artificial action, greater than the diseased one in the earlier stage, will sometimes overcome the febrile one.

The causes of this fever are a plethoric state of the body in general, full feeding, with but little or no exercise, sudden alteration in diet, excessive fatigue, and great and rapid change in temperature. Long deprivation, likewise, from either food or water, particularly the former, may bring it on; but an alteration of cold to heat is certainly the most common of the existing causes, as well as of most of the inflammatory attacks of the horse. The vessels of the skin seem, in these cases, to be first acted on, and this from a sudden chill, in consequence of coming in contact with a cold atmosphere, producing those symptoms; first, a shivering fit, the skin shaking violently, the hair staring, the legs, ears, and muzzle feeling intensely cold. All these symptoms remain
according to the violence of the attack. The horse's mouth is generally found dry and hot, and he is seen frequently to lick his lips, as if he wished for some moisture. The skin is found alternately hot and cold, with occasional sweatings; the bowels rumble, and are flatulent, and he appears altogether uneasy, and seems more in want of a restorative than anything else, by which means the debility and fever would be carried off.

Such is usually the first stage of fever; but it is very common for it, at this period, to sink its specific character of true fever, into a local attack on some particular organ, as the brain, lungs, bowels, kidneys, and not unfrequently the feet. Under any of these circumstances, the primary character of fever is lost, and the remaining febrile symptoms become secondary and symptomatic.

The preference it may have in these instances for any one organ over another, is not easily accounted for; but it may be connected with local circumstances, particularly with such as have had a tendency to produce an unusual determination of blood to a part. Violent and long-continued exercise will induce a disposition to it in the lungs, from the very great quantity of blood forced through them during exertion. Water, if thrown over a horse when hot, is very apt, by checking perspiration, to bring on a state of the bowels, or of other viscera, predisposing them to inflammation.

A heavy and awkward rider, travelling a great distance, subjects the kidneys to such injury, that they often require but little additional stimulus to assume inflammation. It is equally notorious, that severe riding in the snow, or the custom of washing the feet when a horse is very hot, particularly in frosty weather, will produce, by reaction, a determination of blood to these parts, with a febrile irritation. The consequence of severe and injudicious management, may, by translation, be converted into acute founder, and such appears the origin of many acute founder cases. The disease is then said to have settled in the horse's feet. It remains to be noticed, that independent of these purely local attacks, there is great reason to believe that this fever not unfrequently degenerates into the catarrhal epidemic; for many cases which commence with a simple rigour, are often prevented from proceeding further by overcoming the first attack.

Should none of these attacks occur, however, but, on the contrary, should this fever remain, after the first stage, purely idiopathic (which is very seldom the case), it is invariably the same in any two subjects, although marked by sufficient general characters to describe them. The pulse loses fullness, but is hard, and increased in quickness.

What we have described, may be considered as constituting the principal stage of this fever, to which, under favourable circumstances, there succeeds a softer and less frequent pulse. The countenance looks more lively; and although the muscular weakness rather increases, the irritability lessens, the secretions also return to their natural state, the mouth feels cool and moist, and the heat of the body becomes gradually natural. Slight symptoms of returning appetite also appear, under which circumstances a resolution of the fever is formed.

For the treatment of simple fever, which generally comes on after a journey, the groom should immediately report the same the instant the cold fit or rigour comes on; then procure two or three men to work at the horse with dry straw with all their vigour, whilst he, in the meantime, is preparing the following draught:—

| Good Ale (warmed) | 1 quart |
| Ginger | ½ oz. |
| Anise Seeds | ½ do. |

Give immediately; and after rubbing the animal well, clothe him warm, give him a good bed of clean straw, and bandage his legs up with flannel. Should the reader have one of the cordial balls, recommended in the list of medicines at the end of the first section of this work, take one and break it up, and dissolve it in the warm ale. If warm ale cannot be immediately procured, take half-a-pint of gin, and three half pints of water, to which add either the ginger or the cordial ball. On the morrow give the following alternative:—

| Cape Aloe | 2 drachms |
| Juniper Berries | 1 do. |

Form into a ball with soft soap, and sufficient linseed meal.
After this feed the horse as usual. He will be fit for work in two days' time.

The distemper, or influenza in horses, attacks them at all seasons of the year, and under almost any circumstances; but it is infinitely more prevalent at some times, and under some circumstances, than at others. This is especially the case in the spring, near the sea-coast, and when the wind is blowing off the sea from the south-east. This has been demonstrably proved. No age is exempt from this disease. In large towns, horses are very liable to it, particularly if their heads are fastened in a south-east direction, and the rack at the top left completely open. Occasionally, however, it rages in a truly epidemic form, when the liability to its attack is almost uniform among all varieties, with the exception that, even under this state, young animals, and those newly brought into stable management, are more liable to it than older ones. The spring appears to be the time of year when they are most subject to this disease, the prevalence of which is materially increased by the variable state of the atmosphere, as in great and sudden changes from dry to wet, and from heat to cold, and still more certainly if these are accompanied with an easterly wind. Now and then it is found to occur in wet autumns also. It has been disputed whether it is contagious; but on this point we do not think it difficult to decide, for we have seen a number of horses stabled together, and some of them not the least affected, while others, standing near them, have suffered greatly from an attack. This can only be attributed to the susceptibility of the constitution of some to be affected by the disease more readily than others, though it may appear to exhibit all the characteristics of contagion.

Many foreign writers have fallen into the same error with some of our English veterinarians, and confounded this disease with percocmia, and other diseases of the chest. This mistake is not to be wondered at in practitioners of moderate experience, from the circumstance of these diseases possessing some symptoms in common, and, in fact, from itself frequently terminating in that complaint; but this is to be attributed more to unskilful treatment than to a disposition of the disease, in itself, to such a result; for, in a sea-coast practice, we could count, in one year, three hundred cases in which not a single patient was lost.

The first indication of the disease is a loss of appetite. The horse looks dull and heavy; his legs and ears are cold; his mouth warm and dry; and he frequently attempts to blow his nose, from which comes a purulent discharge, and he breathes rather hard. The parotid glands under his ear, and extending to the angle of the jaw, are much swollen. Sometimes the submaxillary gland, between the jaws, become swollen, but not frequently. His ears continue cold, and he coughs dreadfully; the violence would almost lead to the belief that some important organ would be ruptured. This continues sometimes for three or four minutes, with such distressing violence to the horse, that it pains the observer. Sore throat is always an attendant on inflammation of the tonsils. The animal cannot swallow his drink but with such difficulty as rather to resemble sucking than swallowing; if he is inclined to eat, the hay is quidded, and returned again, from an incapability of passing it over the glottis. Sometimes the inflammation proceeds down the windpipe, and then the cough is extreme. It is also sore to the touch on the outside of the throat. Indeed, in some cases, the horse evinces great restiveness when the hand is laid on his throat, on the enlarged glands, or the windpipe. In some cases the discharge from the nostrils becomes of a mucous character; but this is a favourable omen.

The causes of this disease, as before described, are principally dependent on a variable atmosphere, acting upon a peculiar aptitude in the constitution of the horse to become affected. In some years, this aptitude is more general than in others; and if an unusually variable temperature takes place in the climate, with atmospheric moisture, the disease assumes a more epidemic type.

In treating for it, the animal must never be bled; for, what is this distemper?—nothing more than sore throat, which may extend as before described; but, then, bleeding is bad, because no vital organ is affected. Remove the soreness from the throat, and the animal gets well. The very fact of the horse having a difficulty of swallowing, proves that the distemper extends little or no farther than the rima and epiglottis, the membranes of which
are of such a delicate nature, that certain atmospheric changes will affect them. The means of cure are so exceedingly simple, that it almost doubly strengthens this fact. Use the following receipt, which will seldom, if ever, be found to fail:—

Glauber Salts . . . . . 4 oz.
Linseed Meal . . . . . 2 do.

Let these be well mixed with two quarts of hot water; and when of a proper heat, let them be carefully horned down. Repeat them night and morning.

This draught will lower the inflammatory action that may be going on in the system, and the horse’s mouth will get gradually cool, and everything in the shape of fever leave him.

In such cases of this distemper, the attempt to give a ball cannot be made, for the soreness of the horse’s throat will prevent him from swallowing it. Let warm water, or chilled water, in which a handful of oatmeal has been mixed, be placed in his manger, so that he may indulge in it should he think proper. If his bowels should at all appear costive, back-rake, and give two or three olys, until there are evident signs of a relaxation of the bowels. If the horse should make frequent efforts to blow his nose, without discharging anything, apply a nose-bag made of coarse cloth, with a portion of scalded bran in it to steam his head. This will produce the desired discharge, and you may rest satisfied that he is progressing towards a better state. Bandage his legs, and dress him well; give him good warm bedding, and prevent, as far as possible, all draughts from entering the stable. For food, bran mash will be the best thing, but only in small quantities, and cold, for he will not eat much until the soreness of his throat is removed. If large quantities are given at once, and the discharge from the nose becomes copious, he will refuse his food afterwards. Horses will scarcely touch warm bran mash at any time of the disease. Therefore, if a few vetches or grass can be procured for him, he will be most likely to eat them. To remove the soreness of the throat, make use of counter-irritants; the best of which is composed of the following ingredients:—

Oil of Turpentine . . . . . 3 oz.
Olive Oil . . . . . 3 do.

Mix, and rub this liniment all round the throat, on the swelled glands; and if the disease should have been of some days’ standing, rub on about half-way down the neck, as far as the windpipe can be felt. Should this liniment not be found sufficiently strong, take of

Mild Blistering Liquid . . . . 4 oz.
and apply to the parts, morning and night. (See List of Medicines.)

In consequence of the difficulty of swallowing, and the consequent debility arising from the want of proper nourishment, the horse naturally becomes weak, and requires art to assist nature, after all febrile symptoms are gone, which will easily be ascertained by the recovery of his appetite, the coolness of his mouth, and his spirits being greatly enlivened.

At this time you may venture to give him the following tonic ball:—

Saltpetre of Iron . . . . 12 drachms.
Aloes, Cape . . . . 6 do.
Gentian . . . . . 12 do.
Mix, and form into a mass with honey.
Divide into six balls, and give one every morning.

In proceeding as before described, no fear need be entertained as to success in curing the distemper, no matter in what shape it may have made its appearance.

MALIGNANT FEVER.

Malignant or putrid fever in horses is of rare occurrence; and when it does occur, it is generally a sequel of the distemper just described; principally arising from the debilitated state to which the animal is brought by too much bleeding for that disease. The system is consequently so much lowered from its natural standard, that the disease may take on a putrid or typhus form. When the disease, from improper treatment, is allowed to arrive at this state, it then may, in some measure, be said to become infectious, but not in any other form of the disease.

The malignant epidemic of horses always commences by similar appearances to those which characterise the mild epidemic. In fact, the one is only a heightened degree of the other, pushed into a putrid type; not by the violence of its action, as supposed by some, but by reducing the arterial system below its proper standard. Another proof of this
debility existing in the malignant kind, is seen in the purging which is usually present, and a fetid, stinking discharge from the nose also. The breath is likewise particularly disagreeable, and the pulse quick and small, attended with extreme weakness.

In treating of malignant epidemic, it is hardly necessary to say anything about bleeding, as that may be considered the principal cause of the disease. As soon as any appearances of malignity present themselves, the most active means must be employed to support the strength, raise the action of the system, and destroy the putrid tendency. For the accomplishment of this, take a nose-bag, and fill half-full with bran; then take

Chloride of Lime . . . . 2 oz.
Water (warm) . . . . 1 gallon.

Moisten the bran with this liquid, and put the bag on the horse’s head, that he may inhale the chloride, which will remove the putrid tendency. Care must be taken not to have the water too hot. Repeat three or four times a day, for about half-an-hour each time. Give malt mashes, and nutritious glysters, either of rice-water or starch, and administer the following ball:

Cantharides . . . . 5 grains.
Arsenic . . . . 5 do.
Sulphate of Iron . . . . 2 drachms.
Aloes, Cape . . . . 1 do.
Juniper Berries . . . . 1 do.

Let these be well incorporated with honey, and given every morning, or every second morning. By this method of treatment a successful termination of the disease may be anticipated.

SYMPTOMATIC FEVER.

A symptomatic fever is a degree of inflammation and increased circulation, occasioned by some distinct or local pain, and is not a disorder within itself; but probably the effect of, and dependent on, some other disease for its being produced. This fever is so influenced by the cause, and so entirely regulated by its changes, either for better or worse, as to be constantly reduced to an alleviation of the original complaint, and totally dispelled by a removal of the disease to which it is a concomitant. The fever being only a symptom of some other, the mere effect of preternatural heat excited by extreme pain, and not a distinct disease, let the original cause be removed, and, as a matter of course, the effect will cease.

It has been repeatedly urged by authors of great repute, that every fever is one and the same disorder, only appearing differently, according to the various circumstances it meets with in different constitutions; and much might be advanced in favour of this assertion. For want of due attention to the difference of stages, many fine horses have been hastily condemned. Persons should not only be accurately nice in the discrimination of disease, but, by attending minutely to circumstances, endeavour to develop the indications of nature, and strengthen all her efforts. In such cases, no person can be too well acquainted with the qualities of medicines, or with what is to be expected from their effects; and should have in view, on every emergency, their operations, whether certain or probable relief is to be obtained. These ends should be promoted by every fair and gentle means which circumstances may justify, or discretion dictate.

Symptomatic fever is most frequently brought on by a general cutaneous obstruction, or sudden constriction of the pores of the skin, which will constitute the foundation of every fever to which the animal can possibly be subject. Inflamed feet will produce it; tumours of almost all descriptions; even nailing a shoe on too tight will produce symptomatic fever; besides wounds, and almost all operations that are attended with severity, blisters, &c.

With respect to symptoms, the most certain of these are, a universal heat, and disordered pulse; a palpable disquietude and uneasiness, shifting from place to place. The horse labours under difficult respiration; his mouth is very dry, his tongue parched and hot; he declines his food, but will drink water; and sometimes seizes his provender with seeming eagerness, then drops it in disappointment. The body is generally costive; and in the early stage of disease, there is a slight proportion of obstruction of urine.

Let a fever proceed from whatever cause, the modes of cure are still the same; such as diminishing the preternatural heat to that degree which constitutes its healthy state. 267.
Remove all internal obstructions; and by a proper and judicious administration of medicines, calculated to subdue the original cause, all dependent symptoms will certainly subside. For this purpose administer emollient clysters, after having back-raked the horse, so that easy evacuations may be promoted, and give

\[
\text{Digitalis} \quad \text{from 1\frac{1}{2} to 2 drachms} \\
\text{Aloe, Cape} \quad \text{1 do.}
\]

Make into a ball, with soft soap.

Administer one every morning, which will lower the action of the heart and arteries, and entirely remove their inflammatory action: or give the saline draught, as prescribed. (See List of Medicines). Give nitre, about an ounce in the horse’s water every night; feed with bran mashes, or green food, if it can be provided fresh; if not, a few sliced carrots mixed with his mash, and a handful of oats, will entice him to eat, and prevent that considerable debility which frequently arises from symptomatic fever. Have his legs well rubbed, and moderately clothed, and let him be well littered down with clean dry straw.

**CATARRH, OR COMMON COLD.**

_Catarrh, or common cold_, is one of the most frequent attacks of fever to which the horse is subject. Cold, indeed, is an indefinite name for catarrh, which consists in an inflammation of the _viva glottis_, or top of the windpipe, which is covered with a highly sensitive membrane, even more sensitive than the nerve itself.

This is the seat of catarrh and cough; and when it is affected, the horse is said to have caught cold. This expression, however, is apt to mislead from the true nature of the real cause; for this cold defines no particular degree in which it has been caught. The truth is, it is the change from one degree of temperature to another, the warm air acting as a stimulus, and the cold as a sedative; and thus people, without reflection, attribute the attack to catching cold. Horses are necessarily exposed to these variations of temperature many times a day; and this is demonstrated particularly in man, without going to individual cases, but to numbers; for, in removing a whole regiment from comfortable barracks to open camp, cold operates, but no catarrh; but on again returning to barracks, which produces the effect of high temperature, catarrh becomes common; and it is a known fact, that deaths are never so few as in the open field.

Horses that are kept in the open field in winter, are not attacked with catarrh, inflamed lungs, grease, &c.; but when brought into the stable, catarrh immediately makes its appearance. This sudden change cannot be referred to simple heat, but to a poisoned atmosphere, which is generated in stables, breathed many times over; nature not having intended animals to breathe the same air a second time. The closer we adhere to her laws, the less probability is there of disease.

Horses will certainly lose flesh by being kept in cold fields; for animal oil wants a certain temperature for its increase. Horse-dealers are well aware of this in preparing their animals for sale. By these facts, different changes are proved; hence badly-constructed stables, and contaminated air, are the veterinary surgeon’s best friends.

Thus, then, taking cold is, properly speaking, taking heat, the disease being of an inflammatory nature.

Catarrh being proved to be an inflammation, originating in congestion, cold cannot possibly produce this, but the direct contrary. This may be proved by bringing a frozen animal to the fire, by which means you excite inflammation, and destroy him; but if you rub him with snow, he revives, because the snow, with friction, is warmer than the body, and becomes of a sufficient degree of heat. But the idea that cold produces catarrh, arises from its existing mostly in cold weather; but what the cold docs is this—it renders the parts more susceptible of heat. Persons may ask, why are the cartilages of the windpipe more particularly affected? The answer is, that they have been made thus sensitive as a kind of safeguard to the lungs; and when we consider that, in bringing horses into stables, it is from cold to heat, and from a pure to an impure atmosphere—this being more than a simple change—the question then arises, how are we to prevent it? We must acknowledge that all animals fatten sooner in a warm temperature than in one of the reverse; but then the change must be gradual, being mindful that the air all this time should be pure; for the
diseases of horses may almost all be referred to ignorance and neglect; and, in the same manner, this will, to a very large extent, apply to all animal creation.

As it is necessary to have horses stabled, for our many frequent uses, pure air has as much to do with the prevention of catarrh, as anything else; for a poisoned atmosphere produces more or less effect upon all animals, in accordance with their habits. We, ourselves, are born in a comparatively impure atmosphere, and brought up in it; but use with us is second nature. A horse, on the contrary, comes into the world in a pure atmosphere, never breathing the same air twice. Therefore the opposite must take greater effect on horses than on us; and hence we seldom see them ill until they are brought into stables. Then the horse becomes sick, and the owner is surprised; but it ought to be a greater surprise that the animal should live at all. Although no advocate for cold stables, yet we are no friend to such as are heated by dung and urine.

Horses generally become diseased during the night, the impure air then collecting; for during the day there is a partial ventilation. Most persons on visiting a stable the first thing in the morning, are well aware of the effect of the air on their eyes.

Common catarrh often takes a great hold of the constitution; the irritation causing cough, and not unfrequently ending in chronic cough, from the irritability of the nerves, occasioned by the previous attack. If the inflammation attacks the membrane which lines the nose, a discharge will be the consequence, sometimes from one or both nostrils; nature endeavouring, by this means, to relieve herself. This inflammation frequently, or almost always, affects horses coming into large towns. Horse-dealers are well aware of this, and often try to prevent it, by turning them into a loose place, for the attack seldom or ever comes on whilst they are on the road in exercise, and breathing pure air. Mistaken kindness will often permit them to rest when the journey is over; but, however much the horse may have travelled, he should have walking exercise the next day. The first few days are of the greatest consequence.

The cause of catarrh, according to the doctrine laid down at the Royal Veterinary College, is common cold; but other causes will produce the same effects, and deserve great attention from every possessor of horses.

What is called cold, may arise not only from breathing impure air in stables, but from the real *application of cold*, when the animal is in an excited state, or in a state of perspiration, and allowed to stand in a draught of air.

In this, as in many other diseases to which the horse is subject, cold acts differently upon different constitutions; the injury sustained being in some respects regulated by the degree of heat, or perspiration, in which the animal was at the time of his being exposed to the original cause, from which some idea may be formed of its probable duration and severity. The effects of cold are not only soon discovered where there is constant attention and care, but an observation may be very early made on what part it more immediately directs its attack. In all cases, either of the eyes, throat, or the head, it will discover itself, more or less, in a cough, or in an obstruction in breathing, according to the severity of the attack. So soon as a horse is in this state, a symptomatic fever attends, which is to be understood as a degree of febrile heat, or irritability, dependent on the original cause, and which gradually ceases as the primary disease is found to decline.

In treating for this, bleed moderately, say two or three quarts—not enough to debilitate the animal; that is, according to his size, state, and condition. In about three hours give him a bran mash, having first removed all his hay out of the rack. Mix an ounce of nitre with his water morning and night. Continue this treatment for two or three days, giving occasionally a handful of sweet hay, *wetted*. This, in many cases, when taken in the early stage, will prove successful. Should this treatment not produce the desired effect in the early stages, and should the attack have been neglected, and the disorder have made rapid progress; should the cough be violent and constant, the horse very dull and heavy, declining all kind of food, and the symptomatic fever running high; perhaps the disease will not immediately submit to the above treatment so soon as may be wished or expected; therefore repeat the bleeding in two or three days at farthest, according to the state and necessity, altering
the mashes to equal parts of malt and bran, scalded with boiling water. When nearly cool enough for the manger, stir in it—

Glauber Salts . . . . 2 oz.
Liquorice, powdered . . . . 1 do.

Let this be repeated every night and morning, continuing the noonday feed dry, and the nitre as before. Good grooming and gentle exercise must not be neglected.

It should be remembered, that cough, or colds, thus treated, before they have been suffered by neglect or penury to become obdurate by long standing, generally submit to a very small degree of trouble or expense; whilst tardiness in procuring expeditious relief, is often productive of evils that no future assiduity can relieve. A critical discharge at the nostrils may come on, which may terminate either in chronic cough, broken wind, inflamed lungs, or even in glanders. To obviate these misfortunes, if they do occur, give a dozen of the following balls, not neglecting the nitre in the water:

- Turkey Figs . . . . 4 oz.
- Liquorice, powdered . . . . 4 do.
- Aniseed . . . . 4 do.
- Ginger . . . . 1 do.
- Caraway Seed, powdered . . 1 do.
- Honey sufficient to form into a mass.

Divide into eighteen balls, and give one every morning.

To say precisely in what time the cure will be completed, is impossible; but this method of treatment is strongly recommended.

The treatment for cough, at the Royal Veterinary College, is—

- Cape Aloes . . . . 1 drachm.
- Linseed Meal, about . . . . 2 do.
- Soft soap to form the ball.

Give one every morning. Sometimes a dram of digitalis is combined with the above.

CHAPTER XXVII.

COUGHS; ROARING; CHRONIC COUGH; THICK WIND; BROKEN WIND.

ROARING.

The horse is very subject to this disease, especially carriage-horses, and particularly those of the Yorkshire breed, whose fine upstanding height, of from sixteen to eighteen hands, and their long necks, cause them to be sought after in London for the carriage. In driving them, the coachman is enabled to shorten his bearing-rein to any length he thinks proper, and thereby bring his horses’ necks into a beautiful curve. This is done to exhibit them in style, or what these knights of the whip call, bringing them out in form, though, by such means, the disease called roaring is produced. In many cases where this disease exists, it is exceedingly unpleasant to hear the noise the horse makes every time he breathes; indeed, in some cases, it is so distressing, that from exertion the animal will fall; yet, this tight bearing-rein must be used.

Let us here, however, explain what it is that principally is the cause of this complaint.

Roaring is occasioned by anything that obstructs the air-passages, or, in other words, anything that impedes the air from passing up and down from and to the lungs. Inflammation of the fine secreting membrane which lines the windpipe, will frequently produce it, from an alteration of the arterial action, by which an effusion of coagulable matter may be thrown out, and become organised, and, in consequence, remain as a permanent obstruction to the passage. Inflammation of the lungs will also sometimes occasion it; strangles also will, by producing general inflammation round the throat, frequently cause it. But the most painful cause of roaring is, the tight reining-in of carriage-horses, by which the windpipe becomes distorted, or, in other words, contracted and diseased. The horse, in his natural state,
MODERN VETERINARY PRACTICE. [CHRONIC COUGH.

feeds off the ground; consequently, his neck is at full stretch; but when he becomes domesticated, this natural stretch of it is removed from him, for he has his rack level with his head, and the manger but little lower, so that those muscles of the throat, connecting the wind-pipe with the spur-bone, as it is sometimes called, and the inner sides of the posterior part of the jaw, become, in a manner, useless; consequently, contraction takes place; and as nature finds but little or no use for them in such a case, so absorption takes place, and they become shortened. It is from this cause that we frequently see cart-horses, when turned out to grass for a few hours, spread their fore legs so extraordinarily wide. This is the natural consequence of their not being able to reach the ground from the contraction and absorption of a portion of these muscles.

Another cause, and, perhaps, the principal cause of roaring, is the partial absorption, or lapping over of the ligamentous cartilage union existing between each ring of the windpipe, from the horse's head being so briddled in by the bearing rein. (See Plate.) It has been remarked by a very eminent practitioner, and one particularly so at the Royal Veterinary College, that the throat-strap being buckled too tight may be the cause; but, if this were the case, not one out of every cart or waggon horse would escape, especially when we take into consideration the heavy harness with which they are appointed; but this is not the case with carriage or saddle horses, the harness of which is of the lightest description, and especially at the present day.

In treating for roaring, we must premise that its cure is very difficult, indeed not practicable. It may, however, be prevented; and, as "a preventive is better than a cure," we will endeavour to describe how this is to be accomplished. In the first place, the rack out of which the horse eats his hay should be altered. It should be on the ground, so that the horse's neck shall be on the full stretch; or as it is in a state of nature when in the act of cropping his food. By this means, those ligamentous attachments of the rings of the windpipe would become elongated, or be kept in their natural situation. That corrugation of the membrane, which might, under other circumstances, become thickened, would be removed, and so prevent a contraction or reduction of the compass of the air-passage, by which the unpleasant noise of roaring is produced. Nature never intended a horse to have his hay just opposite his nose. All horses in India feed off the ground, and it is a rare thing to meet with a raorer there.

CHRONIC COUGH.

Chronic cough consists in a violent action of the diaphragm, and the abdominal muscles producing a forcible expiration of the air from the chest, ejected with much violence, with the intent of removing any extraneous body that may intercept the passage of the air. Whenever it accompanies a general affection of the constitution, it most frequently assumes the chronic form. Catarh, and inflammation of the lungs, are usually attended with cough; and even if those diseases are removed, chronic cough supervenes. It is, also, a very common attendant of thick wind, broken wind, glands, and pulmonary consumption. Worms also will produce coughs. It also exists, at times, without any attendant difficulty of breathing, the horse eating well, and appearing in good condition. Sometimes a chronic or permanent cough appears to affect the animal when going to stable in the morning, or at the different feeding times. This is in consequence of admitting the cold air into the stable, which becomes a source of irritation to the air-passages. It is no uncommon thing for horses, on first goin'; out to exercise, to cough; but this is in consequence of coming in contact with cold air. A cough of this description is very common, and will sometimes affect the horse for years, yea, even his whole life. In other instances it does not end in so harmless a manner; but, upon any occasional cold taken, becomes aggravated; and when this repeatedly occurs, the bronchies become so permanently affected, that chronic cough is established.

The effects and termination of chronic cough are dependent in a considerable degree upon the causes producing it. From what we have observed of the termination of inflammation of the lungs, it will be easily seen that an irritation often remains in the air-passages after that disease, as well as in some cases of catarrhal affections. In either of these cases,
any change of atmosphere excites these excessively irritable parts into action; making the horse cough whenever he is moved in or out of the stable; for the air being either hotter or colder than what was before breathed in the regular way, becomes a source of irritation. Drinking cold water will, from the same reason, produce the same effect for a time, if given in the stable; but if a horse is allowed to drink at a pond, where the water is of the same temperature as the atmosphere, no ill effects will result. Any irregularity of motion or hurry in the pace of the animal will produce this cough; and in some cases, it is continued to such a length of time, as to be truly distressing. There are instances in which the irritability of the bronchial membrane itself, does not seem so much increased as to alter either the quantity or quality of the mucus secreted. It may become inordinate in quantity, where horses, when they cough, discharge it at the nose, or it may be more acrid in quality; but, in either case, it proves a source of continual irritation. In some cases, the deposit of adhesive matter in the air-passages, arising from catarrhal inflammation or inflamed lungs, will produce chronic cough, and the deposit will then cause irritation. This deposit of lymph-like matter is sometimes removed by the violence of the cough; and by administering expectorants, a separation is frequently obtained, when great quantities of this obstructive matter is brought up. In some constitutions, a large portion of it becomes absorbed, and this may be assisted to a great extent by administering proper medicines.

The remedies for chronic cough are applied in accordance with the symptoms it exhibits; and when it appears from a want of mucous secretion, we know of no medicine so effective as the ball prescribed in catarrh. On the other hand, if the mucous secretion should flow in such quantities as to cause the horse to be weakened by it, then it will be proper to administer the following:—

<table>
<thead>
<tr>
<th>Substance</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sulphate of Iron</td>
<td>2 drachms</td>
</tr>
<tr>
<td>Gentian</td>
<td>2 do.</td>
</tr>
<tr>
<td>Aloe</td>
<td>1 do.</td>
</tr>
<tr>
<td>Honey to form the ball</td>
<td></td>
</tr>
</tbody>
</table>

One of these balls to be given daily.

If the secretion should be of an acrid, watery description, a course of mercurial medicine should be tried, being careful, at the same time, that the animal does not get a chill during the time this medicine is being given him. The following is recommended as good:—

- **Blue Pill**: 2 drachms.
- **Ginger**: 1 do.

Form into a ball, with soft soap.

Give one of these balls every second day for a fortnight. If the horse should reject his food in the course of the exhibition of the medicine, desist from giving it for a few days, and commence again. This we have known to remove very severe attacks of chronic cough, and frequently, when attended with worms, when the coat was staring and dry, and the stools fetid and slimy.

In chronic cough, great attention should be paid to the food of the animal—never to give clover. It is heating, and altogether unfit for horses so affected. Chaff, also, is not to be recommended in this disease. Good sweet oats and hay, both made a little damp, will be found the best. Carrots, occasionally, are excellent; so also are a few Swede turnips; or even a few potatoes cut up will afford great relief. Occasionally, bran mashes, with a little scalded linseed, will also prove useful.

In cases of chronic cough, where it appears of an aggravated nature, insert a rowel in the chest, and dress with the digestive ointment. (See Ointments, in the medicinal part of this section). Keep the rowel in for at least a fortnight. Should the cough be very severe, apply the following limiment to the whole length of the horse’s windpipe night and morning.

### No. 1

- **Oil of Turpentine**: 3 oz.  
- **Olive Oil**: 3 oz.

Apply as above directed.

### Or, No. 2

- **Cantharides**: 1 oz.  
- **Olive Oil**: 5 do.

Let these remain in a bottle for about six days, occasionally shaking it, and then apply as above directed. In cases of coagulable lymph being deposited in the windpipe, these limiments will greatly tend to remove it.

### THICK WIND

This disease is generally the sequel to inflamed lungs, which has thickened the air-
passages, and consequently prevented a free and unimpeded respiration. It is a disease rarely occurring of itself, but supervening after some other inflammatory attack to which the air-passages may have been subject, such as catarrh, &c. Long-continued exercise, quickened beyond the capacity of the lungs to bear, is frequently a cause; and such is particularly the case when horses are driven or ridden hard with full stomachs. It is also not unfrequently produced when horses are too fat, or, in other words, out of condition, when inflammation is superinduced in the air-passages. Confinement will frequently produce it, by exciting an inflammatory diathesis, especially if over-feeding, with a want of exercise, be added to it.

The remote causes of thick wind are to be found in morbid vascular action. The proximate causes are more obscure; but the examination of morbid subjects, in most instances, shows some disorganisation in the structure of the lungs. A deranged state of the lungs, and especially if the atmosphere is at all thick and heavy, will give rise to it. The most usual appearance it presents, is a morbid alteration in the minute bronchial ramifications of the blood-vessels, occasioned either by a thickening of their own membranous structure, or by a deposit within them of coagulable lymph, which, necessarily, contracts or lessens their functional capacity, rendering air-passages much smaller than they are in a natural state, when difficulty of respiration is produced, and the animal is called foggy, or thick-winded.

Thick wind is easily discovered by any person at all acquainted with horses. A sense of fulness in the right side of the heart induces the animal to respire hastily. The force with which this is done occasions the sound so well known as the distinguishing mark of thick wind, which often degenerates into, what is called, broken wind.

For the treatment of thick wind, there is no better remedy than the cordial pectoral ball, given in the list of medicines at the end of this section, administered occasionally in the morning, when the affection appears, more than usual, to distress the animal, and rendering him apparently less capable for the performance of his duties.

broken wind.

This affection of the lungs and air-passages has a long time puzzled both English as well as French writers on veterinary subjects, but without either being satisfied, until the all-penetrating genius of Professor Coleman, of the Royal Veterinary College, threw a light on the subject before unknown. The theory of that gentleman is a correct one. He discovered it to be a rupture of the air-cells of the lungs, so that the thin membrane covering these, becomes raised up in small bladders, wherever the rupture takes place. This opinion has been thoroughly proved, on examination after death, in such subjects as had been affected with the complaint when living. The alteration in the structure of the broken-winded lung is in general very considerable. It has been asserted that, in very few instances, no change whatever has been detected, and the lungs have presented little or no morbid appearance; but this we should very much doubt, having dissected several horses affected with broken wind, and having examined their lungs minutely, and always found great derangement in them. The alteration consists principally in an emphysematous state, dependent on the air, as above stated, being extravasated not only throughout the parenchyma in minute air-bubbles, but also extended over the thin membranous covering. This extravasation, in most cases, so complete, as to render the lungs specifically lighter than ordinary, and to make them crepitate and crackle under the hand. They are also, in every instance, of a paler colour.

The invariable presence of emphysema in such cases being fully established, it is not to be wondered at that a cure has never been established for broken wind. Some writers have said that there may be a possibility of cure, but without making mention of the curative means. We shall, therefore, offer our opinion as to the best means of relieving the disease, without making any pretensions to the discovery of a perfect remedy.

Where broken wind exists, it is easily known by the peculiar action occasioned by the respiration of the horse. The cough, also, which accompanies it is of a peculiar kind, and seems to be forced out with a sort of
grunting noise. The difference between the inspirations and the expirations—the breathing-in, and the breathing-out—is also most remarkable, but easily accounted for. Inspiration, or the act of drawing in the breath, is effected with the ordinary ease; but the extravasated air already diffused through the cellular tissue, is still the real cause of this difficulty, by offering a resistance to the complete ejection of the atmospheric air contained in the bronchial cells. Consequently, the broken-winded horse inspires with ease, but respires with a protracted and great effort, by means of very forcible contractions of his abdominal muscles. The respiration is performed by two apparent efforts, in one of which the usual muscles operate, and in the other the auxiliary muscles, particularly the abdominal ones, are put on the stretch to complete the expulsion more perfectly. When this has been done, the flank falls with peculiar force, and these muscles resume their relaxations.

Horses affected, may receive a palliative to the distress under which they frequently labour; but a perfect cure is impossible. The best remedy we have been able to discover to relieve broken wind is the following, and ought always to be kept in the stable, especially if the horse is required to do some extra work:—

For Broken Wind.

Gum Galbanium . . . . . . 2 oz.
Ammoniacum . . . . . . 2 do.
Assaefetida . . . . . . 2 do.
Antimony . . . . . . 4 do.

Form into a mass with honey.

Divide into twelve balls, and give one occasionally.

Horses, from their prone position, are liable to pursiveness and broken wind; for in them the intestines press much against the diaphragm, or midriff, and, in consequence, on the lungs, and thereby cause the oppression of breathing. One remedy is, having particular care to their exercise and feed. The exercise should be gentle, and moderate as to its continuance. The food should always be the best of the respective sorts, and frequently given in small quantities, that the stomach may never be too full. All dry food, such as corn, hay, bran, &c., should always be moistened with water to prevent thirst, which generally attends this affection; particularly the hay, the flavour of which is much improved by damping, or sprinkling it with water. The corn should be increased in quantity, and less hay given; and what is given should be of the best description, sweet, clean, and well shaken, to divest it of all dirt and dust. Care should be taken not to make the hay too wet; for, if so, the horse will not eat it.

When there is convenience, broken-winded horses are best when kept out at grass at all times, their corn being continued as when they stood at hay; but when kept at grass for the purpose of relieving their wind, they should not be taken up to stable, except for immediate use; for, if taken from grass to dry meat, they become more oppressed in their breathing, from the difference of the change of food. If convenience cannot be had for constant running in the field, they may be soiled in a loose box in the stable, with any green food that may be in season at the time.

By care, in this method, numbers of horses have been much relieved, and made useful for many years.

There is also a small degree of broken wind, which, by dealers, is called pursiveness. Many pursive horses evince several signs of broken-windedness, yet never become thoroughly broken-winded, if not ill-used, or neglected. Great and foul feeders are always more or less thick-winded; and, except their diet and exercise are carefully managed, they will readily become so.

Due attention being paid to the diet and exercise of pursive horses, according to the directions already given for the broken-winded, tar-water, to the quantity of one or two pints each, may be administered the morning they are going to work. If to this be added a pint of warm ale, it will be found of great benefit in relieving the wind. Another excellent remedy for pursive horses is the cordial pectoral ball. The stable where horses are at all affected in the wind, however slightly, ought never to be without a good supply of this invaluable medicine.
CHAPTER XXVIII.

GLANDERS.

Glanders is a disease, the treatment of which has proved a perfect puzzle to the most scientific veterinarians.

There is no doubt that it is contagious, and it is generally thought incurable. The vast number of horses which have fallen victims to glanders, especially in the army, and in establishments where large numbers are kept, has attracted particular attention to the subject, especially in France and Italy; where, so early as about the beginning of the last century, many attempts were made to discover a remedy for it.

Lafosse, an eminent French veterinarian, considered it a local disease, and thought he had found a successful mode of treating it, in perforating the bones which cover the frontal sinuses, and injecting, through the opening, astringent and other liquids.

After this opinion had been published, some English farriers made a trial of it; and others poured detergent lotions into the nostrils, the nose being drawn up for the purpose, by means of a pulley. Attempts were also made to cure it by arsenical fumigations; and some went so far as to burn out the submaxillary glands between the jaws, or to slough them out by caustics. The various preparations of mercury, copper, iron, and arsenic, have likewise been used. At the Royal Veterinary College, a solution of from two to five draughts of the sulphate of copper, combined with a little linseed meal, is the remedy made use of.

From the circumstance of horses having sometimes escaped the disorder, though they have been standing in the same stall or stable, or drinking out of the same bucket or trough with a glandered animal, many have been led to doubt its being contagious; and the little care that some large proprietors have taken to prevent the spreading of the disorder, in consequence of such an opinion, has been the cause of very numerous and serious losses. That the glanders is contagious, has been clearly and indisputably proved by numerous experiments, and the manner in which it is propagated has likewise been satisfactorily demonstrated. At the same time, it must be admitted, glanders will arise from inoculation; and this not by wilful intention, but from accident; for, suppose a glandered horse to have stood in a stall, and some of the matter from his nostrils to have hung about the manger—a fresh horse coming into that stall, may, from its strangeness, smell about, when any rough substance that he may come in contact with, may occasion an abrasion of the skin. Should this abrasion touch the poisoned matter of glanders, the horse will decidedly become affected.

In a general way, however, close unwholesome stables, hard work, and bad provender, sudden changes from cold and wet weather to hot stables—in short, anything that will weaken the animal considerably, is likely to produce glanders and fary. There will be no longer any danger in admitting this opinion, if, at the same time, we keep in view the contagious nature of the disorder, in whatever manner it may be produced. For, if such cruel and foolish treatment of horses does not produce glanders and fary, it may produce other disorders, which are often more speedily fatal; and if it does not actually produce a disorder, it weakens the constitution to such a degree, that the animal is rendered more susceptible of the contagion of glanders, as well as of other diseases. It is from this cause that glanders spreads so rapidly among post and coach-horses; while, among horses of a different description, its progress is generally slow.

Some writers have said that glanders has often been generated in the cavalry, by putting the horses, immediately after coming from camp, where they are constantly exposed to the weather, into warm stables, and giving them a full allowance of oats. This, it is true, has often brought on inflammation, and inflammatory disorders of several descriptions,
which have proved very destructive, especially the catarrhal kind; in which cases they are accompanied with a discharge from the nostrils. The acrimony of this discharge will sometimes even ulcerate the nostrils, and the disease would then be considered as a decided case of glanders. Frequently we have known the distemper, or epidemic catarrh, produce this effect.

The first symptom of this disease is generally seen in a discharge of glairy matter from one or both nostrils; principally, or usually from one only, and more frequently from the left than from the right nostril; a swelling of the submaxillary glands, or kernels between the jaws, and generally on the side of the jaw corresponding to the affected nostril, and frequently attended with cough; the membrane of the nose, especially that which covers the cartilaginous part, or septum, becomes, from the fineness of its texture, ulcerated; as do the many small blood-vessels distributed thereon. In consequence of this, it becomes more susceptible of the disease, especially in its acute form.

Sometimes, however, glanders is accompanied by a disorder of the superficial absorbents of the skin, named farcy, which has been considered by many authors as a distinct disorder; but we think that it is always a symptom of glanders, whether it appear in a local or constitutional form.

Glanders is divided into two stages—the acute and the chronic; or the first and the second stages. Acute glanders is generally attended with acute farcy, such as chancrous ulceration about the lips, face, or neck, with considerable or painful swellings on different parts; some of these swellings appearing in, what the old farriers called, a corded, or knotted vein. Ulceration and swelling of the hind leg, or sheath, and sometimes of the fore leg, with corded veins, and what is termed farcy-buds on the inside of the limbs, also accompany glanders. Acute glanders often spreads rapidly, and either destroys the animal, or renders him such a pitiable and hopeless object, that the proprietor is usually induced to have him destroyed.

Chronic glanders is generally very mild in the first stage, and does not affect the appetite, or the general health and appearance of the animal. Horses affected no further with it, when properly fed and taken care of, and worked with moderation, will often continue in regular work for several years. Many glandered animals have been known to get rid of the disorder while working; and, on several occasions, fresh-purchased horses, and particularly if old ones, have escaped the disorder. Hence it is that many have been led to believe that the glanders is not contagious.

The second stage of glanders is marked by ulceration within the nostrils, or an appearance in the matter which indicates ulceration, though it is sometimes too high up to be seen. The matter is in larger quantity, more glutinous, sticking about the margin of the nostril and upper lips, and occasionally obstructing the passage of air, so that a sort of snuffling noise is made in breathing.

The matter is frequently streaked with blood, and the horse sometimes bleeds from the nostrils in working. When this happens in the first stage of the disorder, however early it may be, it indicates the approach of the second stage. The matter begins to have an offensive smell, which it scarcely ever has in the first stage. In the second stage, the matter is generally discharged from both nostrils; whilst the glands under the jaw become larger, harder, and fixed more closely to the jaw-bone. They are also generally more tender to the touch than in the first stage. The inner corners of the eye are also matter. The animal loses flesh and strength, and is apt to stale more than usual. He coughs heavily and hard, and at length dies in a miserable condition, generally farced as well as glandered. It is with this disease as it formerly was with small-pox inoculation, and is now with vaccination. If a person happens to meet with one or two cases, or even half-a-dozen, of horses escaping the glanders, after standing in a stable with one that is glandered, he thinks himself fully warranted in concluding that the disease is not contagious. Satisfied with this decision, he gives himself no further trouble about it, and pays no attention to anything that may be said or written in opposition to his own opinion.

It is a remarkable circumstance, that glanders cannot be communicated by applying the matter which is discharged from the nose of a
glandered horse, to the nostrils of a sound one, even though a piece of lint soaked in the matter is put up the nostrils, and kept in contact with the pituitary membrane for a short time, or even if the matter is thrown up the nostrils by a syringe. But if the smallest quantity is applied in the way of inoculation, either to the membrane of the nostrils, or to any part of the body, there will be produced a glanderous ulcer, from which farcy-buds and corded lymphatics will proceed. After a short time the poison will get into the circulation, and the horse will be completely glandered.

The circumstance of glanders not being communicated by applying matter to the nostrils, enables us to account for a horse escaping the disorder, as he sometimes does, after being put into a glandered stable, or standing by the side of a diseased animal. We have great reason to believe that glanders is frequently communicated by accidental inoculation. Glanders can also be communicated by the air, by the effluvium which issues from the glandered horse, in the same way that putrid fever is communicated; yet we knew a traveller who used to journey from Deptford to London daily, and who kept two horses in the same stable, one of which was highly glandered, and remained so for three years; but the other horse never caught the infection, which would lead to the supposition that there must be, in some instances, a predisposition to the disease before it can be caught. Glanders, it has been said, cannot be produced by the matter applied to an old wound or ulcer; but of this we have great doubts. A sound horse has been inoculated with glanderous matter which had been mixed with ten times its weight of water. This produced some degree of inflammation, and a small ulcer of a suspicious nature; but after two or three days the ulcer got quite well. This shows that glanderous matter may be so far weakened by dilution with water, saliva, or the watery secretion from the lower part of a glandered horse's nostrils, when he has the affection in a very slight degree only, as to render its being incapable of communication to others. On the other hand, when a large opening is made in the skin of a sound horse, and a piece of tow or lint, soaked in the glanderous matter, is put into it, in the manner that rows are inserted, the disorder is communicated in so violent a degree, that the animal is destroyed by it, generally in a few days. The same effect may be produced if glanderous matter is mixed with a little warm water, and injected into the jugular vein of a sound horse.

A horse affected with glanders, may inoculate himself, and thereby produce farcy. Horses, when out at grass, are frequently affected by an itching, and are apt to bite their heels, when the flow of matter from the nostrils inoculates them, and produces farcy. The possibility of this circumstance taking place may be easily proved by inoculating a glandered animal in any part of his body with some of his own matter. There are many ways in which a sound horse may be accidentally inoculated with the matter of glanders, for the slightest scratch in any part of the body is sufficient. Horses that are cleaned with a curry-comb, are very liable to be scratched in those parts where the bones are most prominent; such as on the inside of the hock, the knee, and on the shank-bones. To such scratches glanderonious matter may be applied even by the hands of the groom, after he has been examining the nose of a glandered horse, or wiping off the matter from his nostrils. It may, also, be done by the horse himself transferring glanderonious matter from the nose of a diseased animal, or from the manger, or other part where any matter has been deposited; for horses are very fond of rubbing their noses against the manger or stall; and a glandered animal will generally rub off the matter from his nose against the manger, the rack, the stall, or against another horse. If a sound horse happens to stand by one that is glandered, they will often be seen nabbing, or gently biting each other, or rubbing their noses together, when glanders to the sound one may be the result. In short, when we know that glanders is thus communicated, we can conceive a variety of ways in which a horse may be accidentally inoculated. On one occasion, at the Royal Veterinary College, two grooms, who had the superintendence of the glandered stables, became, themselves, affected with the disease, and were obliged to be removed into an hospital.

When a horse has been twitched, he gene-
rally rubs his nose and lips with considerable force against the manger, and may thus easily inoculate himself with a glandered splinter or nail. The parts where the local fancy first appears, are those most likely to be accidentally inoculated; namely, the inside of the hocks, the knees, the shanks, the lips, and the under-jaw, where grooms are often trimming off the long hair with sharp-pointed scissors, or singeing with a candle, and causing an itching, which makes the horse rub the part against the manger. In this way the heels frequently become wounded. Horses that are kept on grains, bad hay, or any kind of bad provender, are liable to itching humours, which make them nab or bite their skin, and scratch the hind leg with the opposite foot. We may often see them bite, rub with the nose, and alternately scratch with the hind foot, the other leg. Even after inoculation, a month may elapse before the disease makes its appearance; and in all experiments for the production of glanders, some days, at any rate, will elapse before any ulcer or chancre is produced. It will be a week or two before fancy-buds or corded lymphatics will appear; and in some cases, probably, a month before the running from the nostrils will come on, except when a young ass is the subject of experiment. If we reflect upon all these circumstances, there will be no difficulty in admitting the following conclusions, in reference to glanders—namely: That glanders is a contagious disorder, communicable by inoculation, or by the effluvium proceeding from a glandered animal, that may have been kept in a stable with others, which, from weaker constitutions, have greater susceptibility to be affected by the disease, than others of a more robust and strong constitution. It has been also asserted by some clever veterinarians, that swallowing a quantity of the matter made into balls will produce the disease; but this we never found to be the case, as we have tried it in several instances, both on horses and asses. In doubtful cases—that is, when there is much difficulty in determining whether the discharge from a horse’s nostril is glandorous or not (and such cases frequently occur)—he should be removed to a stable, to remain by himself. Then purchase an ass, which may always be obtained for a few shillings, and inoculate him with some of the glandered matter. We have generally done this in the inside of the fore leg, on the plate-vein; and in two or three days, ample proof will be afforded, in the actual condition of the horse, whether your judgment be correct or not. We recommend this plan, because a valuable horse may be preserved at the expense of a few shillings. If the matter is really glandorous, a peculiar kind of sore or chancre will be produced. From this ulcer, corded veins, as they are termed, will proceed, and fancy-buds, or small tumours, will take place. In about a week the animal will run at the nose, and, in a short time, take on all the appearance of complete glanders.

In such a case, the disease is always very rapid, and always proves fatal. If the matter is not glandorous, no effect will be produced by it. In large establishments, where many horses are kept, this will be found a valuable test for determining with certainty the nature of a discharge from the nostrils. However mild the glanders may be, and although ulceration of the nostrils cannot be seen, and the quantity of matter that may be discharged is small, and the animal appear in good health and condition, the ass will be as certainly affected by the matter as if the disease were in the last stage, or in its most virulent degree.

For the sake of those gentlemen and agriculturists who may reside at some considerable distance from a regular veterinary surgeon, we will describe the method of performing the operation of inoculation.

Cut off a little hair to the size of half-a-crown, from the inside of the fore legs, where you can feel the vein. We prefer this part, because we have found the poison act quicker when injected here than in any other place, it being immediately on a large vein, which renders the communication of the poison to the system more expeditious. Then take a lancet, and introduce it under the skin, for about three-quarters of an inch in length. The orifice must be wiped free from the few drops of blood which may make their appearance. Have ready lint or tow that has first been well impregnated with the glandered matter, and introduce it into the opening with a probe, or small slip of wood. This being done, make a small wadding of tow, and place over all. Apply a bandage to the part, to keep
in the lint, and let it remain for a few days, and patiently wait the result.

If the matter is glandrous, the part will become excessively sore in about two days, and a scab will form on it. This, in a short time, will be thrown off, leaving a peculiar kind of ulcer, which will often spread rapidly, causing a painful swelling of the adjacent part, with corded veins, or facry-buds. After this, glanders will soon appear. No other matter will produce such an effect; showing at once the nature of the disease.

When colts are kept at grass, as they generally are, until three or four years old, they will have passed through a disease by which the whole constitution appears to be depurated, and consequently becomes invigorated. This is called strangles, which most frequently occurs when colts are kept on poor pasture, and which debilitates the animal to such an extent, that it often degenerates into glanders. While the colt is at grass, and kept well, the disease generally runs its course without much inconvenience to the animal, and without requiring the interference of art; but when he is taken up, broken-in, put to work, and kept in hot stables, and meantically fed upon hard and stimulating food, before strangles has taken place, a horse has often this disease with great severity.

Sometimes strangles comes on, and does not pass through its course in the natural way; the swelling under the jaws does not suppurate, or become an abscess, but remains hard; or a superficial opening takes place, from which a small quantity of matter is discharged, and this is sometimes supposed to degenerate into glanders.

This kind of glanders often terminates in consumption. It is accompanied with cough, and the discharge is generally from both nostrils, and more like pus than the matter which comes from the real glanders arising from contagion. From its not being contagious, however, it should be distinguished by another name. We would restrict the term glanders to those discharges from the nose which are capable of communicating the disease to other horses. This would be found highly useful in practice.

We now come to the consideration of the most difficult part of this subject, namely, the cure of glanders; and it is needless to say anything of the mode of prevention beyond observing, that this can only be accomplished by taking care that no glandrous matter comes in contact with the horse, or mixes with his food or water; and that the only method of purifying an infected stable is, to remove everything on which glandrous matter may have fallen, and to thoroughly wash and scrape the fixtures, such as the rack and manger. The stable should be well whitewashed, and the straw strewed with a solution of chloride of lime.

We have observed that glandered horses have, in several instances, been known to get entirely free from the disorder while employed in moderate work, and carefully fed and attended to, with little or no medicine. The general opinion of both English and French veterinarians, we believe is, that glanders is incurable, but that facry is curable. During an extensive experience, we have succeeded in curing many cases of facry, when it has been a local disorder; but such cases are generally followed by glanders, although there has been often a considerable interval—from a few weeks to a few months—between the disappearance of the one, and the appearance of the other. When glanders and facry appear at the same time, or when facry breaks out in a glandered horse, it would depend upon the state of the blood, as to its impregnation with the glandrous poison, whether we should recommend him to be immediately destroyed. We would, however, make an exception to this where a glandered horse has inoculated himself. Then the facry is at first only local; but as it soon becomes a fresh source of contamination, and, in a short time, increases the disorder, it always becomes necessary to destroy the animal. The cure of glanders cannot be accomplished without great care and considerable expense; and rarely at all, we believe, except in its first stage, or mild form.

The expense of the cure does not depend so much on the sort of medicines employed, as the length of time that is necessary to effect it; and it also must be recollected, that in saying the disease is curable, it is by no means to be understood that there is a certainty of success in adopting any mode of treatment. Therefore, unless the horse is of considerable value, in good condition, and glandered only in a mild
degree, it is not worth while to attempt the cure. It should also be recollected, during the treatment, that so long as there is any discharge from the nostrils, there is danger of its communicating the disease to other animals. Calomel has been tried, even to salivation, without the desired effect; also, Ethiop's mineral, or quicksilver rubbed down with chalk; but these are fallacious, and we may say, useless. Tonic medicines, and those principally of the mineral kind, have been resorted to; and the present practice of the Royal Veterinary College, for this disease, is to administer certain quantities of sulphate of copper. This was formerly done in balls; but it is now found much more convenient, and we believe is more beneficial to the animal, to be exhibited as follows:—

- Sulphate of Copper, from 2 to 5 drachms.
- Linseed Meal . . . . 1 oz.
- Warm Water . . . . 6 do.

Dissolve the sulphate in warm water; then add the meal, stirring them well together, until incorporated. Give this draught every morning.

We have seen some good effects arise from this, when the horse has commenced with it in the early stage of the disease; but when the disease has got a firm hold of the lungs, it is of little or no avail. We have succeeded in several cases, when advised of the state of the animals in time, by giving the following, either in form of a ball, or a solution, as in the last:—

- Sulphate of Iron . . . 3 drachms.
- Gentian . . . . 3 do.
- Form into a ball with treacle.

It is better to give this in the form of a ball; whilst the horse should be turned out into a pasture of grass by himself, to prevent all possibility of his coming in contact with any other horses. If possible, a warm shed should be in the paddock or field. Give the ball about the middle of the day, and, every night and morning, a feed of good oats and beans. By turning the animal out, he will breathe the natural air, not respiring his own over and over again, as if in the stable. Then, by the tonic medicine and good feed, if he is of any constitution at all worth the expense, it will be found that this is the only practicable means of removing glanders. Constitution has so much to do with the disease, that if well supported by art, these are the only means to be adopted. We should say, never treat a horse affected with glanders in a stable. The horse, also, by hanging down his head to gather his food, relieves himself, and the discharge comes more freely from him. However, practice and experience in the treatment of this disease, must be the leading features for obtaining a knowledge of it.

CHAPTER XXIX.

EPILEPSY; PALSY; SPASM; COLIC, OR GRIPE; TETANUS, OR LOCK-JAW; STRING-HALT.

EPILEPSY.

The affection termed epilepsy, frequently affects cart and waggon horses more than any other kinds; and in different counties and localities, it assumes a variety of names, such as meagrinus, sturdy, turnsick, the falling-sickness, the falling-evil, &c. The affection, in its first attack, comes on suddenly, and without any previous indications. The animal, if in exercise, stops short, shakes his head, and looks wandering; in which state he continues a short time, and then will go on as before. If the case should be a violent one, he frequently falls to the ground, or commences turning round and round, until he drops apparently senseless.

The whole system appears agitated by strong convulsions; he dung and stales insensibly, at times becoming exceedingly violent; at others, appearing as if life were extinct, unconscious to everything around him; his eyes seeming fixed, and often his jaws
are so closely set, that his mouth cannot be forced open. At other times he labours under convulsive motions, and his limbs shake so violently, that he even breaks the pavement with his feet, if he fall in such a situation. Sometimes, while the legs are still, the head and body are violently agitated. These varieties of symptoms frequently attacking him alternately, it is not to be wondered at that the affection should remain on him, in some instances, two or three hours, more or less, and then that he should recover, sometimes without any return of it; at others, the fits are more or less troublesome, according to the success of the means applied for relief. As the fit goes off, there is generally a foaming at the mouth; the foam being white, and resembling that of a healthy animal.

The causes of epilepsy are several. It appears to be dependent on a kind of epascular affection of the brain, either from too tight reinving up, or the collar pressing too hard. It may also arise from blood being forced to the head by constitutional disorders. Worms is a cause of it. Horses of very full habit, plethoric, or over-fed, are liable to it, particularly when not having constant exercise.

For the curative means for epilepsy, nothing can be done while the horse is enduring the fit but the following, which will be found excellent:—

Strong Liquor of Ammonia . . 1 oz.

While the convulsion, or fit, is on, hold the bottle of ammonia frequently to his nose; and in all probability he will immediately jump up, or, at least, in a very short time, with the fit driven from him. Should he be a large cart-horse, in high condition, take four or six quarts of blood from him; feed him on cold bran mash, and give a dose of physic or two, according to his strength or size. The mercurial ball, composed of blue pill and aloe, is also very good in this case. If it can be procured, occasionally feed with grass; but hard food must be lessened. We have seen some poor farmers' horses attacked violently with this disease, and have attributed it to the excessively hard and bad arrangement of the harness with which they were furnished. Therefore too much care cannot be bestowed on the gearing with which a horse is caparisoned.
to the least deserving part of it. The farrier says, “It was my change that restored the horse;” leaving rest and Dr. Green completely out of the question. In India there is a disease called kuweree, which always ends in complete paralysis of the hind quarters. Most of the horses used in that country are stallions; and these are the subjects that become affected. We never saw it in a mare or gelding, with the exception, that the horse, on the commencement of the attack, had gone through the operation of castration, which is imagined to be a remedy for it; but we never found one cured by this, or any other remedy; for the horse will continue getting worse and worse, until he is unable to rise at all, and is consequently destroyed.

**SPASMS.**

*Spasm* is an irritability of the muscular fibre, excited by an action of the nervous system, producing various affections, known under the general name of spasm, but subdivided according to the part affected with this excitement. When universal, it forms *tetanus*; when confined to the bowels, it forms *gripes*; and when it attacks the neck of the bladder, obstruction to the urine follows. Inflammation of the sensorium, or of the nerves, or of the investing membranes of these organs, can produce this excitement. Thus, in phrenites, the horse is excited to exertions much beyond his usual powers. Irritation occasioned by foreign substances can also produce it; perhaps, by exciting an immediate inflammation, although the instantaneous spasm which follows mechanical pressure and irritation, both in the sensorium and the nerves, can scarcely be accounted for thus.

In medical treatment, sedatives act either by allaying the nervous excitement, or relaxing the part affected with spasm; such as opium, tobacco, &c.: antispasmodics, also, by rousing the heart and arteries to a new action; as gin and pepper, spirit of turpentine, rendering the part above or below the disposition to be excited. In very violent cases of spasmic affections, copious bleeding, combined with solutions of aloe and opium, are powerful antispasmodics. In the spasmodic state of the neck of the bladder, nauseating medicines are found to be the best antispasmodics; such as digitalis, or white hellebore. The remedies which act by altering the susceptibility of the parts, are principally bleeding, purging, or clysters, and other evacuants, which diminish the excess of power; and are, therefore, extremely proper in plethoric subjects, or when the spasm is attended with great vascularity. When, on the contrary, the spasm attacks a subject already in a debilitated state, recourse must be had to the stimulant remedies, to bring the part to a state to resist the impressions. (See List of Medicines).

**SPASMODIC COLIC, OR GRIPES.**

*Spasmotic colic* is, amongst agriculturists, known as *fret gripes*, &c. Although it is termed flatulent, or windy colic, wind is not so predominant a symptom as it is in the human subject. The small intestines seem more the situation of spasmotic colic than any other part of the horse; but there are instances where the large intestines have become affected; and when it proceeds so far back as the rectum, the bladder then also participates in the convulsion, and frequent ejections of urine occur. In other instances the neck of the bladder suffers, and suppression of urine then becomes remarkable; but these are only in extreme cases. Colic is dependent on a spasm of the muscular structure of the intestines. We have evident proof of this from the appearances which present themselves after death, where cases have proved fatal; when the small intestines, more especially, will be found puckered and drawn together; or some portions will afford marks of violent contractions, as though they were tied round with a cord. Occasionally we find an interception, or one portion of intestine invaginated within the other; in which case inflammation is usually brought on by it.

Spasmotic colic, however, generally exists without inflammation, though it frequently terminates in it, when suffered to have a long continuance, from there being no speedy remedy at hand, or no surgeon living in the neighbourhood to administer proper relief. Rubbing the belly with a hard stick, &c., should, on such occasions, on no pretence whatever, be done. Powerful purgatives to overcome the costiveness, usually present, frequently have this tendency; but a still more frequent cause is the invagination of one por-
tion of intestine within another. In attending to the medical treatment of colic, care should be taken that it is not confounded with inflammation of the bowels; the remedies for each of these diseases being diametrically opposite to each other.

Spasmodic colic generally makes its appearance very suddenly, and is not marked, as in inflammation of the bowels, by previous indisposition; the horse, being, at once, attacked with considerable uneasiness, shifting his position from side to side, pawing the ground, and stamping with his feet, impatiently and violently.

In a few minutes after this, the pain will appear to go off, and leave the animal tolerably easy; but in inflammation of the bowels, the pain constantly occasions the stamping, and it does not pass away, even for the shortest space of time. As the colic proceeds, remissions of pain become less and less. The horse lies down frequently, and, on rising, shakes himself, looking anxiously round to his sides, and sometimes, in desperate cases, even biting at them, or snapping at them with his teeth. He also strikes at his belly with his hind feet, as if determined to remove his sufferings himself. In inflammation of the bowels, the above symptoms are seldom so severe, the pain not being so great. When on the ground, he frequently rolls on his back; in which situation he will remain four or five seconds, or probably roll over; neither of which he does in simple inflammation.

The pulse is the next thing to command attention, which, in colic, seldom becomes much altered from its natural state, unless the affection has existed some considerable time, when marks of general irritation sometimes present themselves; the pulse being somewhat hardened and quickened. Occasionally, when the paroxysms are on, a slight alteration may then be felt; also in the early stages, should the pain be great; but slight alterations come and go as the pain passes off.

If the horse is under the immediate influence of existing spasm, he will, in some instances, present a full bounding pulse, but oftener a wiry, though quickened beat; both of which may be taken for inflammation. The legs in colic are but seldom affected, and never remain cold for considerable periods of time together; but the coat stales, and the horse breaks out frequently into cold sweats. He often attempts to stale, without effect; at other times he stales frequently. Generally he is costive; a few dry balls only being forced from him during the spasmodic fits.

Spasmodic colic is produced by cold supervening on heat, either through the medium of application to the skin, or by sudden application to the bowels, in the form of cold water, taken when the horse is very warm. Costiveness will sometimes occasion it, through improper food; also tares, or vetches, given on their being first cut. When they are full of moisture, the animal is apt to eat greedily of them; and especially if the weather is warm.

In some, gripes are frequent, under every variation of food, situation, habits, &c.; so as to give reason to suppose there must be some peculiarity of formation, hereditary tendency, or the presence of calculi in the intestines of such animals as are subject to them.

For the cure of gripes, we should recommend bleeding, more or less liberally, according to the violence of the disease, or its longer or shorter duration; or its continuance, without mitigation. Extensive bleeding is one of the most powerful relaxers of spasm with which we are acquainted; and, instead of its being an antagonist to the antispasmodic treatment, usually adopted by internal remedies, it is found to be infinitely increased in efficacy; and especially when conjoined with opium. Though most of the ordinary cases of gripes will pass away with the common treatment of stimulants, and many go off without any treatment at all, yet bleeding is always a safe and prudent precaution, as a preventive of inflammation; and, in more aggravated cases, it becomes essentially necessary, both to combat the inflammatory tendency, and to promote the relaxation of the spasmodic irritation. It is likewise particularly to be noticed, in violent or protracted cases, to counteract the irritative qualities of the anti-spasmodics, which, in simple gripes, may do no harm, yet may do so when an inflammatory tendency is at all suspected, or already begun. In every such case, bleed liberally; say, at least six quarts; which, if the horse is in anything like moderate condition, cannot do harm.

We have known horses bled in the mouth for
locked-jaw.]  

THE HORSE, AND [locked-jaw.]

gripes; but never saw any good arise from it. Giving the animal a brisk trot for about a quarter of an hour, after either of the following remedies, we have proved to be exceedingly beneficial; but he should never be made to go faster than the trot. Brushing the belly well will be of service; but never rub it with a stick, as this tends to bruise the parts, more than to do good. We have known the turpentine liniment, rubbed well all over the abdomen, to be a great assistant in removing the spasm. Hot fomentations we do not approve, as the water that may lodge in the hair, when it becomes cold, will frustrate all good intentions.

As internal remedies, either of the following will be found very efficacious in removing the disease:—

No. 1.

Ground Black Pepper . . . . ½ oz.
Tincture of Opium . . . . 1 do.
Good Ale (warmed) . . . . 1 pint.

No. 2.

Common Gin . . . . ½ pint.
Tincture of Opium . . . . 2 oz.
Good Ale (warmed) . . . . 1 pint.

If costiveness should be present, give—

No. 3.

Oil of Peppermint . . . . 2 drachms.
Castor Oil . . . . 6 oz.
Tincture of Aloes . . . . 4 do.

Should the costiveness continue, the horse must be back-raked, and warm clysters administered, with a handful of salt thrown in each, about three quarts at a time, until the bowels are relieved. Should other means of assistance not be ready at hand, give the following:—

Ground Black Pepper . . . . 1 teaspoonful.
Common Gin . . . . ½ pint.
Good warm Ale . . . . 1 do.

Should the disease continue longer than may have been expected, repeat the remedies until relief is obtained. If the clysters should not have the desired effect, take a large onion, peel, and quarter it, and pass it up the rectum, which will speedily stimulate it to action.

TETANUS, OR LOCKED-JAW.

Tetanus, or Locked-jaw, is a violent spasmodic contraction of the muscles, coming on in the elevation of the lower jaw, and extending, more or less, to all the muscles destined to perform voluntary motion. This disorder, which may be excited by different causes, is much more common in hot climates than in temperate. However, it too frequently occurs in this country, and happens to be one of great difficulty to cure, especially in consequence of wounds; and more particularly after injuries of tendons and ligamentous parts. It is one of the most fatal symptoms which can possibly arise in these cases, and therefore demands the most assiduous attention of the veterinary surgeon.

Tetanic complaints generally affect middle-aged, or old horses, more frequently than young ones. The causes producing them are cold and moisture applied to the body while it is very warm; and sudden vicissitudes of heat and cold; or they may be produced by punctures, lacerations, or other lesions of nerves in any part of the body. There are, probably, some other causes of this disease; but they are neither distinctly known, nor well understood. If the disease proceeds from cold, it commonly comes on in a few days after this being taken; but if it arise from puncture, or other lesion of a nerve, the disease does not come on for many days after the lesion has happened—very often, when there is neither pain nor uneasiness remaining in the wounded part; and very frequently when the wounded part has been entirely healed up. The disease sometimes attacks suddenly, with great violence; but, more generally, it makes its approaches by slow degrees to the violent stage. In this case it comes on with a sense of stiffness in the muscles of the neck, which, gradually increasing, renders the motion of the head difficult and painful. The haw of the eye, also, will be seen protruding, on the least motion of the head being raised towards the head.

As the rigidity of the neck increases, there is commonly, at the same time, a sense of uneasiness felt about the root of the tongue, which, by degrees, causes a difficulty in, and, at length, an entire interruption of swallowing.

While the rigidity of the neck goes on increasing, there arises a pain, often violent, at the lower end of the back, which makes the tail stick out with a quivering motion. When this pain arises, all the muscles of the neck,
and particularly those of the upper part of it, are immediately affected with spasm, as it were, drawing the upper part of the head violently and strongly backwards. At the same time, the muscles which draw up the lower jaw, and which, upon the first approach of the disease, were affected, are now generally affected with more violent spasm, and set the teeth so closely together, that they do not admit of the smallest opening.

This is what has been named locked-jaw, or tetanus, and is often the principal part of the disease. When it has advanced thus far, the pain at the top of the neck and lower jaw is renewed with violence. As it proceeds, a greater number of muscles become affected with spasm. After those of the neck, those along the whole of the spine become affected, bending the trunk of the body strongly backwards, whilst the horse keeps his fore legs stretched directly out before him.

At the extremities, both the flexor and the extensor muscles are commonly at the same time affected, and keep the limbs rigidly extended. Though the extensors of the head and back are usually the most strongly affected, yet the flexors, or those muscles of the neck which pull the head forward, as well as the muscles which should pull down the lower jaw, are also, often at the same time, strongly affected with pain and spasm. During the whole of the disease, the abdominal muscles are in a violently spasmodic state, so that the belly of the horse is strongly contracted, and feels as hard as a piece of board.

At length, the flexors of the head and trunk become so strongly affected, as to balance the extensors, and to keep the head and trunk almost in a straight line, and so rigidly extended, that they are incapable of being moved in any way. It is to this state the term tetanus has been strictly applied.

At the height of the disease, every organ of voluntary motion appears to be affected, and amongst the rest, the muscles of the face. The eyes also seem distorted, commonly rigid, and scarcely movable in their sockets. The nose also appears drawn up; and the spasms are, everywhere, attended with most violent pain. The utmost violence of spasm is, however, not constant; but, after subsisting a minute or two, the muscles admit of some remission of their contraction, although of no such relaxation as can allow the action of their antagonists. The remission of contraction gives also some remission of pain; but neither is of long duration. The attacks of the disease are seldom attended with any fever. When the spasms are general and violent, the pulse is contracted, hurried, and irregular; and the respiration is affected in like manner. The heat of the body is commonly not increased. The extremities are generally cold, with a cold sweat over the whole of the body. Blood is frequently drawn in this disease; but it never exhibits any inflammatory crust; and all accounts seem to agree, that the blood drawn is of a looser texture than ordinary, and that it does not coagulate in the usual manner. It is no less extraordinary, that in this disease, the natural functions are not either immediately or considerably affected; and it is usual for the appetite of hunger to remain through its whole course.

This disease frequently follows docking and nicking; it has also been known to occur after castration.

To cure tetanus is very difficult. So many remedies have been tried, and so many failures arisen, that there can be no certain remedy pointed out for the removal of so distressing an affection. The cold bath had, for a long time, its advocates; but without any real good. If one horse got well under such treatment, it was applied to all, but not with general success; consequently, it fell into disuse. Bleeding, as a relaxant to the spasmodic action of the muscles, has also shared the same fate. Blistering the whole course of the spine has met with no better success. Even the old farrier's remedy, of docking the tail about an inch, does not seem to carry a specific with it. Unions, balsamic, and spiritual embrocations, which many practitioners have recommended, are not only useless remedies, but even hurtful. If the case arise from a wound, a local inflammation ought to be excited in the wounded part itself, and the inflammation roused as high as may be consistent with the resolution afterwards. We certainly know that nothing promotes a general phlogistic diathesis through the system more than a wound, attended with a high degree of inflammation; but this is not always to be obtained,
THE HORSE, AND

[INFLAMMATIONS.]

though the strongest stimulants the whole list of medicines could produce may be applied; for we have found that in wounds productive of inflammation, there is an absolute want of this inflammation, so necessary to the cure and well-being of the patient. To obtain this inflammation, the best thing to do is to enlarge the wound as much as may be convenient, and insert a pledget of tow, dipped in warm oil of turpentine.

We have restored a horse from tetanus by a strong solution of aloes, combined with laudanum, as under:—

Spirituous solution of Aloes . . 3 oz.
Laudanum . . . . . . 1 do.

Give this mixture frequently; say every three hours. If the jaws are so closely set that it cannot be given to the horse by the mouth, have his head elevated by force, and pour the mixture into a quart bottle; then carefully pour it down one of his nostrils; which, after a little time, he will not resist. When he has begun to take the above without much difficulty, break a little of the cordial pectoral ball with it. Continue this until you see a change for the better; which will be known by the jaws becoming loose, when a favourable termination to the disease may be expected. Give clysters the whole of the time you are exhibiting the medicine. We have administered prussic acid; but never with any good effect. We have also administered brandy, with the cordial pectoral ball dissolved in it, with good effect. In conclusion, we should never give a case of tetanus up, until we have tried every means possible.

STRING-HALT.

String-halt is an involuntary and convulsive motion of the muscles, which either extend or bend the hock; principally considered in the superficial muscles, or the facia lying on the inside of the thigh, and causing the horse to twitch up one or both his hind legs in a most remarkable manner. Strains and blows are the causes to which this disease is generally attributed. We once were called to a horse that had been cast into a ditch, and we were obliged to employ ropes to extricate him. He had struggled very hard whilst in the ditch, but, when released, he had the affection of string-halt in the leg that was underneath. A cure is seldom effected. We have known soap liniment, well rubbed on in the inside of the thigh, to relieve the disease; but never saw a perfect cure. On some parts of the continent it is considered a graceful movement when in both legs.

CHAPTER XXX.

INFLAMMATION OF THE BRAIN, OR MAD STAGGERS; INFLAMMATION OF THE STOMACH, OR STOMACH STAGGERS; INFLAMMATION OF THE LUNGS; PULMONARY CONSUMPTION.

INFLAMMATION OF THE BRAIN, OR MAD STAGGERS.

Mad Staggers is one of those diseases which, happily, seldom affects the horse; and it is fortunate for the poor animal that such is the case, for the pain arising from it must be intolerable. This disease, like many others has acquired various names, constituting, in former practice, a variety of different diseases; though by the advancement in veterinary science, they have all been nearly reduced under two heads. These names were applied to such disorders as principally affect the head, having their seat in the brain, or vessels leading thereto; such as apoplexy, convulsions, epilepsy, stag-evil, frenzy, or fever, &c., &c.

Mad staggers, or inflammation of the brain, may be defined as being a determination of blood to the brain, causing considerable pressure on that organ, as well as on the vessels leading to it. How far the pretended accuracy, formerly distinguishing one of these
diseases from another, may be appreciable by
modern comprehension, or receive general
credit; we know not; but confess, where the
judgment has to be formed from observation
alone, made by a close scrutiny of the
patient, circumstances very seldom so far
concur as to enable us to form so singular a
distinction. Experience and observation may,
undoubtedly, do much, in a collection of simili-
tudes and probabilities, but never sufficient to
enable us to ascertain the distinct, invariable
causes and effects of diseases, where the most
trilling difference is hardly acknowledged.
More particularly is this the case when it is
considered that the cause of all these disor-
ders is in the original seat of nervous irrita-
bility, the brain; or in those parts connected
with, or dependent on its structure and purp-
oses; except when the diseases are under-
stood to be symptomatic, or dependent upon
some original remote cause—as the effect of
bots, preying upon the stomach or intestines,
internal ulcerations, or complaints not imme-
diately discoverable. These may sometimes
happen, but very rarely, to affect the frame
with symptoms truly alarming.

Horses, upon the approach of any of those
disorders whose seat is directly in the brain,
or nervous system, display considerable weak-
ness and inactivity; seeming to move reluc-
tantly, reeling, or staggering in their walk;
frequently blinking with their eyes, as if their
vision were imperfect, and feeling some dis-
greeneal impression, or uneasiness, from the
effect of light. They are also much averse to
being handled about the head, and are brought
out of the stable with difficulty. In time, a
visible tremor comes on; and, after reeling, or
frequently turning round, if loose, they fall
almost lifeless to the ground, having only the
perceptible power of breathing with violence
and agitation.

Horses affected with staggers have a disin-
clination for food of all kinds. They have also
a slight discharge of moisture from the eyes,
which, if attentively observed, even in the
earliest stages of the disease, will be found
inflamed, and somewhat flushed in colour.
Hence the blinking of which we have spoken.
The nostrils also may be observed redder than
usual; but this is not always a true symptom.
As the disease advances, the horse appears im-

patient, and throws himself about in a most
extraordinary manner, as if he were frightened;
or he falls into a drowsy state, holding his
head low, and resting it on the manger.
Then, all of a sudden, he will commence
throwing himself about again. If the disease
should not be speedily alleviated, but continues
for a day or two, he will exhibit a kind of
vacant stare, or watchfulness; the eyes will
appear set, as it were, in the head—their sight
almost gone; his nostrils expanded, his head
raised as high as he possibly can, as if staring
at the rack. He now becomes more furious
and violent; dashes about the pavement in
convulsive and insensible struggles; perhaps,
falls, then suddenly rises again, to renew his
violence.

Diseases originating in the most abstruse
recesses of nature, though of a very com-
plicated construction, may proceed from a
variety of causes, clearly comprehended; as, in
all probability, they may likewise do, from
many that we are entirely unacquainted with.
Among the former is that which originates
in the increase of the velocity of the blood,
instantaneously affecting the brain, as we find
when we exceed the bounds of humanity, and
exhaust the strength and power of an animal,
made by nature sufficiently strong to accom-
plish almost every task the ingenuity or
avarice of man might be supposed to invent.
In corroboration of this, the premature deaths,
occasioned by increasing the velocity of the
blood beyond the limits prescribed by nature,
extend principally to post-horses, in the ex-
treme heat of summer; and may be attributed
to the impatience of travellers, or inhuman
drivers.

To these, some, but very few, private horses
may be added, being hard driven upon long
journeys; and others, imprudently ridden and
improperly managed during chases of great
length, in strong deep countries, with fleet
hounds.

Others become the subjects of these disor-
ders, from great irritation in the stomach and
bowels; the powerful effects of bots in the
intestinal canal; sharp and acrid medicines; a
repulsion of any morbid matter from the sur-
face, without its being carried off by proper
evacuants, &c. They are frequently known
to attack very suddenly; at other times their
Inflammations]

The Horse, and

[Inflammations]

Approach is indicated by the symptoms before recited.

The most rational method of cure for these diseases is, by correcting or discharging the primary cause, which will be to allay the spasms, and to reduce the extreme degree of irritability, by strengthening the nervous system. To obtain this end, the first step will, at all events, be to draw blood, the quantity to be regulated according to the state of the subject. In cases of real alarm and danger, take from six to eight quarts away at once; and we have seen much relief obtained in bleeding from the jugular vein, and the thigh vein, both at the same time. It causes a greater revolution in the system, although it becomes absolutely necessary afterwards to stimulate and rouse the animal powers. As little can be done during the time of the fit or paroxysm, prepare a clyster of warm water, in which a handful of salt should be put, and given as soon as possible.

Should spasms or convulsions prove so violent, that by a contraction of the muscles the jaws become locked, or fixed for any considerable length of time, recourse must be had to nutritive clysters, that the constitution may be supported. Notwithstanding its inability to receive aliment by other means, there are several kinds of nutritive clysters, that may easily and expeditiously be prepared, consisting of broths of different kinds, which most houses have in readiness. Oatmeal gruel, in which a little starch has been mixed, is an excellent strengthening clyster. These clysters should frequently be given, until a ball can be safely administered. If the mouth be not sufficiently open to admit of the hand being safely introduced, take one of the cordial restorative balls—see List of Medicines—and dissolve it in about a pint of warm water, and carefully horn it down. This will rouse the system from the debilitating effects of the spasms.

If the horse is not sufficiently relieved, but still keeps drowsy, and inclines to hang his head down, or bear against anything, as it were, for a resting-post, immediately bleed again from the opposite jugular vein, and also from the opposite thigh-vein, taking as much blood away as he can possibly bear. Then take of

Tartar Emetic . . . 1 drachm.
Hog’s Lard . . . 1 oz.

Form into an ointment, and rub the whole at once on the forehead. This will cause pimples to rise, which will speedily relieve the brain.

Should any local paralytic affection, or contraction of the muscles, produce a stiffness or inactivity upon any part, recourse must be had to friction, with penetrating embrocations; for, during the paroxysms of the disease, the animal is so liable to injure himself locally, that it is necessary to use stimulating applications to remove the bruises, &c., that he may have received. For this purpose take

Oil of Tar . . . . 4 oz.
Oil of Turpentine . . . 2 do.
Spirits of Wine . . . . 2 do.

Mix, and apply to the parts affected, night and morning. This must not be negligently done, and should be persevered in for twenty minutes at each dressing.

Horses of a full plethoric habit, when attacked with this disease, should, as soon after recovery as they are able to bear it, be brought under a course of regular evacuations; such as are most applicable to their size, state, constitution, and condition. If they are inclined to fluctuating humours, or viscid heavy foulness, give one or two purging-balls, according to strength, &c., as before remarked. (See List of Medicines). If purgative medicine should be considered too strong, change it to alternative, which will act more mildly, and have a good effect. Give, at the same time, soft food, as bran mashers, or mashers with a little corn in them.

If the disease should have arisen from worms affecting the stomach, administer the mercurial purging-balls; for which, see List of Medicines.

Inflammation of the Stomach, or Stomach Staggers.

Stomach staggers is a disease to which many horses fall victims; few, or rarely any, recovering from the effects of its attack. Generally speaking, it almost always proves fatal; and although many practitioners have boasted of being possessed of a remedy, and although many cures have been said to have been effected by them, such cures have not taken place in what may be denominated stomach staggers. In examining horses that have died of this disease, the stomach has been generally loaded with hard,
There is nothing except excessive exertion, perhaps, that does so much injury to the stomach as bad hay; and when these causes are combined, the most formidable diseases are produced, and almost all of them depend on the diminished energy of the stomach.

If we consider the important office of the stomach—namely, the preparation of food in order to form blood, and thereby repair the waste or wear which all the muscles are constantly undergoing—what can be expected when it is supplied with food that contains but little nutriment, and requires its utmost exertions in order to digest it? The excessive exertions in which horses are commonly employed in this country are sufficiently known. Custom, we fear, has so familiarised manyavaricious horse proprietors to these cruel exertions, as to prevent them from viewing the situation of the horse as they ought; and we frequently hear them boasting of their driving or riding an animal so many miles in a short space of time, as if the merit of the performance was due to them instead of to the quadruped. The stomach-staggers, however, is not so common as it used to be. We have known farmers absolutely ruined by the disease, from its having continued among their horses until all of them have been destroyed. The better feelings which have taken place among this class, and which are still spreading, render diseases among their horses far less frequent than they used to be. A concurrence of the causes before noticed—that is, excessive exertion and improper feeding—were wont to be most frequent amongst post and stage-coach horses; and it is here that diseases of the digestive organs are oftenest to be met with. Stomach-staggers, however, is not the symptom that occurs; it is one of a different description; that is, flatulent colic, or gripes. The condition of the stomach, which produces this, is exhaustion of its vital power; differing from that which produces stomach-staggers, not only in degree, but also in kind. In stomach-staggers, the power of the stomach is so gradually diminished, that the disorder almost imperceptibly takes place, and is rarely observed until it is incurable. In the other, the disease is more rapidly developed, and therefore the effect is different.

In most instances this disease has termi-
nated fatally, in consequence of medical advice not being called in early enough, and its ravages suffered to go on until the animal is irrecoverable; but even if the veterinarian is called in early, he is frequently baffled in his attempt at a cure, let his abilities be ever so great; for, if he administer medicine in the shape of balls, they become completely neutralised, in consequence of the over-distention of the stomach, and the consequent inflammation set up. A draught, however, should be given as early as possible. Some writers have recommended a solution of aloes in large doses, but this we consider quite contrary to good practice; for, though the grand object should be to remove the contents of the stomach as early as possible, aloes would be most likely to debilitate that organ, and produce nausea; consequently it would be incapable of acting on its contents; for costiveness of the stomach and intestines cannot be overcome without acting on both, and that in a very different manner.

To overcome the one, use the following elyster:—

| Common Salt               | . . . | 8 oz |
| Tincture of Aloes         |       | 4 do.|
| Warm Water                |       | 2 do.|

Inject—after first back-raking—and hold the tail well down upon the anus, that the horse may retain the elyster as long as possible. Repeat this operation until the bowels are quite empty. At intervals, apply to the region of the stomach—

| Oil of Turpentine         | . . . | 4 oz.|
| Olive Oil                 | . . . | 2 do.|

Rub this well in; and should it not have the desired effect, repeat the quantity. At the same time give the following:—

| Common Gin                | . . . | 1 pint.|
| Tincture of Myrrh         | . . . | 2 oz. |
| Camphor                   | . . . | 1 do. |

First dissolve the camphor in the gin; then add the tincture. Give this new-milk warm. If the animal should not appear better in the course of an hour, repeat the draught. This will, in all probability, stimulate the stomach to a new action, to get rid of its contents. We have restored several horses by the above treatment; and, if taken in time, we question its ever failing. Everything having passed off agreeably, administer good gruel frequently; but give little or no hay, as that will tend to irritate the stomach in its weak state. Bran mashes, with oat or liniæed meal mixed in them, will be good enough; but refrain from giving corn of any kind, until satisfied he is perfectly recovered, as the least irritating food may occasion a relapse.

INFLAMMATION OF THE LUNGS.

This disease is one of the greatest difficulty with which the veterinarian has to contend, as it proves so frequently fatal. It was not understood by the older farriers, and consequently they administered hot stimulating drugs, which they conceived would banish or eradicate a disorder, which generally ended in death, until the establishment of the Royal Veterinary College, when a new system of practice was promulgated. The disease is now understood, and thousands of horses that would have been doomed to the dog-kennel, have lived to follow the chase; saying nothing of the numerous roadsters and hacks, as well as draught-horses, that have lived double their time, from the well-known knowledge and experience which have been diffused through the veterinary world during the present century. There is in the human subject a disease called pleurisy, which consists of an inflammation in the thin membrane which covers the substance of the lungs, which, being intimately connected with the substance of the lungs itself, and the cavity of the chest, has been thought to have been a disease of itself in the horse; but such is not the case. The pleura of the horse is seldom or ever the situation of the disease. If the pleura should be diseased in the horse, it is in connection with the substance of the lungs. Whenever the blood is prevented from circulating freely through the lungs, it becomes the origin of several other disorders.

Disease, it is well known, is not always sent as a punishment, but is intended by nature as a process by which the animal economy should be changed or restored; and nature provides many more forces than one, to remove a portion of all kinds of animals periodically. This law rules the vegetable kingdom also. But the diseases of horses mostly spring from their artificial life; and to none are they more subject than to inflammation of the lungs.

Against the symptoms of pneumonia, or in-
Inflammation of the lungs, it is necessary to guard the practitioner from mistaking them for those of catarrh, or of the mucous membranes in catarrh, with which they may be confounded; though the experienced veterinarian will readily distinguish between the two. In the catarrhal epidemic, the extremities do not continue invariably cold, but are sometimes cold and sometimes warm. The distress of countenance is not so great; sore throat is commonly present; breathing is less laborious, and the pulse seldom oppressed.

The cough in catarrh is generally deep, and very painful; a weakness, not corresponding with the violence of the symptoms, is very early seen in the complaint; and, though the lining of the nostrils may be inflamed in catarrh, it is seldom so much so, if pneumonia be coming on, as to present a purple hue. The principal necessity which exists for making a careful distinction between the two diseases, arises from its not being found prudent, in the catarrhal affection, to push the bleeding, and other parts of the depleting system, so far as in the pneumonic; and also from the greater necessity of placing the horse in a cool temperature in the latter, to what exists in the former. Inflammation of the lungs has, also, by the inexperienced, been occasionally mistaken for colic; because the animal sometimes exhibits considerable uneasiness, and often looks round to his sides; in which mistaken cases, the treatment generally pursued has been such as to increase the disease. But, in colic, acute pain is shown to be felt. By turns the horse lies down and rolls, and then suddenly rises, stamping with his fore feet, or kicking at his belly with his hind legs; while, in peripneumony he never lies down, but stands stupidly quiet, except now and then, when he may look at his flanks, but without any of the indications of pain to which he is forced by colic. It may be added, also, that the nasal membrane, in colic, remains unaltered in colour, unless inflammation of the lungs be at hand.

CAUSES.

The alternation of heat, with cold, is probably the most usual cause of this complaint. It was formerly considered that it could only be produced by removal from a warm to a colder temperature; but it is now known that the sudden access of a warmer medium produces it also, though certainly not to an equal extent. Exposure to simple cold has been said never to produce this disease; and, though turning horses to grass without preparation may emaciate them, it never produces peripneumony: but this appears not to be borne out by experience, and has occasioned ill consequences. Human subjects, horses, cows, sheep, and dogs, are all more liable to coughs, colds, and pneumonic affections, in cold than in warm climates. The persons who slaughter horses in London, are accustomed to expect a great number in the winter, especially if it is severe and frosty, from the fatal effects of inflamed lungs. Hunting on a cold scent, with frequent checks, or travelling with a cold wind blowing against the chest; washing the legs and body with cold water while the animal is hot; or sudden removal from a warm stable to a cold one—any of these may cause inflammation of the lungs, if great care is not taken; and, as has been remarked, the removal from a cold stable to a warmer one, or from grass to a warm housing, without preparation, may also produce it. In fact, so liable are horses to affections of the chest from a change of temperature—whether it be from a warmer to a colder medium; or otherwise, from a colder to a warmer—that it is very seldom a horse is brought from a dealer's stable, that does not, in a day or two, exhibit some cough. When he is removed from a cold temperature into a hot one, it is evident that the hot medium immediately attacks the seat of inflammation; and as hot air must tend to accelerate the circulation, it is not difficult to give a reason why it produces the disease, and this more certainly if the heated air is less pure than that which the animal was removed from. When, on the contrary, the removal takes place from a warm to a colder situation, perhaps a similar effect also takes place. The cold air immediately affects the lungs, which may, by its sedative properties, particularly if the change is very great, be suddenly weakened. But it is not only by application to the immediate cellular substance of the lungs, through the medium of respiration, that cold acts injuriously on them. It often exerts its baneful influence through the medium of the skin, with which these organs are connected by a sympathetic and peculiar
inflammations.]  

The Horse, and

[Inflammations.

union, and which is liable to be at all times exposed to the vicissitudes of temperature; for both skin and lungs appear emunctores of the fecal parts of the blood, and hence the sympathy between them is observed to be very great. Anything, therefore, that may prevent the exit of this fecal matter, called perspiration, from the vessels of the skin, will throw much more of it on the lungs. When, therefore, in addition to these occasional causes, we consider that the lungs are very large, as well as very important organs, and that in an animal of speed they are peculiarly extensive in their surfaces, and extremely vascular in their structure, we shall be at no loss to account for their tendency to inflammation.

This tendency, also, seems much heightened in common with the proneness to other diseases, by artificial life; for in a state of nature, or one nearly approaching to it, they are seldom attacked. Even cows experience this increased tendency, arising from artificial habits, as may be observed in those kept near London, and other great cities, where they are more artificially supported, and subjected to occasional housing.

Cure of Inflammation of the Lungs.—The principal modes of cure are two: first, to lessen the increased vascularity or distension of the lungs, by bleeding; and second, to endeavour, by external stimulants, to change the diseased action: that is, by raising an external inflammation, we try to lessen the internal one; and it must be remarked, that as this disease is obstinate and quickly fatal, so the treatment must be active and immediate. The cure should therefore be promptly begun by bleeding, according to the age, size, and strength of the animal, regard also being paid to the length of time the disease has existed; for, when the treatment is commenced too late, the bleeding cannot be carried to the extent that it may be, at an earlier stage of the complaint. As a general rule, bleedings for inflammation of the lungs, should never be continued longer than is necessary to raise the pulse; that is, supposing this to be previously in a depressed state, which, in true pneumonia, it usually is: and in every stage it is quick, and without fulness, even though somewhat hardened. More good is, also, gained by one bleeding within the first twenty-four hours of the disease, than from numerous repetitions of it afterwards. From a moderate-sized horse, five, six, or seven quarts, or even more, may be drawn; and should the symptoms indicate a necessity for it, particularly if the pulse rises on the first bleeding, in five or six hours take three or four quarts more; and as long as the breathing continues laborious, the extremities permanently cold, and the pulse depressed, but rising on the flowing of the blood—so long the bleeding should be repeated to the amount of two or three quarts at a time, at intervals of six or eight hours. This is recommended under a supposition that the treatment commences soon after the attack; but if otherwise, and violent symptoms have existed thirty-six or forty-eight hours, the bleeding must be repeated with more caution, and the pulse most attentively watched; or the opposite extreme may be fallen into, and such debility succeed, as may produce the very event desired to be avoided—namely, the hastening of gangrene or effusion. It is of considerable importance to draw the blood quickly, by means of a large orifice, as directed under General Inflammation, and to suffer the blood drawn, to cool gradually without disturbance, when the buffy surface will have an opportunity of showing itself, and afford conclusions to be drawn whether bleeding should or should not be further persisted in. Immediately after the first bleeding, some active stimulants should be applied to the surface of the chest. Blisters have the effect of taking off the hair, which disfigures the horse for a long time afterwards; and therefore their use is sometimes objected to. They, however, act by stimulating the parts not immediately affected, and prove a counter-irritant; and there is no specific virtue in one matter more than another, beyond its degree of stimulating action to the part to which it is applied. The degree of irritation necessary, must be proportioned to the degree of inflammation it is intended to counteract, by also becoming a counter irritation. (See Blisters). If that be very considerable, the medicinal stimulant must be so likewise; and we know of none whose energy is great in this respect, that will not raise the cuticle, and separate the hair. Consequently, as blisters act powerfully
as stimulants, and particularly as they continue such action for some time, they should never be dispensed with. Whenever, therefore, the symptoms are at all urgent, proceed, at once, to blister the chest, and between the fore legs, and also from the sides behind the elbows; as it should be remembered that active blistering is the quickest mode of subduing the inflammation. The state of the bowels should be next attended to, and gentle relaxation encouraged; but not purging. To obtain this end, back-rake, and throw up a laxative clyster (see List of Medicines); but active purging must, by all means, be avoided. Mr. Coleman formerly recommended, after blistering or roasting, that the horse might be turned out into the open air, however cold, without other medical treatment than nauseating doses of aloes. Latterly he recommended, and with very great propriety, a well-ventilated box, with slight clothing, taking care that the legs are well rubbed and bandaged, either with woollen bandages, or, if not with these, with hay or straw; and should this not have the desired effect of producing warmth in the extremities, a blister to be applied to them, which would be found more efficacious. The muzzle, ears, and the whole of the head, in fact, may be considered as an extremity, and, as such, should likewise be particularly attended to. The ears may be hand-rubbed, and the head clothed in a neck-hood; and the animal littered well up to the belly with clean straw. It must, at the same time, be kept in mind, that the more care taken to promote warmth in the surface and the extremities, by clothing, &c., so the more care should be taken to counteract any tendency these means might have to encourage arterial excitement, which is best effected by a cool and pure temperature of about fifty degrees.

For internal medicine, take of the following immediately after the first bleeding:—

Cape Aloes . . . . 1 drachm.
Digitalis . . . . 1 do.
Nitre . . . . 3 do.
Mix with honey to form a ball.

Give every six hours, or oftener, according to the urgency of the disease. In cases where cough is present and troublesome, add to the former—

 Liquorice powder . . . 2 drachms.

Should this not relieve the cough as much as desired, give—

Linseed Meal . . . 2 oz.
Oatmeal . . . . 2 oz.
Warm Water . . . . 2 parts.
Mix well together, and boil. "Administer this draught every six hours, until relief is obtained. With regard to food, no particular anxiety need be manifested for the first twenty-four hours, during which, the less the animal eats the better, unless green food can be procured for him. This being more cooling and opening, should be given, if possible; but, in its absence, bran mashes may be allowed cold, with only a small quantity of hay. Corn should on no account be given, or the head steamed with hot mashes. As before observed, we must abstain from producing purging, and also carefully endeavour to avoid costiveness. The extremities must also be carefully examined, as to their hotness or coldness, and every endeavour made to keep them as warm as possible. By steadily pursuing this mode of treatment for a day or two, it will then be seen whether the patient is getting better or not. If the fever and inflammation appear to have quite left him, still continue the linseed and oatmeal gruel, in which, once a day, put

Pul. Gentian . . . 1 drachm.
Sulphate of Iron . . . 1 do.

If the disease should occur in mild open weather, the horse would be greatly benefited by being turned to grass, for one or two hours in the warmest part of the day—

PULMONARY CONSUMPTION.

Pulmonary consumption may also be called chronic inflammation of the lungs. It is a disease that commences slowly, but almost always ends fatally. It frequently follows cold, or is a sequel of acute inflammation of the lungs. In these instances, the horse, for some time, seems not to be affected with any disease, though the lungs are decidedly touched the whole time. He is, however, occasionally observed to be affected, and gradually a short dry cough comes on; the coat becomes also harsh, dry, and altogether unsightly. As the disease advances, we always distinguish a peculiar smell about him, rising both from his skin and his dung. At length the appetite becomes affected, and pus, mixed with mucus, which
in the latter stages is mixed with coagula, is observed to be passed from the nostrils. This escapes by the mouth also, as well as the nose, in the act of coughing. In the still more advanced stages, the discharge increases, and is attended with an exceedingly disagreeable smell. The hair falls off in patches, the body wastes, and the complaint either degenerates into farcy or glanders, or the animal sinks under the disease itself. If a horse is destroyed in the early stages, the tubercles appear like knots, or kernels, dispersed through the substance of the lungs. They are sometimes smaller, or larger, as the case may be; mostly darker, but sometimes lighter, than the surrounding substance. In later stages these are found to degenerate into abscesses, and terminate in universal ulceration. When horses are opened at this point of the disease, they are said to be rotten.

Horses affected with consumption, may do a considerable deal of slow draft work, by occasionally giving them one of the restorative balls (see List of Medicines); but a perfect cure is impossible; palliatives being the only remedies that can be made use of.

CHAPTER XXXI.
DIGESTION; INDIGESTION

DIGESTION.
By digestion is meant that process by which the food, or certain parts of it, are converted into a white fluid (resembling milk), named chyle. To render it fit for undergoing this process, which is performed by the stomach, it is necessary that it should be perfectly masticated, and mixed with saliva. Supposing, then, that the food is of good quality, and in sufficient quantity, a defect in the organs of mastication, a deficiency of saliva, or a want of vital power in the stomach, must render the operation imperfect, and the chyle formed by it unfit for the purpose for which it was designed—namely, the formation of pure blood. Mastication is often rendered painful, and, consequently, is imperfectly performed, by a defect in the grinding teeth; that is, by keen edges, or sharp points being formed in the upper grinders, which wound the cheeks, and sometimes are the cause of ulcers being formed there.

Horses constantly fed on dry food, and never allowed grass, are the most subject to this. The upper and under grinders do not meet each other horizontally, but have an oblique inclination inwards; and the grinders of the upper are more distant from each other than those of the under jaw. By this arrangement, the food, as it is ground, falls inward upon the tongue.

The inside of the upper grinders, when worn down nearly to the gum, as happens frequently in horses of the above description, allows some portions of the corn to fall into the mouth before it is masticated, and this is generally swallowed unbroken. The horse feeling sensible of this, tries to throw the wear upon the outer edge by an inclination and peculiar motion of the jaws, which the French express by the phrase "faire les forces." In doing this he often wounds the cheek with the upper grinder, which, in such cases, is always worn to a very keen edge. The cheek inflames and swells, and becomes still more liable to injury. In this way a permanent thickening of the part takes place, and, not unfrequently, deep ulcers. From this cause a horse swallows a considerable portion of his corn without chewing it; and such corn, being indigestible, is always voided with the dung. For a time, this defect may be remedied, by rasping the outer edges of the upper grinders with a concave file made for the purpose. Whenever corn is found in the dung of the animal, there is reason to suspect the

The arrows shew the direction of the food from the esophagus to the rectum.
existence of this defect; but sometimes a horse will swallow corn unchewed, merely from eagerness in feeding. Filing the teeth does not, however, afford permanent relief; for, if a horse is again fed on corn, the teeth once more soon wear to a sharp edge, and the injury is repeated; and though filing off the sharp points prevents him, for a time, from wounding his cheeks, it does not prevent the corn from falling, unchewed, into his mouth, and from being swallowed in that state. There is not, however, so much difficulty in masticating hay, provided the animal is allowed sufficient time. It does not so readily fall into the mouth until it has undergone considerable chewing, and then it is more easily placed under the grinders again, by means of the tongue. The hay is at length masticated with great difficulty, and, after being kept in the mouth a considerable time, is rolled up like a chewed quid of tobacco, and thrown out into the manger. Such horses are named by dealers, gudders; and unless fed upon bruised oats, or soft food, must be starved. In such cases the muscles of deglutition, or swallowing, are more or less paralysed; so that if the animal is turned out, the grass will return through his nose, instead of being swallowed, and he will be starved to death. Horses having such defects in their grinders, should be fed with bruised oats, grains, bran, or other food that does not require mastication.

When a horse is at grass, there is a sufficient supply of saliva for the purposes of mastication, swallowing, and digestion; but when he is taken into the stable, and fed upon dry food, there must, of necessity, be a deficiency of saliva. The only method of compensating for this deficiency, and of rendering the food as fit as it can be made for mastication, swallowing, and digestion, is to dip the hay in water, and make the corn quite wet. This should never be omitted.

There is one cause of imperfect mastication, however, which should not be permitted to happen in the stable; yet it often does happen: and that is, dentition, or cutting teeth, especially when a horse is changing his grinders, which he does between the third and fifth year—not partially, as has been stated, for all the grinders are changed for permanent teeth. A horse ought to be kept out during a great part of this period; and if he is kept in, when he is observed to chew with great difficulty, he should have soft food. A want of vital power in the stomach, is a disease which, in the horse, exists more frequently than persons are aware of, and arises wholly from improper feeding, assisted however, too often by immoderate work. By improper feeding is meant the quantity and quality of the hay that is commonly given. This injures the stomach, not only by its deficiency in nutritious matter, and the impure chyle generated from it—thereby leading the animal to eat a greater quantity than he otherwise would—but by the distension which the stomach suffers, which does it a serious injury, rendering respiration difficult, and weakening the whole muscular system. When a horse is constantly fed in this way, not only the stomach, but all the large bowels are loaded, and the diaphragm is, to a great extent, prevented from performing its office.

INDIGESTION.

In a healthy state of the stomach of a horse, his appetite is such as to lead him to eat only such food as is fit for the formation of pure blood. This food is grass, for he is certainly by nature a graminivorous animal. His stomach is remarkably small, and requires to be frequently supplied; therefore, in a state of nature, we find him almost constantly feeding. How great, then, must be the change which he suffers when taken into the stable; and what serious evils ought we not to expect, unless this change is gradually brought about, and his diet and exercise carefully attended to! When we consider in what manner he is generally treated, there cannot be any difficulty in believing that the stomach must, of necessity, be brought into a morbid condition. The labour he is employed in is generally excessive; the food which is most natural to him is often deficient in nutrient; for even grain is not suitable, because not natural to him; and we find that horses which have always been kept in a state of nature will refuse grain, and require some time, and the stimulus of hunger, to be brought to eat it. Good hay will always be preferred by them, especially when it has that fragrant smell, and greenish colour, which it
ought always to have. But, considering the use to which horses are applied, grain becomes a necessary diet; and, if properly dispensed, is the best food that can be given them. Hay, when really good, and allowed in moderation, is a very suitable diet, but requires to be assisted with grain, in a quantity proportionate to the work to be done. Some grain should always be given; as, without it, the quantity of hay necessary for the support of the animal would so distend the stomach, as to induce gradually, by a continuance of such feeding, a morbid, or deprived appetite. As it is, the hay generally given, even what is considered good, is so deficient in nutriment, difficult of digestion, and is eaten in such immoderate quantities, that the laborious exertions required in the muscular structure of the stomach to extract what nourishment it does contain, is such, as must of necessity bring on a morbid or deprived appetite; and what is, if possible, of still greater consequence, an exhausted state of sensorial power.

Wheaten straw, when the reed has been carefully separated from it, is much better fodder for horses than what is called muddling, or indifferent hay; but the daily quantity should never exceed four or five pounds. Grain must be more freely given in this case, of course; but such a diet is far better than that commonly given to horses in this country.

In France, wheaten straw is very commonly used as food for horses; and the manner the owners have of distributing their diet, well deserves the imitation of the dealers in this country. The daily allowance is given at three different times—viz., a moderate quantity early in the morning, a smaller quantity at noon, and the largest portion at night. It is a general practice, in this country, to give an immoderate quantity of hay at a time. To give even bad hay, to distribute the daily allowance invidiously, both of water and oats—to give beans unbroken, and to work horses while their stomachs are distended with food, much evil is done, and many fatal diseases brought on. So general are these practices, that we meet with but few horses with stomachs in a perfectly healthy condition. So numerous are the degrees of morbidness of the stomach, between the healthy state and that extreme degree of derangement, when the appetite has become depraved, inordinate, and even voracious, that it is difficult, if not impossible, to bring each of them under a distinct head. It will be sufficient for the purpose we have in view, to notice them, as they relate to the organs of respiration; that is, to treat of those diseases of the lungs and their appendages, arising from a morbid condition of the digestive organs. These diseases are commonly known by the name of chronic cough, roaring, and broken wind. To accomplish this in a manner sufficiently clear and intelligible, it is necessary to give a concise description of the organs of respiration, and those of digestion.

The mouth, the tongue, the throat, and the passages to the stomach and lungs, are covered with cuticle, but of various degrees of thickness; so that the sensibility of the different parts is nicely adapted to the purposes for which they are designed. These purposes are—gathering the food, masticating it, moistening it with saliva, and swallowing it. The first is effected by the front teeth; the second by the grinders; the saliva is separated from the blood by three pair of glands, named parotid, sublingual, and submaxillary.

The latter have always been described as lymphatic glands; but there is no difficulty in demonstrating that they secrete saliva, and their excretory ducts may be seen near the tonsils. The parotid glands pour out their saliva through an opening between the second and third grinder, on each side; and the sublingual by two small tubular papillae under the tongue. It is by the motions of this organ that the saliva, necessary not only to facilitate mastication and swallowing, but likewise to perform a very important purpose in the stomach, necessary to digestion, is produced.

The masticated food is placed, by the motions of the tongue, into the upper part of the gullet, or oesophagus, which is named pharynx. The pharynx is large, and capable of considerable dilatation, but soon contracts into a small but strong muscular tube, named oesophagus. The part where the oesophagus begins, is so contracted as to have the appearance of a stricture; and it is here that the strong cuticular, or, as it is commonly named, insensible coat of the stomach, begins. When the food gets into the pharynx, it is swallowed into the oesophagus, and thence falls into the stomach,
by the muscular contraction of those parts. There is a glandular cavity on each side of the throat, named tonsil, which secretes a mucous fluid, which is retained in the cavity until wanted, by a semi-cartilaginous flap. This has been described as the opening of the eustachian tube; but this opening is situated immediately above it. The mucous fluid is forced out by the action of gaping, when it is wanted. The tonsil is the part affected in stranggles; and the matter formed in this glandular cavity, passes down through the excretory duct of the submaxillary gland, inflames it, and causes it to become an abscess. This abscess is commonly, but erroneously, supposed to be the seat of stranggles. The horse's stomach has nearly one-half of its surface lined with a strong cuticular membrane, which lines the oesophagus, and terminates abruptly, and by a fringe-like edge. It is on this part that bots are usually found. Sometimes, however, they leave this part, and attach themselves to the sensitive part of the stomach—properly so named—where the food is nourished and rendered fit for being converted into blood. In the horse, digestion and chylification are performed in the stomach only, not by any particular juice that is formed there, but by virtue of its sensorial power, which it derives in common with all the vital organs; and, in a more especial manner, from the cerebrum or brain, and from that part of the brain named corpora pyramidalia, through the eight pair of nerves, or par vagum, as they are termed.

It appeared necessary to go thus far into a description of the digestive organ—that is, the organs subservient to digestion—in order to impress upon the reader's mind the importance of the stomach in the animal economy; and to show how liable it must be to become diseased, when frequently distended with unwholesome food, containing little nutriment, and requiring great exertion to be digested—such as the hay often given to horses.

CHAPTER XXXII.

INFLAMMATIONS.—INFLAMMATION OF THE HEART; BOWELS; INTESTINES; LIVER; KIDNEYS; BLADDER; NECK OF THE BLADDER.

INFLAMMATION OF THE HEART. Inflammation of the heart is a disease that rarely affects the horse; but it does occur sometimes in conjunction with inflammation of the lungs. In such cases, a quantity of water becomes effused in the pericardium, and constitutes water at the heart. The symptoms are so very much like those of inflammation of the lungs, that it is frequently mistaken for that disease. However, this is rather an advantage than otherwise; for here the same remedies may be brought into application. Still, there is one symptom by which inflammation of the heart may be discovered to have a distinct existence from all other diseases; that is, by the rebounding noise that organ makes at every pulsation, which may be clearly heard by any person standing in the stable, though unacquainted with the disease. Also, by placing the ear to the chest, it will be found that, at every pulsation of the heart, the fluid in the pericardium makes that undulating noise so peculiar to this disease, that it is almost impossible, with a little attention, to mistake it. On examining the pulse at the usual place, it will be found hard and wiry, and occasionally to have a fluttering motion. This will at once suggest the necessity of immediately drawing blood, not in a definite quantity, but as the pulse becomes affected; for if too much be taken, it will increase the debility which the horse is labouring under. However, bleeding must be resorted to; and that as extensively as possible. After this, the bowels must be examined; and if at all costive, he must be back-raked, and clysters of warm
water and salt thrown up until the passage becomes free and open. Also, take of

Mix, and give every six hours. This will not only allay the irritation of the heart, but will moderately open the bowels as required. Place the animal in a loose box, or bay of a barn, and treat, in other respects, as for inflammation of the lungs.

INFLAMMATION OF THE BOWELS.

Next to inflammation of the lungs, inflammation of the bowels is the most frequent and fatal of the local affections to which the horse is subject, and of which there appears two distinct kinds; the one affecting their villous coat, or surface, and producing purging; the other attacking the peritoneal coat, and usually accompanied with obstinate costiveness. It is the latter that forms the subject of our present consideration; the former will be treated of hereafter. From an imperfect acquaintance with the art, it has been common for carriages to mistake inflammation of the bowels for spasmodic colic, and the error has often proved fatal to the affected horse; for the comfortable things, and heating drenches given on such occasions, always increase the inflammation, and frequently produce gangrene. A careful distinction should, therefore, be made between the two, which may readily be done, if sufficient attention is given to the difference of characteristics which they severally display.

The symptoms of inflammation in the bowels are usually first indicated by a shivering fit, to which succeeds heat of skin, restlessness, loss of appetite. The mouth is particularly hot and dry, and the inner membranes of the eyelids, and the linings of the nostrils, rather redder than natural. As the inflammation advances, the pain increases, and forces the animal to lie down and get up again frequently; but, as the pain is less acute, he very seldom rolls on his back, as he does when afflicted with gripes. Sometimes, however, he kicks at his belly, or stamps with his feet; and, in all cases, scarpes his litter or stall with his hoofs, and looks wistfully round towards his sides. The pulse is frequent; sometimes rising to seventy, and hard and wiry; but in gripes or colic the pulse is scarcely ever affected; and even the breathing, in inflammation of the intestines, is not usually so laborious as we at first might expect, in consequence of the painfulness the belly is labouring under. In this, like most other inflammatory cases, the extremities are cold; while the surface of the body is often hot, but scarcely ever exhibits any natural perspiration. The bowels are usually confined; and if any evacuation takes place, it consists of hard, dry matter, rather inclining to a black colour. The urine is made sparingly, and is high-coloured; and a strong sign of the complaint is a very early and excessive debility.

The causes are various; but they are generally dependent on the application of unseasonable cold; such as washing when hot, or plunging the animal into a river. The drinking of cold water has likewise produced it, though more frequently this occasions spasmodic gripes. A long retention of the feces may bring it on; as likewise hernia, or intussusception, which is occasioned by one part of a gut becoming invaginated within another. It may also be produced by metastasis, or the translation of the inflammatory diathesis of another part, or of general fever, or by the communication, by continuity, of the inflammation from other parts, as we have often witnessed. Another, and not unfrequent cause, arises from flatulent colic, either neglected or improperly treated, which many times degenerates into inflammation of the bowels under such circumstances. Calculus concretions have also brought it on.

In treating for this disease, as for most of the other inflamations of important organs, it requires very energetic and early measures to be adopted. Indeed the treatment must here be still more prompt than in most other cases, as an instance of recovery seldom occurs where the treatment has been delayed beyond the second day. In fact, twenty-four hours of this disease frequently destroys the horse. Bleeding is the first thing to be done; and if the subject be young, large, and plethoric, six or seven quarts may be safely taken away. Should the symptoms, after this, continue unabated, the same may be repeated in four hours, to the amount of four or five quarts

more; nor should even a third bleeding, though in a less degree, be omitted in other four hours, if the inflammatory appearances have not become mitigated. The bleeding may be known to have a salutary effect by the pulse becoming softer and fuller, particularly if it shows a disposition to rise as the blood flows. Here also it is proper that the blood be abstracted quickly, and from a large orifice.

As soon as the first bleeding is over, the animal should be back-raked, in order to remove any hardened dung that may obstruct the passage, and which, if suffered to remain, will infallibly aggravate the complaint, and, indeed, in many instances, is the cause of it. The distressing strangury that sometimes accompanies inflammation of the bowels, is also, frequently, as much produced by the pressure of hardened excrement, as by anything else.

It is not the dropping away of a few balls of hardened dung, or the passage of some thin glairy matter, which shows that no obstruction exists; on the contrary, when these are present, a most obstinate costiveness may yet remain farther up in the passage; and a flow of thin fieces may escape by a groove, formed by the side of an obstructing portion of dung. Unless, therefore, there be an evident free passage to all the facial matter, and unless the excrement be wholly softened, it is always proper to rake; for it must not be lost sight of, that whether as a consequence, or a cause, constipation aggravates the disease, and is always present.

A complete recovery seldom, if ever, takes place, until these facial matters are removed. It is always of consequence to bear in mind, that as the state of the bowels, is such as not to render it prudent to allow of strong purgatives being given by the mouth, so the greater activity is required to empty them mechanically, and by the assistance of elyssters, which should be thrown up very frequently. The next thing to be done is to raise a brisk external inflammation over the belly, to lessen thereby the internal affection; and, in this case, even cantharides are hardly quick enough in their action. A more speedy determination to the skin may be made, by first fomenting the belly with hot water for a quarter of an hour, and then by applying a large mustard poultice, farther liquified with oil of turpentine, or with the liquid blister (see List of Medicines), which may be spread on coarse linen, or a horse-cloth. What, however, is still more preferable, is the fleshy side of a newly stripped sheepskin, covered with it, and then applied close to the belly by means of flannel rollers, to retain it in its situation.

When this has remained on for three or four hours, if an evident abatement of symptoms does not show itself, proceed to blister in the usual way. It next becomes a consideration as to what remedies may be given by the mouth, which must greatly depend on the degree of costiveness with which the animal is distressed. In a case where the obstruction does not appear obstinate, we should recommend that castor and linseed oils be given combined—six or eight ounces of each, shaken together, with a little gruel. When the bowels are more closely constricted, take of—

- Solution of Aloes . . . . . . 2 oz.
- Solution of Rhubarb . . . . . . 2 do.
- Good Gruel . . . . . . . . . . . 1 quart.

Repeat this every three or four hours, till full evacuation is obtained. Before the costliness is overcome, care must be taken not to increase the distension of the bowels with much liquid given by the mouth; but when a passage is obtained, take about three quarts of good oatmeal gruel, and the same quantity of linseed-meal tea. Mix these well together, and keep them constantly warm, and occasionally horn a little down; when consumed, repeat the quantity.

This must be the only food given to the horse until a decided amendment is apparent, when he may, by slow degrees, be brought into the use of his ordinary food; but this, at first, must be dealt out to him with a very sparing hand, lest the disease return, in which case it almost always proves fatal. In case the animal is very restless, a loose box would be the most preferable place for him; or, if situated in the country, where no such thing can be obtained, the bay of a barn, or even the floor, well littered down with straw, would be preferable to a stable or stall.

INFLAMMATION OF THE INTESTINES FROM SUDDEN PURGATION.

As the former affection consists of a phleg-
monous inflammatory attack on the peritoneal covering of the intestines, this is usually an affection of their villous surface, the consequence of the administration of improper purging medicines, either as to quantity or quality, by which such a state of irritation is produced as ends in inflammation. It is always accompanied with purging; whereas the former has almost always costiveness connected with it. Neither is the pain so acute in the latter; consequently the horse seldom exhibits so much uneasiness by rolling or stamping. The pulse is also quick and small, but seldom hard. If the symptoms of inflammation be very active; that is, if the pain approaches distress, if the extremities feel cold, and the pulse betokens much vascular action, three quarts of blood may be drawn; but, unless these appearances exist in force, it will be more prudent to omit it. Stimulants should, however, be applied to the bowels, as directed in inflammation of them; the clothing, also, should be warm, and means taken to keep up the circulation in the extremities by hand-rubbing and bandaging. The stable should likewise be kept warm, and the following drink given every four hours:—

Prepared Chalk . . . . 1½ oz.
Rice . . . . . . . 2 do.

Boil the rice in three pints of soft water, until it is a complete pulp; then squeeze it through a fine cloth. Add the chalk to the liquor, breaking down the lumps, and give at a proper warmth. As before instructed, give every four hours. Should this not appear to relieve the animal, take of—

Laudanum . . . . . . 1 oz.
Gum-arabic . . . . . 2 do.

First boil the gum-arabic, in rather more than a quart of good oatmeal gruel; then add the laudanum, and give as before directed. During the exhibition of the medicine, continue to apply clysters of rice and water, made as shown above.

INFLAMMATION OF THE LIVER.

The liver of the horse is, of itself, seldom the first affected with inflammation, though, when other great abdominal inflammations take place, it frequently participates in the disease.

The symptoms of this complaint generally commence in appearances not very unlike a slight attack of inflammation of the bowels; but they are unattended with that rising up and lying down, which, so frequently, is an accompaniment of the latter disease. Still, the horse will often turn his head to his right side, evincing considerable pain; and if his right side be pressed with the hand, he will make a peculiar grunting noise, indicative of suffering. If he be turned round in his stall, to the right hand, it will be with great difficulty, which will further show the pain he is labouring under. The extremities are generally cold; considerable heaving at the flank takes place; the pulse is quick and hard, and the mouth is hot, attended with a yellowness of the lining of the membrane which covers it.

The nostrils and the conjunctiva of the eye also participate in this yellow tinge. These appearances, taken collectively, are the indications which lead to the discovery of this complaint.

The disease is frequently attended with costiveness; and in consequence of the secreted bile not passing off in its usual way, it becomes absorbed in the system; and hence that yellowness of the skin and of the finer membranes. Occasionally, a disagreeable morbid secretion is set up, and the horse's dung becomes loose, and remarkably black, attended with an exceedingly offensive smell. If the disease should terminate in violent discharges of the above-named black fetid stools, the animal frequently falls a victim in a comparatively short time—not longer than two or three days.

For the cure of inflamed liver, first bleed to the full extent of the powers of the animal; and, if necessary, repeat in five or six hours. Well blister the sides of the belly; and if costiveness should appear, back-rake, and throw up clysters of salt and water every three hours; then take of—

Blue Pill . . . . 2 drachms.
Cape Aloe . . . . 3 do.

Form into a ball with honey; and repeat every six hours until it operates.

In cases where purging has commenced, the bleeding should be more moderate and sparing, unless the inflammation run high; in which case discretion must be the guide in the mode of treatment to be adopted, for a repetition of
INFLAMMATIONS.] MODERN VETERINARY PRACTICE. [INFLAMMATIONS.

bleeding is sometimes here less advisable than in the former instance. Take of—

Linsed Meal ..... 2 ounces.

Oatmeal ..... 2 do.

Catechu Pul. ..... 1 do.

Make into good gruel, with three pints of soft water, and give morning and night. If the horse appear weak, and much debilitated, take the following:—

Cape Aloe's ..... 6 drachms.

Sulphate of Iron ..... 6 do.

Powdered Opium ..... 4 do.

Blue Pill ..... 6 do.

Form into a mass with honey; and divide into six balls. Give one every second day.

INFLAMMATION OF THE KIDNEYS.

The horse is very liable to this affection, which is of such a dangerous nature, that if remedial means are not early resorted to, mortification may take place, and the death of the animal be the result.

The symptoms of this disease are various—the animal, for the most part, being dull; the urine also is made in small quantities, and is the colour of porter, and occasionally bloody. As the inflammation increases, the urine becomes sometimes wholly suppressed. He stands with his hind legs wide apart, as if attempting to stale; exhibits great thirst, and is frequently inclined to drink; but this must be guarded against. Diuretic medicine of every description must be carefully avoided, as tending to determine more blood to those organs than is necessary. The legs are apt to swell greatly, and there is a difficulty in moving him in the stall, from the pain which he evinces in his hind quarters. This disease sometimes arises from severe exercise, if taken with a heavy rider. Cold rainy nights will produce it, where the water lodges considerably on the region of the loins.

For the treatment, the principal sheet-anchor is bleeding plentifully, to the amount of from four to six quarts; and, if the inflammatory symptoms still continue for the space of four or five hours, bleed again. After the first bleeding, proceed to back-rake, and clear the rectum out well; then throw up clysters of warm water, until the bowels appear to have a free passage. A blister over the loins might do good; but here it is better avoided, as the active principle of the blister lying in the Spanish flies, may become absorbed, and, entering into the system, do considerably more harm than good; therefore use the following ointment:—

Tartar Emetic ..... 2 drachms.

Hog's Land ..... 2 ounces.

Work well into an ointment, and apply to the loins, night and morning, until pimples make their appearance; then desist. Tie a cradle round the neck, to prevent him biting the part. Clothe moderately; bandage the legs; and for litter, give plenty of good clean straw. For drink, give gruel frequently, in small quantities; feed with hay of the best quality, and moderately; give half bran and half oats, made moist with cold water. Also administer the following every morning:—

Antimony Pul. ..... 12 ounces.

Brimstone Pul. ..... 4 do.

Cape Aloe's ..... 12 drachms.

Mix with honey, to form a mass;

and divide into twelve balls. Give one every morning, the first thing.

INFLAMMATION OF THE BLADDER.

The bladder may become inflamed throughout its whole body, or the affection may be confined to the neck of it only; and as different symptoms arise, as either the one or the other of these are the immediate seat of disease, so we shall describe them separately.

When a mucous membrane is inflamed, it ceases to secrete mucus. This takes place in the inflammation of the internal coat of the bladder; and when it ceases to secrete the irritable portion of mucus, it is constantly endeavouring to rid itself of it.

This complaint may be distinguished from inflammation of the kidneys, by what has been said with regard to that disease; and from inflammation of the neck of the bladder, from what follows.

As the inflamed bladder cannot long retain its contents, so there is a frequent evacuation of a small quantity of urine; and, on passing the hand up the rectum, the bladder will be found hot and tender, but empty. The horse will also be observed to have a disposition to dung frequently, as well as to stale, from the sym-

301
pathy of the rectum with the bladder. The fever is generally considerable, and the pulse is harder and fuller than natural; but as the disease proceeds, it usually becomes oppressed. Its causes may originate in the translation of fever; perhaps sometimes by cold, alternating with heat; and it has been occasioned in mares, by passing some irritating substance up the urethra, to excite them.

Sometimes inflammation of the bladder terminates fatally, in consequence of mortification; but if mucus be again secreted, there is every hope that all things may terminate well, a complete restoration effected, and the animal, after a time, be as capable of performing his duties as ever.

For the cure, bleed according to the height of the fever; and, if no alteration take place for the better, bleed again, as the pulse may indicate; back-rake, throw up clysters of warm water, holding the tail down firm, to prevent their speedy rejection. However, if such should be the case, have ready plenty of hot water to continue the injections, as in this case they act as fomentations to the bladder, and thereby greatly tend to relieve it. For internal remedies, give the same as in the preceding article.

INFLAMMATION OF THE NECK OF THE BLADDER.

Sometimes the neck of the bladder takes on inflammation alone; and this occurs more frequently to horses than to mares.

It is to be distinguished from inflammation of the kidneys, because, in passing the hand up the rectum, the bladder will be found distended. This will also prevent its being mistaken for inflammation of the body of the bladder. The frequent making of a little water will not, however, distinguish either of the foregoing complaints from this, as, in inflammation of the neck of the bladder, there is sometimes a small quantity of urine evacuated at different times; for, after the bladder is distended, there will be, by the force of the distension, a few drops now and then squeezed out. In this disease, however, frequent staling will not take place until the bladder is fully distended; whereas, in the former disease, it will come on at the very first; and likewise in the latter case, the distended bladder may be felt even by the belly. The treatment of this disease is so very much like the two preceding cases, that a repetition of them is here quite unnecessary.

CHAPTER XXXIII.

MORBID POISONS.—HYDROPHOBIA; BITES OF REPTILES; VEGETABLE POISONS; MINERAL POISONS; STINGS.

HYDROPHOBIA.

This disease seldom attacks the horse; and when it does, it arises from the bite of some other animal; such as a dog, or cat, that may be allowed to remain in the stable.

We never saw more than two cases of madness, and those were frightful enough. The first was in a large bay carriage animal, which occurred at the Royal Veterinary College. The symptoms which made their appearance first were, his refusing all kinds of food and water; he was then taken with a kind of shivering fit, after which he broke out into a profuse sweat, stared vacantly around him, began to be extremely restless in his stall; and was then placed in a loose box. No sooner was he placed there than he began to roll and tumble about, reeling and staggering from one side of the box to the other; biting at the manger and rack with the greatest violence; biting his own sides until they bled, and raising his fore feet as high as he could. Indeed, the sight was terrifying to behold; foaming at the mouth, with eyes glaring and glassy. From the
agonising torment the poor animal was in, he was left for a short time; but on returning to the box, he was lying on the floor, completely exhausted. He was immediately ordered to be destroyed.

The most satisfactory symptoms, in cases of this kind, is the dread of water which the horse usually exhibits. Professor Dupuy gives us an account of this circumstance:—

"A rabid horse was confined in one of the sick-boxes. His food was given to him through an opening over the door, and a bucket was suspended from it, and supplied with water by means of a copper tube. As soon as he heard the water falling into the pail, he fell into violent convulsions, seized the tube, and crushed it into pieces. When the water in the bucket was agitated, the convulsions were renewed. He would occasionally approach the bucket, as if he wished to drink; and then, after agitating the water for an instant, he would fall on his litter, uttering a hoarse cry; but he would rise again almost immediately. These symptoms were dreadfully increased if water were thrown upon his head. He would then endeavour to seize it as it fell, and bite with fury at everything within his reach, his whole frame being dreadfully convulsed."

Mr. Youatt says, that if a horse is bitten under suspicious circumstances, he should be carefully examined, and every wound, and even the slightest scratch, well burned with the lunar caustic (nitrate of silver). The scab should be removed, and the operation repeated on the third day. The hot iron does not answer so well, and other caustics are not so manageable. In the spring of 1827, four horses were bitten near Hyde Park, by a mad dog. To one of them the caustic was twice severely applied—he lived. The red-hot iron was unsparingly used on the others, and they died. The caustic must reach every part of the wound. At the expiration of the fourth week the horse may be considered to be safe.

The other case was that of a cart-horse, the symptoms of which were so very like the preceding, that they need little or no description; the horse having been shot after the attack had been on him about three hours. To prevent such cases, no dogs should be suffered to sleep in stables.

BITES OF REPTILES.

Reptiles frequently inflict fatal wounds; but in this country theadder is the only one that we have known to bite either horses or cattle; and when this occurs, and is attended with swelling, take of—

Oil of Turpentine . . . . 2 oz.
Olive Oil . . . . 4 do.

Mix, and rub a portion of the liniment on the parts affected, morning and night.

VEGETABLE POISONS.

Of this class of poisons we have only the yew-tree that produces any particularly deleterious effects upon horses; and when this is once eaten, the animal wastes away by degrees, until death puts a period to his sufferings. Two horses that had been employed in carrying fodder, were thoughtlessly placed under a large yew-tree, of the leaves of which they eagerly partook. In three hours they began to stagger; both of them dropped; and before the harness could be taken off them, they were dead. On being opened, a large quantity of yew-leaves were found in their stomachs, which were contracted and inflamed. The water-dropwort; the water-parsley; the common hemlock; euphorbium, or spurge; coleocynth; elaterium; brary root; savoin; and common brake, are all classed among the vegetable poisons; but there is little danger of the horse hurting himself by them.

MINERAL POISONS.

The numerous minerals given in veterinary practice, do not produce the same poisonous effects which might be anticipated from their name and properties, and which they appear to have when given to the human subject. Arsenic and corrosive sublimate are both used in veterinary practice; but, in all probability, the former will soon disappear from the medical list.

STINGS OF HORNETS.

These are very annoying, and are frequently the cause of much pain and irritation to the horse. We have heard of a horse being attacked by hornets, and stung until the inflammation occasioned proved fatal. The best
application in such cases is vinegar, which put on the inflamed parts, two or three times a day. The spirit of turpentine is also good, and, if administered with discretion, and a proper regard to quantity, mixed with a certain proportion of oil, may be beneficial.

CHAPTER XXXIV.

DISEASES OF THE FEET.—THE FOOT IN GENERAL; CORNS; INFLAMMATION; CONTRACTION, OR NAVA-L DISEASE; GROGGINESS; PUMICED FOOT; OVER-REACHING; QUITHOR; CANKER; FALSE QUARTER.

THE FOOT IN GENERAL.

Whoever has seen the anatomy of the horse’s foot, must acknowledge it to be one of the finest pieces of mechanism ever fashioned by Nature. It ought to form a part of the study of every man who keeps a horse; and if those lovers of horses, the country gentlemen, were well acquainted with the anatomy of the foot, they would, themselves, have an opportunity of preventing the many errors committed by bungling farriers in the shoeing of their horses, and the veterinary surgeon would receive less blame than sometimes falls to his lot. For example: the veterinarian is supposed to be proprietor of a shoeing forge, with several workmen; and, above all, he is supposed to have a foreman, to see that all shall be right. What is the consequence? A gentleman sends for the surgeon, and informs him that his horse is ill-shod at his establishment, and he scarcely can ride him; he stumbles so. The consequence is, that the surgeon orders him to his forge, and promises he will see and attend to the shoeing himself. He does so, and the shoes are taken off, and in all probability their having been nailed on too firmly is the cause of all the evil. This being attended to, under the master’s eye, immediate relief is given, and the horse is sent away with satisfaction. But how is it that neither the foreman, nor any other of the workmen could discover this, but the master alone. Now, if the master have any medical practice, he cannot be in two places at once. Therefore the shoeing department must be left to the foreman, who, unfortunately, frequently understands as much about the matter as the piece of iron he is working on; but, in case of a repetition, the surgeon gets the blame; and, in all probability, he stands a chance of losing an employer. Many persons would say, “How is this; the man has shod horses for these twenty years, and he ought to know?” An easy answer follows: “Does he know the anatomy of the horse’s foot?” “No; I am not aware that he does.”

But to return to the foot. It will not be necessary to advert to the anatomy of that important organ. Our business is to point out its various diseases, with the best means of cure, which we shall endeavour to do; and as corns are so common, we shall treat of them first.

CORNS.

Corns originate in an injury done to one of the most vascular parts; and itself is equally vascular, and instead of tending to increase the cuticle (i.e., the horn) over it, derives its principal character from being inimical to every future growth of it. These very troublesome affections arise from injury done to the vessels of the sensitive sole, exactly at the surface of union between it and the horny sole, whereby blood becomes extravasated within the angle of the inflexions of the heels; that is, between the outer crust and the bars. They appear, in every instance, the effect of improper pressure, by which the sensitive vascular sole becomes acted on between the horny sole and the heels of the coffin-bone. This disease is equally produced, whether the pressure arise from the horn of the sole, or the horn of the walls; and it is from the pressure of the walls
of the heels bruising the sensitive sole, that corns are so common to contracted feet, and also to weak hoofs. It is also to the increased weakness of the inner wall and heel of the hoof that corns are so much more frequent in the inner than the outer heel; and it is from the superior strength of the hinder heels that they are less liable to them. But though the contraction of the walls of the heels does often occasion the complaint, it is much more frequently the consequence of pressure of the sole, the very form of which shows that it never was intended to be thus acted on; for the crust meets the ground, and the sole recedes from it in every part. The general mode in which injurious pressure is given to the sole, is either by an improper form of the shoe applied, by not removing the horn opposed to the seat of corns, or by neglecting to renew the shoe at proper intervals. To one or other of these errors most corns may be attributed.

Bad shoeing operates in various ways, but in none more commonly than by the thickened unequal heel of the shoe, which is, in general, formed into a sort of clubbed end, that prevents its presenting a level surface towards the foot; on the contrary, a bulbous projection indents itself into the very part, as though purposely placed there to produce this injury. The custom, also, of making the seat of the shoe slant, or level inwards, is, we believe, sometimes productive of corns; but the heel, for nearly an inch before its termination, should be made perfectly flat, and the same thickness as any other part of the shoe.

Neglecting to prepare the foot for the shoe is also a fruitful source of corns; for that part of the horny sole which fills up the acute angle, between the crust and the bars, the pressure on which is so injurious, is, in a state of nature, protected by the prominences of the frog and bars, as well as by the inclined direction of the latter; but as artificial habits alter the shape of the foot, this part becomes exposed. Therefore, in preparing a foot for the shoe, this angular portion should be so pared as to remove it from contact with the iron, without weakening the horny covering of the sensitive sole. For so surely as this part becomes subjected to pressure for any considerable length of time, so surely extravasation will take place, and a corn be formed, all the more rapidly if the heels are weak.

The third common cause is the neglect of removing, or renewing, the shoes at proper intervals. When a shoe has been long worn, the growth of the hoof carries it forward, by which the parts originally opposed to the heels are carried beyond them, and now press on the sole, often becoming indented within the line of the crust, and producing a most injurious pressure. Sometimes, also, either from the original form of the shoes, or by long wear, they become loose and "springy," as smiths call it, at the heels; in which cases gravel is apt to make its way between the shoe and the foot, and, by the pressure of the heels during action, is indented into the substance of the horn. Other gravel is received in the same manner, which presses the first still onward, till at last it meets the sensitive part.

As soon as this takes place, inflammation ensues, and a very different complaint is formed to that of common corns; for in every instance of this kind, suppuration proceeds, and the matter, unable to make its exit below, or sideways, forces its way upwards, and a small tumour appears at the coronet, which breaks, and discharges a purulent matter.

But the common effect of pressure from long-worn shoes, is the extravasation of a little blood; which, on paring away the horn at the angular point of the heel, or heels, appears as a black or red speck, as it may have been longer or more newly thrown out from its vessels; and it may be followed with the paring knife to its source in the sensitive part. If the injury has been considerable, this blood itself may irritate, and, similarly to gravel, produce suppuration. In general cases, however, this extravasation remains unchanged; and, unless attended to, a weakened action of this part of the sole becomes permanent, and blood continues to be thrown out ever after, upon any occasional renewal of the pressure. In such cases, the horn itself, over the part, proves a source of future irritation; therefore, horses with old corns, only go well when fresh shod and their hoofs are newly pared; for as soon as the portion of sole between the bars grows to a level with the surrounding horn again, the sensitive sole receives a fresh bruise, and lameness once more appears.
is by contemplating this possible termination of corn, that the law has wisely considered every horse with this complaint as unsound.

In treating for corns, when they first appear, it is not difficult, by proper means, entirely to remove them; but when they have existed some time, the injured parts become weakened, and the diseased action of throwing out blood, instead of secreting horn, becomes characteristic of them. As soon, therefore, as corns are discovered, the care should be immediately attempted; first, by removing, with a fine drawing-knife, every portion of diseased horn around, and the whole of the extravasation likewise; avoiding, however, the wounding of the sensitive sole underneath. Having done this, take a pledget of tow, and well moisten it with compound tincture of myrrh, over which put tow sufficient to fill up the hollow of the foot; put on a bar-shoe, and secure the tow in the hollow of the foot by two sticks, laid across each other, and fastened underneath the edge of the shoe. This will act on the sensitive sole, by destroying the unsound parts, and by stimulating the remainder to a healthy secretion of the parts to produce new horn. Change the dressing every day, and care must be taken not to let the foot get wet. In this way corns may be permanently cured, when not of too long standing.

When the derangement of this part of the sole, however, has become habitual and permanent, a palliative treatment only can be pursued. In the first place, the pressure of the horn must be guarded against, by a regular and frequent paring-out of that portion between the inflexion of the heel; and if the hoof be very strong, and at all disposed to contract, the quarters also should be attended to, and not allowed to become too high, or too thick. We have also, in very strong feet, found the use of a short shoe sometimes of the greatest service; but, to a weak foot, either a chambered or a bar-shoe is preferable. When the weakness is very considerable, or the corn a very bad one, a bar-shoe will be found the best support, and should be constantly used; remembering, in those aggravated cases, to remove occasionally all the surrounding horn likely to press on the injured part; at the same time, taking care not to let the frog rest continually on the bar of the shoe, or it may be apt to bruise it. Whenever such a horse is shod, it is proper for the corn to be dressed with some active stimulant; such as tar, well rubbed in, and covered well with tow to keep the wet and moisture from it. By doing this regularly when shod, and about once a week also in the intermediate time, we have rendered horses, before useless, able afterwards to work with comfort to themselves, and satisfaction to their owners. In slight cases of corn, the shoe proper to be used is one of rather more substance than common, with the web a little wider than usual, and its width equal throughout; that is, as wide at the heels as at the toe. It should also extend to the termination of the heel, and no farther, and be well laid off the quarter, which is, generally, the inner one. This will allow the quarter to expand; and, in all probability, prevent a repetition of the pressure from the bone above. This shoe will afford ease and protection. Future pressure must be avoided by keeping the seat of corns clear from offending.

ACUTE INFLAMMATION OF THE FEET.

Of all the definite and well-marked diseases incident to the horse, this has been most mistaken among the old farriers, and the least noticed among the modern. In many works on Farriery it is not even mentioned; and, in most, is little more than hinted at.

This is almost unaccountable, as it is a disease that is very common among horses. When this disease has come under the notice of the common farrier, he has considered it to be a disease of the chest, in consequence of the horse resting his fore legs, because of the muscles and cellular membrane having become absorbed and wasted away. Hence has arisen the name of chest-founder; and most of the applications were made to the chest of the animal, instead of his feet. It frequently happens that metastasis takes place, or translation of fever from one part to another, as in inflamed lungs, &c. The feet then frequently become affected, whilst the lungs become relieved. In some cases obstructed perspiration will produce it, from sudden alteration of temperature, and standing a long time in the stable, especially if it be kept immoderately warm. The vessels of the feet not being able
to bear the sudden alteration, distend; and inflammation becomes the consequence. In many cases it occurs prior to an attack of symptomatic fever; both diseases being frequently occasioned by long-continued exertion, particularly on hard roads, with subsequent exposure to cold. Under such circumstances, inflammation of the feet may be confined to one foot, or two; or it may attack the whole four; but it is more common to the fore feet.

When a horse labours under inflammation of the feet, persons in attendance on him cannot discover quickly the seat of disease; consequently, he continues to get worse and worse, until a veterinary surgeon is called in, when it is found that the horse is breathing with difficulty, and, in all probability, is in a profuse sweat. The groom then informs him that the animal has been labouring under a severe shivering fit, frequently lying down, stretching out all-fours, and groaning with intense pain. The practitioner soon discovers the seat of disease from the peculiar manner in which the horse stands. He also discovers a singularity in his shifting and lifting up his legs; standing, by drawing his binder legs under towards his chest, to relieve the fore legs from the weight that is naturally upon them. The practitioner will, however, be commonly saved the trouble of much doubt in his examination, for he will, in general cases, not be called in till the features of the complaint are sufficiently developed, by the utter impossibility to make the horse remain on his legs. On the contrary, when forced up, he will lie down again almost immediately, exhibiting every symptom of distress and uneasiness.

As soon, likewise, as the complaint has risen to any height, the feet will be found intensely hot, and the lateral arteries pulsating very strongly. These symptoms alone will serve to mark the disease. There is sometimes a little tumefaction around the fetlocks; and when one foot is held up for examination, it gives so much pain to the other, that the horse is in danger of falling. The poor brute groans and breaks out into profuse sweats, to be succeeded by cold fits. His eyes are moist and red; and his whole appearance shows that he is labouring under a most painful inflammatory affection.

In this state the complaint exhibits itself the first two, three, or four days, after which its effects are various. In the worst cases, when the symptoms we have stated have evidenced themselves a few days, a slight suppuration of the hoof, at the coronet, may be observed. From this may be pressed a small quantity of reddish ichor, or thin matter.

This inflammation, however, is not sufficiently active to force off the hoofs, which have, in a great measure, gradually become imperfect, and sometimes deformed. This imperfect resolution may be known before its effects on the horn have become apparent, by the very peculiar gait the horse has when taken out, and which once seen, can never be forgotten. His manner is to throw his feet forward in a seemingly burlesque style, and bring them down with an odd action on the heel. In fact, he clearly shows that he has lost the proper sensibility of his feet. In other cases, again, of imperfect resolution, the laminae, losing their elasticity and power, yield to the weight and stress of the coffin-bone, which becomes pushed backwards, and, in its passage, draws with it the anterior crust of the hoof, which thus falls in. The pressure also of the coffin-bone destroys the concavity of the horny sole, which, instead, becomes convex or pumiced, leaving a large space towards the toe, filled with a semi-cartilaginous mass, which is not the unfrequent termination of inflammation of the foot.

When the attack is not commenced with extreme violence, or when an early and judicious treatment has been adopted, the inflammation becomes easily removed, and, in the end, the animal will recover the use of his feet.

In treating inflammation of the feet, there is but one certain path to pursue; and that is, on first discovering it, to bleed largely, to the extent of six quarts, at least; and give cold bran mashes, and prepare the horse as for a dose of physic (see List of Medicines; where you can select a ball of any strength, according to the size or power of the animal). The next object is to attend to the feet themselves.

After removing the shoes, pare the feet out nicely, to as great an extent as they will admit; which will not be very much, in consequence of the hardness of the sole, produced by the inflammation. This done, rasp round the foot and the edges of the wall, so that a shoe may be lightly nailed on when required. This
CONTRACTED FEET; OR, THE NAVICULAR DISEASE.

Contracted feet is a disease that has been long known; and "navicular disease" arises, nine times out of ten, out of the former, or is occasioned by it.

Contracted feet are those which have the horn of the crust lessening the natural size of the foot, and pressing upon the sensitive parts within, and thereby causing pain and lameness. This occurs principally on the inner quarter of the crust, because it is the weakest, or thinnest of the two, and is generally the consequence of bad shoeing. There are other causes, however, which contribute to inflammation of the feet; such as too hot stables, and standing on hot dry straw, with little exercise to put the feet into action.

The navicular disease proceeds in a great measure from contracted feet; for, as before observed, as the horn of the crust presses on the soft and sensitive parts within, so the elastic parts become fixed, and the multiplicity of these parts contained within the hoof get diseased, in consequence of being squeezed up, as it were, in a vice: the coffin-bone, the navicular bone, and not unfrequently the small pastern-bone, all become more or less injured.

The reason why the navicular bone is more subject to disease than either the coffin or the pastern-bones, is in consequence of its attachments, and the work it has to do. Every time the horse raises his foot, this bone ascends also, and descends when he puts his foot to the ground; the flexor-tendon, also, being fixed into the coffin-bone, and the navicular bone immediately above it, the small pastern-bone working immediately above that, the whole of the weight of the animal is thrown upon this bone. We ask, then, how can this bone perform its proper functions, when prevented by contraction of the horny box, or hoof, in which it is contained? Of course, any person of common sense will answer, "it cannot!" Hence arises the complaint called navicular disease. We have mentioned that the small pastern rests on the navicular bone. In consequence of the confinement of these bones, their action is not free; and the lower end of the small pastern-bone chafing against the

<table>

<th>INFLAMMATION.</th>
<th>THE HORSE, AND</th>
</tr>
</thead>
</table>
| being finished, bleed each foot largely at the toe; then lightly nail on the shoes (after sufficient blood has been taken from the feet), and place a pledget of tow on each orifice. Over all place a poultice of cold bran, made wet with water; and frequently have cold water squeezed over it from a sponge. In addition to this, apply to the fetlock-joint, what is now termed a "swab" (to be bought of any of the saddlers); but, in case this cannot be done, take a piece of coarse woollen cloth, of sufficient width to go round the leg, and of sufficient length to hang down over the hoof. This must be constantly kept wet with cold water. Sponge-boots we do not approve, as they are apt to induce "thrush," or at least make the frog so rotten, that in mending one hole another is made. The horse should not be encumbered with much litter, unless behind, for his fore legs to stand on; and what is given should be made wet with water. By this means he will have an opportunity of cooling his fore legs as much as possible; and should he be inclined to lie down, which in the early stages of the disease he may, the litter behind will prevent him from injuring his hips or his hocks.

Should the febrile symptoms not seem so speedily to abate as may be desirable, bleed again from the jugular, to the amount of four quarts. An opportunity will now be obtained of gently moving the horse about, which will enable a judgment to be formed as to whether there is any amendment in his feet. If so, the dressing must be continued as before; bearing in mind, that the orifice made in the foot will occasion some degree of lameness.

If the lameness, however, should still appear to be greater, or not at all relieved, bleed in both plat-eveins, abstracting about two quarts from each vein; but do not even think of blistering the coronet, though we know that some practitioners are favorable to this. Give another dose of physic, which is better, in these cases, than all the blisters in the world. By adopting these cooling remedial measures, an amendment both in the feet and the constitution of the horse will be perceived. This, like all other diseases of the feet, will require care and attention, even after the animal has got apparently sound; and will be productive of good. If, while at grass, he should lose his foot-stopping, let it be immediately replaced.

308
navicular bone, sets up inflammation, and the horse goes lame. It unfortunately happens, however, that the poor animal, especially if he is a harness-horse, is still doomed to suffer until the inflammation runs so high, that the absorbents commence their work by removing the fine membrane with which the navicular bone is covered, and absorbing the gristly covering also. The inflammation still being kept up, the bone becomes affected, and caries, or mortification, may take place; and then the navicular disease has arrived at its height.

The principal causes of these diseases we believe to be bad shoeing; though in going over our subject, we shall, in all probability, mention others of a minor nature.

The old-fashioned method of preparing and rasping the feet, has occasioned more lameness than any one thing; for what with paring the frogs away, and opening the heels, as it is termed, with scarcely touching the sole of the foot, was enough to produce contraction; added to which, there was the accompaniment of a very high-heeled shoe. These means, with a little thought, will immediately explain to the experienced horse-man, why the feet of his animal become contracted.

Owners of horses are sometimes to blame in not having their feet pared frequently enough. If the horse should wear his shoes rather light, they will let him go as long as six weeks without paring, and even longer; not thinking of the injury the foot is, all this time, sustaining by its improper growth. No man should let his horse go, without removing the shoes, longer than a fortnight, and new shoes should be put on every month. An opportunity is then given both of examining and paring out the foot properly, and watching that they do not grow out of form; but the custom of nailing the shoes on so exceedingly tight, particularly where the crust is not strong, must affect the feet, and prevent the ordinary expansion.

Shoes of a bad form are very hurtful, except it be for slow-working cart-horses, which have feet of all shapes.

Thick-heeled shoes are sometimes the cause of contraction; but we have seen thin-heeled shoes produce it, by constantly bearing too much on the frog. Still, a moderate bearing on the frog is highly necessary. But there are so many strangely fashioned feet which pass through the hands of a smith, that it is next to an impossibility, unless he be a clever fellow, for him to know what kind of shoe is the best to be generally adapted to them.

We have read of authors wondering how it was that farm-horses had such fine open feet, when they are the worst shod, and mostly with high calkins; but we think the matter is easily solved, when we reflect that their feet are kept open from pressure below; and, though they may have high calkins, and the frog considerably cut away, it is forgotten that the rough land they have to plough, or harrow, perhaps is in balls, the size of large potatoes, all acting as so many expanders while the horse is going over them. Again, if the weather be wet, and the soil damp, this keeps the feet cool and moist; and, of course, renders them more susceptible of expansion.

Artificial heat has a great tendency to produce contraction, especially in hunting-stables, where horses are kept in the highest condition; also, in racing-stables, where they are kept on good dry litter, half-way up their legs, and every hole and crevice stopped to prevent the least air from coming in. The heat that is thus generated, dries up the hoof, and necessarily disposes it to contract.

Heat also, applied by the shoeing smiths, will produce it, if not discontinued; for heat, as they apply it to the foot, has a different tendency during the actual time they are applying it, from the gradual continued heat of the stable. Moisture, on the other hand, has a directly opposite effect, its application greatly tending to counteract the contractile disposition. It also softens the hoof, and assists the weight of the horse in expanding the foot; but sometimes, from the extreme thickness of the hoof, it will not even yield to moisture. In the natural state, it is well known that the hoofs must be accustomed to considerable moisture, of which they are mostly deprived in artificial life. A horse confined to the stable, frequently does not get his feet moistened once a day; but in a state of nature, half his feet may be said to be exposed to moisture half his time, either from dew, or from being immersed in rivers or ponds. Farmers' horses are much more bene-
THE HORSE, AND [CONTRACTION.

...than many others, most of them being generally turned out, and therefore less subject to this disease; though, certainly, the cutting away of the frogs and bars more than is necessary, is the principal cause of contraction in them. Long standing in the stable will frequently produce it, more especially if one foot happens to be lame, which will frequently become contracted from the want of the necessary and natural weight to preserve it in a state of expansion.

The symptoms of contraction of the foot, and navicular disease, are seen in the hoof becoming lengthened; and the frog, instead of having that fullness seen in the natural frog, appears squeezed between the heels, and is not unfrequently ruptured. The feet of all horses do not in contraction become lengthened; but where the heels are very weak, the inside heel may be observed, on standing immediately behind the animal, to turn-in remarkably sharp. When this is the case, horsemen term it being wired in. Sometimes the contraction is principally perceptible round the coronet; but this arises when the disease is subsequent to inflammation of the feet, and the usual secretion at the coronet goes on, but an unhealthy secretion becomes set up. This, however, is not a common case, as contraction generally begins below.

The hind feet are seldom or ever very liable to contraction; and when that does take place, it is not attended with those serious consequences which result when the disease attacks the fore feet, little attention being required to restore them.

The horses of dealers are very liable to contraction, from being removed from the cooling pasture of the farmer, and then travelling, perhaps, from a hundred to a hundred and fifty miles, to be immediately placed in a hot stable. These animals, if their feet are not kept moist, are sure to go lame in the course of a week's time. Contracted hoofs are almost always produced by the causes already detailed; and the general concavity of the sole, with the thickness of its substance, greatly adds to the pain usually felt in progression. From the pain the horse is in during his standing in the stable, he sometimes puts one leg before the other, the most painful one being generally pointed under the manger. This, by horse-

men, is termed "pointing, or fencing," and is a certain sign of the disease. Such an animal, when going on the road, is always inclined to canter; for, if in a walk, or trot, where one fore leg is in the air at a time, it is ten to one but the weight of his rider brings him down. Whenever, therefore, this is observed, however free from lameness he may appear, such feet are diseased; and frequently, on close inspection in these cases, a shortened step may be detected, and a sudden drop of the knee, or fetlock joint, termed "going feehingly," as though he were passing over hot bricks; for such horses seldom or ever step true, but always trip, or stumble.

Nor can we wonder that lameness should be the consequence of contraction, when we consider how exquisitely sensitive are the internal parts of the foot, and how completely they fill up the cavity, which, being lessened, must subject the other parts to pressure, between the hard substances of the coffin-bone, the walls, and sole. Inflammation frequently goes on to that extent, that a deposit of coagulable lymph takes place between the laminae, and sometimes over the sensitive sole, which, in a great measure, destroys its natural sensibility. This is called, by the old farriers, "numbness" of the foot; but this is not the end of the matter, for the inflammation will extend to the bones and cartilages; and while the former throw out bony matter, the latter will become absorbed, and bone be deposited to supply their place. This necessarily produces great lameness and pain to the poor animal.

In treating for this disease, we must observe that feet are of such variety, that a general prescription would not be of much use; but, as we have said that contraction may arise from external as well as internal causes, in many cases palliatives only can be administered. Fortunately, however, where internal derangement has not taken place, although the pressure may be great, and considerable lameness ensue, still the ill effects are not of a lasting nature; for by enlarging the hoofs, the pressure may be removed, and the pain mitigated or entirely taken away. No means, of course, would be equal to a perfect cure; and consequently it would not be wise to recommend a tedious and expensive process, when a palliative mode ought to be adopted; but in the
latter case, a perfect cure may follow a judicious mode of treatment, and therefore these circumstances should not prevent us from trying it. If the contraction has not been of long duration, by proceeding slowly and carefully, this object may be obtained, and particularly if the cause of the disease is ascertained, and if there is every reason to believe that the internal parts are not materially affected.

There have been invented, by many ingenious and clever veterinarians, a variety of mechanical contrivances to remove contraction of the foot; but few of them have been attended with permanent success, though, in some instances, they have afforded temporary relief; but as soon as they were removed, the foot contracted much faster than before.

All these are now done away with, and a more simple and effectual plan has been adopted. This is by applying moisture, and having more regard to shoeing. In extreme cases the operation of neurotomy must be performed. In cases of contraction, take blood from the plate-veins—say two quarts from each—and administer alternative medicines every other day. (See Medicines.) Apply swabs, or woollen cloth, round the hoofs, as directed in the last article, always kept wet with cold water; then direct the farrier to pare out so much of the sole as will cause it to yield to the pressure of the thumb. He must be careful not to remove the bars, or any part of them. The frog likewise must not be cut away, except such ragged parts as may be injurious. The heels may now be rasped down, until they are as low as the crown of the frog, if they will admit of it; if not, as close as possibly can be done. This being accomplished, place on an old thin shoe, with but one nail in the inside, so that it does not press on the inner quarter. Remove all bedding, excepting a little every other night, as the more he stands, the quicker will be the expansion. Give him cooling diet, such as half bran and oats, made tolerably wet; carrots, or clover, grass, &c., &c. Continue this treatment for a week, and watch the progress of it; and, if he should not be particularly lame, let him be exercised two hours, morning and night.

At the Royal Veterinary College, there is an ingenious contrivance to apply moisture to the feet: the floor is taken up where the fore legs of the animal would come, and the earth is removed. The paving is then replaced, and cemented, so as to be water-tight. The horse is then led into this standing, where he remains a considerable time, up to his knees in water. The object of this is to apply continual moisture, adding pressure at the same time; for the moisture must be accompanied with pressure, or the end will not be answered. It is with a view to this purpose that we would order four hours' exercise per day in this disease. Many persons are fond of scoring the hoof at the quarter, with a fine drawing-knife, so that it may have a hinge-like action; but this is of no service without the application of moisture, for the scorings become so dry, that they make the matter worse than it was.

Supposing every resource to have failed in the successful treatment of this disease, we must, at the last, have recourse to excising a portion of the pastern nerve, which is termed neurotomy. This is the only remedy in extreme cases, which are then termed the navicular disease. How to perform this operation we will describe when we come to the subject of Operations.

GROGGINESS.

Groggy feet, by stablemen and grooms, for a length of time, used to be considered an inflammation of the laminae; but, since the anatomy of the horse's foot has become known, it has been discovered to be an inflammatory action going on in the articulating cartilages and their membranes; also in the ligaments connecting the large and small pastern bones, which have sometimes been corroded, and in such a state of disorganisation, as to tend to a bony deposit, and eventually to anchylosis, or stiff joint. We know of no treatment likely to relieve the parts but firing, and repeated blistering. In this complaint the horse will go up upon his toe, the joint immediately within the hoof being stiff. Many working animals in London are affected with this disease, the poor animals sometimes being so excessively lame, as to excite the commiseration of every one who sees them. Professor Stewart, in his Stable Economy, says, "that it is common among all kinds of fast workers; and
long journeys at a fast pace will make almost any horse groggy. Bad shoeing and want of stable care may help to increase, but never can alone produce gogginess. It is one of the evils of excessive work." In most cases it admits of no remedy.

**PUMICED FOOT.**

Pumiced foot is a morbid secretion of the sensitive lamina, which forces the hoof from those laminated parts which cover the coffin-bone, so that a partial separation takes place between the two, whilst an inflammatory attack goes on slowly and gradually. This may be observed by the front of the hoof giving way, or falling in, and receding from its usual obliquity; the sole also, at the same time, becoming nearly flat. This is the time that the horse begins to falter, and show lameness, especially if going over newly-repaired roads; when, if he should tread on a sharp stone, it will probably be with difficulty that he will save himself from coming down. From this curious disease, he appears to secrete little or no horn for the shoe to lie upon, which makes feet of this kind exceedingly difficult to shoe; and still, what appears strange, the sole becomes thinner and thinner, and at length bulges out, forming a perfect convex. This convexity becomes greater, or less, as the disease is more severe. Large cart-horses are very subject to pumice, especially those used in large towns, where they are continually battering their feet on the stones, producing a slow inflammation, ending in pumiced feet from irritation.

The pressure which the coffin-bone, thus displaced, makes on the fleshy sole, sometimes causes an absorption of its own edges, but always an interruption to the healthy secretion of horn. The sole, therefore, being unable to bear the weight of the animal, as it would be in a healthy state, loses its concavity, and yields to the altered form of the parts above it. The whole of the parts within become deranged in structure, as well as situation, and the receding of the coffin-bone towards the heels, where it rests, produces an altered line of declivity.

Palliatives are the only means by which this sort of feet can be treated with any degree of success. A cure is impossible, as the parts can never be reinstated in their original form. Here, shoeing is the principal remedy; and, with this properly done, we have known many horses with pumiced feet work well for a considerable time. With regard to the shoeing, particular attention must be paid to the thinness of the wall, or crust; also, the sole being so exceedingly thin, in putting on, the greatest care is necessary, that no part of the shoe bears thereon. Most smiths are acquainted with the kind of shoe that is best for pumiced feet, it being rather a peculiar one. The framing of this shoe is with an exceedingly wide web, and made thick enough to be, what is called, chambered out very much, almost covering the sole altogether. This is done in order to prevent stones, &c., from injuring the sole of the foot. This shoe should be carefully nailed on, with more than the usual number of nails; but allowance must be made for the extra number in the size, as "fives," or "sixes," will be sufficiently large. This sort of shoe we have found generally to answer exceedingly well; but where it has not answered, we have placed on a bar-shoe, and shouldered it down at the quarters, so that it did not touch the crust, or heels behind. From the form of this shoe, we have seen great benefit arise. After having it placed on, the sole and crust should be well smeared with the following:

```
Alum pul. . . . . . . . . . . . . 2 oz.
Tar . . . . . . . . . . . . . . . 3 do.
```

This application, occasionally used, will harden the hoof and sole; for moisture, in this disease, must be strictly avoided; and horses so affected should never be turned out to grass.

A similar affection to pumiced feet, known by the name of a "Seedy Toe," is thus described by Mr. Spooner, in his work on the foot of the horse:—"It can scarcely be called a disease, but it is rather a natural defect, which may be considerably increased by labour and bad shoeing. It arises from too great dryness of the horn, which renders it brittle, and causes its fibres to separate. There is a want of that tough elastic material which connects the longitudinal fibres together, and produces that strong bond of union between them and the horny laminae of the sole. There is a hollow space within the foot, which sometimes extends upwards and around, so as
to admit a large probe. Neither the bone nor the laminae, however, are exposed, but are still protected by the internal portion of the crust. The only thing to be done is to anoint the foot occasionally, particularly the affected part, with tar and grease. A blister may also be applied to excite the development of a new growth of horn, that which has become dry and brittle being occasionally cut away.

**THRUSH.**

*Thrush* is well known to be a disease of the frog of the foot, and is defined to be a rupture of the cleft of the frog, from which is discharged a highly offensive kind of factid or ichorous matter. In fact, this complaint consists of a diseased action of the sensitive frog; for, instead of secreting that elastic horny substance, composing the healthy frog, it secretes pus, which escapes between the cleft of the horny frog.

Some consider it as of trilling importance, but we have seen it of the greatest consequence, and would recommend great caution in the treatment of thrush, though almost every groom has a sovereign remedy for it; but he probably looks no further than the seat of the disease, not thinking that another affection of the foot is proceeding rapidly, as thrush will sometimes lay the foundation for contraction, by the excitement of the parts around.

The disease is frequently produced by moisture; more especially if it be of an acrid tendency, as that of dung, urine, &c.; but in this case, the hind feet are generally the parts most affected, from their being more in the dung and urine; and there is great danger of its producing grease and canker, if suffered to go on for a length of time. Contraction is a cause of thrush, by squeezing the heels together, until the rupture of the frog takes place. It is not, however, a general cause, as there are many contracted feet without thrush. The different actions of the secreting organs is here made plain; the inflammatory action going on in sensitive laminae, increases the growth of horn, so that the frog never comes in contact with the ground; this, of course, promotes contraction, and the contraction ruptures the frog; and all for want of what? more frog-pressure; for as the frog is deprived of its natural frog-pressure, so do the heels contract, and so will the frog become decreased; consequently, diminishing the secretion of horny frog. A horse, with an open thrush, or what is termed a running thrush, cannot be considered safe; for a stone getting into the cleft of the frog, will invariably bring him down, from the great pain which the pressure of this foreign substance gives him.

It has been argued by some very clever men, that thrush is purely local; but we have seen many cases where it has been constitutional. For example, many horses which have had thrushes, have had them stopped, the parts all dried up, and clean feet brought to view. But, in a few weeks' time, examine their eyes, and it is ten to one but they will be found either blind, or going blind. We have used all kinds of depletive medicine; also tonics; but all to no purpose. Should there be fear of the horse losing his sight, it is better to put up with thrush, which can easily be again produced, by stopping the fore feet with hot horse-dung for a couple of nights.

Thrushes are generally stopped with little difficulty. Almost every astrigent will stop the flowing of thrush. We have known them stopped with tincture of myrrh and tow; but in such cases we should not class thrush among the constitutional, but among the local diseases. Further, horses seldom or ever, with such thrush, go lame, unless it is allowed to go on, when the inflammation, in consequence, produces contraction. Tar alone is a very good remedy. The following is what we have generally used:

- Calamine, prepared . . . . 1 oz.
- White Vitriol . . . . . . 1 drachm.
- Tar . . . . . . . . . . . 3 oz.

Mix well together; but before using, the frog should be well examined, and all the decayed parts, sinus, or wherever the discharge has made its way, removed, so that the application may be thoroughly applied. This will, also, prevent a further harbour for dirt and moisture. The whole frog must now be smeared well over with the mixture; then a pledget of tow taken, well charged with it, and forced to the bottom of the cleft of the frog, and into every other fissure or opening that may be, omitting none. The back parts of the frog, where it joins the heels, are sometimes cracked.
These, also, should be anointed. To dress the feet neatly, great care should be taken that the tow does not hang out, as it may catch objects, and thereby be drawn out. To prevent this more effectually, take a good-sized piece of tow, and place it over the frog, fastening it with two thin pieces of wood, laid across each other. If the case is a bad one, renew the dressing every day; but should it not be so, every second day; always observing the stoppage of tow, to prevent dirt and moisture from getting in.

When a horse is affected with thrush, he should, in no case, be turned out; for the night-dews, besides other liabilities to come in contact with moisture, will inevitably undo all that has been done towards eradicating the disease. Hunters, that have what is called a summer's run at grass, rarely come up to stable, but some of them have got thrush, evidently from the moisture. The groom, probably, thinks this of little importance at the time; though coming into a warm stable, &c., with such an affection, soon proves that the foundation of contraction is laid.

A great many, on this account, assert that thrush is the cause of contraction. In the above case we would strongly recommend the bar-shoe, shouldered down from the quarters.

SANDCRACK.

SANDCRACK may be termed a division of the horny fibres of the hoof, in a direction from the coronet downwards. It is more common to the fore than the hind feet. When the hind feet are affected, it is chiefly amongst cart-horses, but not from the same cause as the fore feet of other horses. Cart-horses, with their immense high-heeled shoes, are apt, from the least irritability, to rub one foot, or the heel of one foot, against the front of the other, thereby causing a sore at the coronet, which splits the hoof downwards, and becomes what is termed sandcrack.

In the fore feet of horses, the disease frequently attacks the quarters, as well as the front of the hoof, especially if this is hard and dry naturally. It may also be brought on by injuries done to the coronet; such as those which arise from stubs, bruises, &c.

The fissure, or cleft, is not always of the same depth; and is sometimes of such a trilling na-

ture as not even to penetrate the horn, where it causes very little inconvenience. This is the state in which sandcrack should be looked to —that is, in its early stage—when the curative process will be much milder, and the disease brought quicker to a termination. At other times it goes through the horn, but does not divide any of the sensitive parts underneath. However, neglect, and continued work, will commonly bring any ease from the slightest to the most aggravated state. When the crack has completely penetrated the hoof, it becomes a most painful affection, and produces extreme lameness. This pain arises principally from the edges of the horn pressing upon the soft parts, whenever the foot is put to the ground.

In treating for sandcrack, different methods, according to the nature of the disease, must be adopted. In the first place, having examined the foot well, the sole should be partially pared out, and the heels lowered, and a shoe put on, laid off the quarters moderately, if the crack is in front. Your next attention must now be given to the cleft or fissure. Not the least particle of dirt should be suffered to remain in it; but should there appear fungus or proud flesh, the probe should be used to feel whether sinuses have been formed. If so, all horn that may cover them, must be removed with a fine drawing-knife, and laid completely bare, to prevent their going further. Touch the fungus then with lunar caustic, and fill the fissure up with tow, saturated in compound tincture of myrrh, first pouring the sinuses full, if there be any, and covering the whole with another piece of tow. This done, bind the whole on with a piece of well-tarred twine. Let this dressing be carefully applied for two or three days, when, if the fissure is going on well, take a firing-iron, and draw it across it, both at the top and bottom. This will prevent its extending either way. Draw your lines almost to the quick, but not through. After this, dress the foot again, binding well up, as before directed. On a second examination, if the parts do not suppurate, they will be found dry, and looking kindly. If this is the case, take a fine drawing-knife, and pare down the edges of the fissure, taking care not to draw blood; and observe if there appear any oozing at the edges. If so, apply a little of the solu-
tion of nitrate of silver to the edges, with the point of a feather: then proceed to dress the wound with tar, fill the fissure full, and smear the foot all over with it. Have ready a pledget of tow, which place over all, as before. Put on a bar-shoe, and lay it off well at the fissure, so that there may be no bearing. Then take the brush, and apply tar all over the foot again. Repeat this dressing at least twice a week.

During the disease, the horse should have eight or ten alternative balls. (See List of Medicines).

**PUNCTURED FOOT.**

Punctured foot is a very common thing with horses, and is frequently attended with a great deal of pain; and in some cases it is followed by death. As the under part of the foot is so continually exposed to sharp bodies of every kind, whilst travelling, it need be no cause of wonder that the foot does occasionally strike upon something by which it receives a puncture. Sometimes, even the heel of the shoe may be too long; and if accidentally the animal should step on it, and partially pull it off, a nail will probably pierce the foot. The accidental puncture of a nail during shoeing, is also one of the most frequent causes of it. Injuries of this kind are proportioned in their effects to the parts injured. A puncture through the fleshy frog, even to the vascular portion, is not so productive of bad consequences, as probably may be a more superficial opening made through the centre of the sole, which may destroy the animal. Whenever a puncture is made of sufficient depth to penetrate the bony connections, and synovia escapes, the parts should be carefully examined with a probe; and if the suppuration has not commenced, apply compound tincture of myrrh on a small bit of lint. This treatment, in a few days, will heal the wound. Do not forget to place a large pledget of tow over all to keep out the wet and dirt.

If this treatment has been neglected, and suppuration has taken place, a bran poultice, moistened well with goulard water, should immediately be applied to the part affected, morning and night; and be renewed every day, until a healthy secretion takes place, when the wound should be dressed with compound tincture of myrrh. Should anything like spongy flesh make its appearance through, touch it lightly with diluted butter of antimony, and put the dressing over the part. These simple modes of dressing will be found to have a much more beneficial effect than most of those violent caustics, so much in common use.

Sometimes deep posterior punctures may penetrate as far as the tendon itself, and produce great pain and inflammation. In such cases, if the accident be early discovered, introduce a little tow, saturated with tincture of myrrh. If the inflammation be great, bleed from the plate-vein, and give alternative medicine (see Medicine) every second day. Should this not reduce the inflammation so quickly as desired, apply a bran poultice, as before directed.

The most common cases of puncture are those which arise from a wrong direction of a nail, during the operation of shoeing, in which it either presses on, or actually wounds the sensitive lamina. This is frequently known to the workman; but, through laziness, he will not draw it out again, or a great deal of injury might be prevented. Were the nail immediately taken out, and a little tincture of myrrh poured down the hole, the smith might introduce a much smaller nail, and all things would go on well.

If suppuration, however, should arise, the shoe must be taken off, and the horn that may have been covering the confined part must be neatly cut away, to its farthest extent, detaching a portion of the fleshy part from the horny sole. Should it proceed upwards, and break out at the coronet, it sometimes takes a long time to heal; but recourse must be had to every means to prevent such an unhappy circumstance. However, after having pared out the sole as directed, next take the probe, and ascertain if any other sinuses are formed. If not, proceed at once to poultice with linseed meal, into which a large piece of Digestive ointment should be well worked. (See Medicines).

Repeat this every day until the wound begins to look healthy. When such is the case, apply tincture of myrrh (first having placed on the shoe), and a large pledget of tow over all, fastened in with two pieces of stick, crossed, as instructed in other applications for the feet. Five or six days may
elapse before the discovery of the disease. If so, have the shoe taken off, and let the smith tap round the foot with his hammer. If the horse does not flinch, let him try with his pincers, by which he will easily discover the seat of lameness, when he should act as directed above.

OVER-REACHING.

Wounds about the coronet are very common, from one foot being set on the other. Hence it is called over-reaching, and generally occurs from a blow of the hind foot against the fore foot, wounding the edge of the coronet, or that part between the hair and hoof. We have known the hind foot strike as high up as the fetlock, and make a complete sore; but such is to be considered only as a simple wound, or rather as a laceration, or bruise. In no case let the old farriers dress the sore, as they invariably apply caustic remedies, which will make the matter much worse than before. First, wash away every particle of dirt that may be in the sore, or around it, with warm water and sponge; then take a pledget of tow, and saturate it in compound tincture of myrrh, and bind on with a linen bandage. Repeat this morning and night until the wound is healed.

As we have here given a remedy for over-reaching, a preventive cannot be out of place. Over-reaching generally occurs in horses having thick, upright shoulders, which partially deprive them of the action of the fore leg, as they cannot throw it out in the bold manner in which horses whose shoulders are placed more obliquely, do. The consequence of this is, that the hind legs, having more freedom of action, reach the fore legs before they are able to get out of the way, which is the cause of what is called over-reaching.

To prevent this disagreeable affection, the horse should be shod high before, which will assist him in getting his fore legs on; and without calfkins behind, which will render their action slower, and thereby make all four legs work in unison.

QUITTOR.

QUITTOR is one of the most troublesome wounds of the foot the veterinarian has to contend with. It must have existed some time when a peculiarly unhealthy state exhibits itself, the ulcerated surface producing a diseased secretion, which may spread considerably around, and, in consequence, affect other parts. The tracts, called sinuses, are not difficult to ascertain, when we see the foot depending; and we all know that matter is sure to find a deepened orifice, if possible; but, when covered with horn, how is that to be obtained? Simply by the spreading of the matter itself amongst sensitive parts, which, in their turn, become diseased. Now the principal care should be to lessen all this, or, in other words, to remove the irritation then existing. But if the injury should extend to the ligamentous and cartilaginous parts, their living powers being small, a very different complaint is formed, and sometimes a very tedious and troublesome one springs up, from the difficulty of forming granulations in parts with such small living powers.

QUITTOR may arise from pricks in shoeing, punctures, and over-reaching; but with draught-horses, the most common cause is from wounds, or bruises, inflicted by a tread on the coronet. We never saw this disease in the front of the foot. It principally occurs at the quarters, in the neighbourhood of the lateral cartilages; although we have heard some say that the whole margin of the coronet is liable.

The great difficulty of treating quittor, from its being so unpleasant a disease to contend with, brought into use, by the older farriers, some of the most violent means of cure. These they adopted from their ignorance of its nature: the burning out with a red-hot iron was one of their favourite plans; but, happily, this is nearly abolished.

A quittor, when it had entered on the process of ulceration, and had dead portions of matter thrown off by suppuration, the farrier would say a core is come out. The wound should then be treated as a simple wound, or abscess; for farriers are too apt, on these occasions, under the idea of assisting the coring out, to introduce strong stimulants. Reduce the inflammation as much as possible, and thin the surrounding horn; and if the matter appears to penetrate in a direct line, downwards only, make an opening in the hoof below; but, in other cases, merely dress in any mild way, either with a weak solution of
sulphate of zinc, or compounded tincture of myrrh. Put the horse on bran mashes, and give alternatives. (See Medicines).

When the complaint has assumed the appearance of confirmed quitter, and no longer retains the character of a simple bruise, wound, or abscess, it must then be considered as an ulcer, composed of different branches or sinuses, or, as the old farriers term them, pipes. Here the coring-out system has been abundantly used. On some occasions of bad quitter, a portion of ossified cartilage has come away; and this is by no means an uncommon occurrence.

In treating for quitter, the first thing to be done, is to examine well with a probe the extent of the ulcer, with the number and direction of the pipes. Should one of the pipes run inward, and come in contact with a firm, hard body, it is more than probable the bone is bare. Portions of the coffin-bone have been known to slough off; but we never know a horse recover when that has been the case. If the capsular ligament becomes ulcerated, and the joints exposed, such a case is a hopeless one, when the pipes run at the back of the cartilages; but when these take an inward direction, they produce a hopeless case. If the direction of the sinuses, however, is outward and downward, or backward towards the heels, the cure then may not prove difficult. The next object is to stimulate the parts to a healthy action, which may be done by introducing any of the following:—Verdigris, or corrosive sublimate (finely powdered), butter of antimony, arsenic, solutions of potash, and lunar caustic. These are all excellent remedies for the disease. Prudence and humanity dictate that the mildest should be tried first. Therefore try zinc, powdered fine, and fill the orifice full, nearly up to the skin, and gently pressing it to the bottom of the wound; then lay a bit of tow over the sore, and bind on with a bit of broad tape. Keep the horse as quiet as possible; and he must not be allowed to go out to grass or to work. If the milder treatment fails, a liquid stimulant, with which you will be able to reach all the sinuses, must be used. Tincture of cantharides, with turpentine, or a mild solution of caustic alkali, or the lunar caustic, introducing small pledgets of tow with whichever of these may be selected, or which may appear the best for combating the disease. Should these also fail in producing the desired object, more active stimulants must be resorted to. Therefore mix about an ounce of tar with finely powdered corrosive sublimate; then take small pieces of tow, and impregnate well with the mixture; next place one of the pledgets thus impregnated at the end of the probe, and lightly press it to the bottom of the sinuses. Do the same until every one is charged; then fill up to the top of the orifice with the mixtures. Caution must be used when introducing the pledgets, so that no force may be felt in the operation. If the quitter should be what the farriers call foul, mix a drachm of verdigris with the above. It would be well to thin the horn a little round the parts, as it will have a tendency to remove the pain that naturally arises. Let the dressing remain on for two or three days, until sloughing takes place. If the parts look red and clean, it may be expected that, by simple dressings of tincture of myrrh, the wound will heal, from its healthy appearance.

If, unfortunately, this should not be the case, proceed again in the same manner as before, until a healthy appearance is made. During the application of these remedies, alterative medicines, every second day, must not be neglected to be given. (See Medicines).

CANKER

Canker is one of the most obstinate and destructive diseases to which the horse is subject. It consists in the separation of the horn of the insensitive from the sensitive sole, caused by suppuration having taken place between the two, and may be variously produced. It may spring from neglected thrush, in which the sensitive sole participates in the inflammation of the sensitive frog. Neglected grease will sometimes occasion it. In both cases it is frequently engendered amongst cart-horses, particularly where they are crowded together, for there is more grease and thrush in large cart-horse establishments than in any other; and if care is not taken in time, canker soon shows itself. It often arises from pricks; and when such is the case, the flexor-tendon becomes injured—in all probability locked-jaw may supervene. Trends, bruises,
or bad corns may now and then occasion it. It seldom occurs in the fore feet, clearly showing that dung and urine are among the gene-
causes.

Canker is a formation of fungus, or proud flesh, produced by an unhealthy secretion, and has the appearance of a cauliflower. In treating for it, the first thing to be done is to reduce this to a level with the parts that appear healthy. This will be effected with a sharp scalpel; and although considerable bleeding will take place, it need give no alarm. Have a bottle of butter of antimony ready (see Medicines), and, with a feather, touch every part of proud flesh, and between the parts. Next proceed carefully, with a probe, to examine what extent of the sensitive is separated from the horny sole; and exactly to the extent of separation must the sole be nicely pared away, with a very fine and sharp drawing-knife; for the horny sole, once separated, never re-unites, but becomes a foreign body, and, as such, injurious. Every portion of separated horn should be carefully removed; and this must be attended to at every future dressing. Again examine, with the probe, if the disease has proceeded in any other direction. If so, it must be treated as above, by a careful removal of all detached parts; let these be cut away, neatly and evenly, and no rough edges suffered to remain.

By using the above means the fungus may be removed; but so long as any of this fungus continues sprouting or growing, so long the cankered action is going on. Before proceeding further, that must be completely done away with; for while it is there, no secretion of firm horn will take place. If a secretion of thin horn, which will sometimes occur over many portions of the surface, is perceived, it must be carefully removed at each dressing, until the application of caustic stimulants and pressure produce a healthy surface, and a proper quantity of pus only, which will finally end in good horn. After the whole of the sole has been brought to secrete good matter, sprinkle it with the following:

<table>
<thead>
<tr>
<th>Sul. Zine, finely powdered</th>
<th>½ oz.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verdigris</td>
<td>1 do.</td>
</tr>
</tbody>
</table>

Sprinkle either of these all over the sole, so as lightly to cover it; then lay a pledget of the finest and cleanest tow on the whole; fill the cavity with other tow thickly over the bottom of the foot, fastened in with strips of wood, as before directed, crossing each other. This will keep up a firm and equal pressure. After this, take a piece of coarse cloth or sacking, and wrap the whole well up in it. This will keep the foot dry, as nothing tends to increase the growth of proud flesh so much as moisture.

There is a great fault in not dressing cankered feet sufficiently often. They ought, at least once a day, to be dressed; and if the case is bad, they ought to be examined morning and evening. Trouble, in this disease, must not be considered; for if the foot becomes neglected, the parts are much longer in healing, and, when healed, are not nearly so firm as if well attended to. Horses affected with this disease should never be turned out. In order to avoid moisture, the mild caustic mode of treatment, with the pledget of tow nicely fitted into the foot, will be found to equal any dressing, when applied with care. Alterative medicines should be given every second day. (See Medicines).

FALSE QUARTER.

False quarter generally arises from one or the other of the preceding diseases; in both of which, from the injury done to the coronary vascular ligament, at one particular part, it can never afterwards secrete horn in a perfect line; but the interruption which first originated between the old and the new horn, continues to be propagated. Consequently, it is called false quarter; and it, of course, very much weakens the foot. Sanderack is sometimes produced by it. The only remedy is, to continually blister the coronet at the quarter; and to shoe with a bar-shoe, well laid off at the seat of disease. The hoof may be dressed with tar, or the foot-ointment (see Medicines), and kept as free from dirt as possible.
CHAPTER XXXV.

SHOEING.

Shoeing, like all other things connected with the horse, has received considerable improvements within the last half century. Indeed, the great improvement made in this department of art, since the establishment of the Royal Veterinary College, precludes the necessity almost of offering an opinion at all on the subject; and the able works of Professor Coleman, Mr. Bracy Clark, and Mr. Goodwin, set forth all that is necessary on the subject. A few observations here, however, seem to be demanded from us. The anatomy of the foot of the horse is now clearly understood, and without such knowledge no man can shoe one properly; and the benefit derived from this knowledge cannot but rejoice those who recollect the numbers of valuable animals that were formerly crippled and rendered useless by ignorance of shoeing. The post-horses, stagers, and hackney coach-horses, were composed principally of crippled horses, or such as were termed goggy in the feet. These poor animals would stand with their feet forward, or, as it is called, pointing, in the greatest anguish, shifting from foot to foot alternately, to gain a little case, their very countenances expressive of extreme pain; but now, comparatively, few so affected are to be seen. With care, the foot may be preserved to the last. Formerly, a young horse, fresh from the breeder, would, in the space of two years, have his feet gradually become unfit and unsafe for any gentleman's riding, and in his very prime he would be cast off to hard labour, rendered more intolerable by increasing pain.

Though the improved system has now become almost so general, that every person employed in shoeing horses knows how it ought to be done; nevertheless, there should be, in practising it, a degree of care which some men will not observe; but will pursue their own way, and fancy they know better than all the veterinary surgeons in the world; and, in spite of every endeavour to teach them, they will do as they like at last. It may be necessary to apprise the man who forges the shoe, whether the horse is apt to interfere, which is called cutting; or whether he over-reaches with his hind foot, striking against his fore shoe; which is extremely unpleasant. These things may be prevented to a great extent, or, indeed, totally, by making a proper shoe, and placing it accordingly. The interfering is remedied by leaving the inner heel as high as possible, and paring the outer heel in moderation, whilst the inner heel of the shoe is made thicker than the outer. This raising of the inner heel throws the fetlock joints outwards, or wider apart; which, with that part of the toe that is liable to interfere, pared close, and the shoe nowise projecting, will prevent the interference, or what is called cutting.

The hind shoe striking against the fore, is prevented by shortening the heel of the hind shoes, so that the hind foot moves in unison with the fore foot; for this striking arises, principally, with heavy forehanded horses, that cannot get their fore feet so quickly out of the way of the hind; and produces that unpleasant noise which arises from their striking, and which, at times, is almost beyond bearing.

When horses, newly shod or removed, go unsteadily or unsafe, which before went safe and well, it is reasonable to suppose that the shoes have not been put on properly. We have seen horses, on being removed from the farrier's shop, go as if crippled at every step, and, to all appearance, as if it were with the greatest difficulty they could keep themselves from falling down. The shoes may seem to be put on right enough, and the nails may appear to be properly driven in, so as not to touch the sensitive part of the foot; but the evil arises from the shoe not having an equal bearing; that is to say, not equal at the heels and at the toe: but we have no objection to the shoe bearing on the outer heel, but it should not, by any means, bear on the heel and quarters inside; for if this be the case,
corn, contraction of the hoof, thrush, &c., will be produced. Although we do not approve of the shoe being so hot when it is applied, as to sear the foot, yet its application should be made when it is moderately hot, to show where the shoe bears, and where it does not, that the rasp may take down some places till the bearing becomes equal. This is a less evil than putting the shoe on at hazard, where there is not equal bearing on the outer side and toe. The driving of the clenches down too much, may cause pain and uneasiness; but it is not so likely to pinch when the shoe sits solidly, as when it does not. For this reason, in shoeing, advise but two nails to be driven in the inside, and those two next the toe. By this the shoe is neither drawn nor warped; for, you must recollect, the shoe not being elastic, and it being nailed to an elastic body, something must give way; and the elastic body will, sooner than the non-elastic: and, further, this occasions the shoe frequently to break; and, what is most singular, the breakage almost always takes place at the quarters where the most elasticity exists; proving that there is not so much fault in the iron, as in the confinement by the shoe of the elastic part of the hoof.

When extreme lameness, and consequent uneasiness happen immediately after shoeing, the shoes should be instantly taken off; to ascertain how they were fitted on; though it frequently occurs, that drawing out the two back nails of the inner quarter will at once give relief. Not that we are to expect horses with bad feet to go so pleasantly in new shoes as old ones. Those with thin flat feet cannot be supposed to go so well as those with strong feet; consequently a different shoe is required. A shoe to, suit soft thin feet, ought to be well chambered out, as it is called, with a broad web, and only bearing on the edge of the crust: but horses having such feet should have the bar-shoe; and until it is, in some measure, settled to the foot, the horse will go tender and unpleasantly.

The substance and weight should be proportioned to the work or employment of the horse. Never load the foot with more iron than is necessary to preserve it. If the foot is light, let the shoe be light also; and if the horse works principally on the road, his shoes should be somewhat stouter. In thus proportioning the weight of the iron to the strength or weight of the hoof, a large part of the art of properly shoeing horses is involved.

CHAPTER XXXVI.

OPERATIONS AND RESTRAINTS.—BRONCHOTOMY; CEPHALOTOMY; NEUROTOMY; DOCKING; NICKING; CROPPING; BLEEDING; PURGING; FIRING; BLISTERING.

When it is necessary to perform any painful or unpleasant operation on the horse, from his strength and power of resistance, it is necessary, for our own security, as well as for the safety of the animal, to restrain him in such a way as to prevent any danger that might otherwise arise from his struggles. Horses, like men, differ much in temper; and some of them, when undergoing any operation, bear pain very differently to others: but it is always wise to be guarded against the worst; and very few important operations should be attempted without casting. Great care should be taken to be as humane as possible, and prevent as much pain as lies in our power; though, at times, means are obliged to be resorted to.

There are other restraints besides the hobble, such as the twitch. This latter instrument is most frequently used by all classes of horsemen; for there is hardly an operation performed that does not require the twitch, which no stable should be without. Still, if used with violence, it is apt to make an animal more uneasy and restive than otherwise; conse-
To the and pass then one by which many business. accidents he move leg, about piece line necessary site. This completes the twitch.

Most persons, and especially the inexperienced, guard only against the hind feet; but they will find that a blow from a horse's fore foot, if properly directed, will come with terrible force. In all operations, therefore, it is best to blindfold the animal, as by so doing he becomes greatly intimidated; nor will he often strike without being much irritated.

Another kind of instrument, principally used by smiths, is what are termed bar-nacles, which is a kind of clam, with a gauging-ring to regulate its tightness, and is sometimes applied to the horse's ear at the time of shoeing. It is, we believe, at times used for the nose; but not unless the animal is first blindfolded. Sometimes all can be done that may be wanted, by an assistant holding up the opposite leg. With regard to holding up the hind leg, one hand should always have a fast hold of the point of the hock. The horse cannot move then without giving warning; and should he feel inclined to kick, you will be enabled to get from him without danger. It is highly necessary that these precautions should be attended to, for two reasons: the one, to prevent any accidents that the operator may be liable to; and the other, that he may not be suspected, by those around him, of not knowing his business.

There is another restraint, called the side-line; and though very simple in its nature, of great use, and now in very general application. Many veterinarians use only the side-line, considering it to be quite sufficient both for the safety of the man and the horse; but, if the animal makes a sudden plunge, it is ten to one that he comes down altogether. It consists of a hobble-strap, and about six or seven yards of rope, nearly the thickness of a man's thumb, and is termed a neck-collar. To make use of the side-line properly, a roller, made on purpose, should be used. It should have several rings on the pad part, both on the sides and top, to answer convenience. All things being ready, put on this, and then slip the neck-collar on, down to the horse's shoulder, and strap the neck-collar to a ring of the roller. By this means, if the horse should by chance hold down his head, the side-line will not get shifted (which it would do, if fastened round the neck alone). Now buckle the side-line on to the fetlock, on the side on which you are to stand; pass the line or rope through the horse's legs, and through the neck-collar, taking it back, after giving it one turn round the collar, to the fetlock. Do the same there; then bring it back again to the collar, where make fast. After this confinement, anything may be done with the horse on the side on which the line is.

Hobbles are used when a horse is to be cast; and then one hobble-leather is placed on each fetlock, each leather having what is termed a D ring attached to it; one ring and leather being fastened to a long rope, very supple, but strong, and about an inch and a quarter in diameter. In putting on the hobble, observe which side you want to cast on. If it be on the off-side, place the rope-hobble on the near fore fetlock, then buckle the three others on, and, taking the end of the rope, hand it to an assistant to thread the off-fore-foot D ring. Let him pass the rope to the off-hind hobbling ring, when you will receive it, and pass it through the ring of the hind hobble of your side. After this, carry the rope up to the near fore foot again, and put it through the ring there; which ring must be considerably larger than any other, because there is double the quantity of rope in it. All this time the horse should be blindfolded. Having your proper strength ready, desire them to pull steady, and together; then you will place your hand against the horse's ribs, at the same time pushing him, when he goes down easily. There is a plan used at the Royal Veterinary College, of one person having a piece of webbing fastened to the roller, who stands at the opposite side, and gives a smart pull, just as the horse is off his legs, which quickly brings him over. By following the above directions, the horse may be said to be rather let down than cast or thrown.

The moment the horse is thrown, the rope must be fastened with what is termed a half-hitch, in which a small pad of straw is inserted, and by which means the rope is drawn much

321
tighter. The person at the head must keep that secure; for all the efforts to disengage himself are first begun by endeavouring to get his head at liberty, so that he may raise his fore parts. Plenty of straw should be placed underneath his head, so that he may lie as easy as possible. Care also must be taken that the horse breathe freely when down, and that no more time be wasted in the operation than is absolutely necessary, as many animals struggle the whole of the time, and exhaust themselves very much.

BRONCHOTOMY.

Bronchotomy is an operation performed on the bronchia, or wind-pipe, in bad cases of strangles, or when tumours exist in the throat, which threaten the animal with suffocation; or if an apple, potato, or a piece of carrot has slipped into the œsophagus, &c.

The operation of tracheotomy is not of a difficult nature, and consists in making a longitudinal section through two or three of the rings, occupying about an inch square, that may be taken away from the front of the cartilaginous substance. A flexible tube should then be introduced into the opening, and retained there as long as possible.—This operation has been performed in cases of roaring; those who performed it thinking the obstruction much lower down than it is.

ŒSOPHAGOTOMY.

The œsophagus may be readily divided, in cases of strangulation, from the obstruction of too large a ball, an apple, or from the accumulation of dry bran and chaff, which sometimes takes place in greedy horses.

NEUROTOMY.

Neurotomy, or the nerve operation, spoken of some time back, now comes under our notice. We have stated that this operation was performed for diseases of the feet, principally of such as are dependent on a contracted form, or otherwise altered in the form of the hoofs, excepting the puniced hoof. The nerves having been long known as the medium of sensation, many cases of lameness in the feet occur, which render horses useless, principally from the pain and tenderness consequent on the pressure of some parts of the foot, long since altered by disease; but which are not now actively engaged in a disorganising process.

Where there is reason to expect considerable disorganisation of the internal parts of the feet, such as ossification, or total absorption of the articular cartilages, or diseased alteration of the bones within; the horny box, or where inflammation of the laminae may have wholly destroyed their sensibility, or where the mucous capsules have, from disease, ceased to yield any, or but a partial supply of synovia—in all such cases the operation cannot be expected to restore the mobility of anchylosed parts, nor can it restore the lost organisation; but, even in such cases, when morbid processes are not actually going on, but seem stationary, and the animal is rather suffering under the effects of former than of present disease, this operation has, by rendering the animal less susceptible to the pain of pressure, enabled him to move and exert himself with more ease to himself, and benefit to his owner. When violent inflammation is in the foot, however, that must be removed, or tried to be removed, before the operation is attempted to be performed.

Sometimes it has happened, in such cases, by removing sensation and rendering the animal willing to exert himself more than the state of the parts will allow, that great aggravation of the disease has frequently followed. We believe it has never been found to answer in the disease called puniced foot; the operation there being particularly hurtful. Neither should we recommend it in any disease of the foot, until we had tried every other means without accomplishing some good. Should success not attend other applications, we should not then hesitate in immediately performing this operation. In others, according to circumstances, with the exception before insisted on. Neurotomy has been found to render many horses with contracted feet, and other wise foot-lamed, not only useful, but has rendered them nearly as perfect, in their mode of going, as ever. Some have hunted, many have made excellent roadsters, and all have been fitted for carriage work of every description.

The importance of this operation, though great in veterinary practice, is in some measure removed, when attended with misfortune afterwards. This may arise from the inflam-
neurotomy.]

MODERN VETERINARY PRACTICE.

NEUROTOMY.

mation not being properly subdued at the time of performing the operation; so that the disease still went on, with all its consequences. However, we prefer the higher to the lower operation, as we have seen less ill consequences arise from it. Some veterinarians prefer the lower one. For ring-bone, the lower one should never be practised. One reason for giving preference to the upper operation to the lower is, that after the operation, the end of the nerve frequently draws itself up, and forms a bulbous end. This coming in contact with the joint, the horse goes as lame as ever in the course of a few days. What is the consequence? Why, the high operation is obliged to be performed, and the horse is immediately upright. If a similar formation manifests a disposition to attach itself to the higher part of the nerve, in this mode of operating, it becomes protected by the tendon, and nothing further is heard of it; for, where no lameness returns, there is reason to suppose that the disease is overcome.

Whilst practising in Devonshire, a very large proprietor of horses, and a mail-contractor, had the misfortune to lose an animal, by both hoofs coming off, and which was not discovered until after he had arrived in the hotel-yard. He evinced not the least lameness during his journey, and was driven by one of the most humane men who ever sat upon a box. Another instance occurred to the same gentleman, and by the same coach. On taking the horses off, one of the leaders appeared to go stiff before; and thinking it was a slight inflammatory action of the foot, his feet and legs were bathed in hot water. On the morrow, however, he could not move his fore feet in the stall, and, of course, a more minute examination was required. This enabled us to detect the bones grating together at the large and small pasterns. The horse was immediately destroyed, and both large and small pasterns were fractured in an oblique direction:—one of the specimens the owner presented us with.

Description of the Plate of Nerve Operation.—This plate shows the two methods that have been commonly employed in performing the operation of neurotomy. It is of the greatest importance to observe that the nerve should be divided with a very sharp knife. The neurotomy knife is the best to use, and should be always kept in good order. Some operators use curved bistourys and scissors, which are superfluous. When the division is made with scissors, that part of the nerve may become numbed, and then it is that the bulbous lump forms, much to the disadvantage of the horse, as well as to the success of the operation.

Description of the Figure.—A represents the horse's leg taken off a few inches below the knee, and also the foot removed. B the situation for the high operation. C the nerve running behind the artery. D the artery. E a blunt-ended needle, armed with white-brown thread, to take up the nerve with. The reason of its being blunt is, to prevent it from injuring the artery. F the two tenaculum, employed to show the parts. The one on the left hand represents the operator's finger drawing back the skin; the one on the right shows the finger of an assistant, whilst the operator inserts the armed needle under the nerve. G the situation of the low operation.

We remarked that preference was given to the high operation, performed even a little higher than the locality marked in the plate. For, when performed in this part, the nervous communication with the foot is more completely cut off, and the cicatrix is quite out of the way of being struck with the other foot.

In this part, the nerve lies rather deeper, especially on the inside of the leg, than it does nearer the fetlock-joint; but there is no difficulty in finding it, if a little cellular membrane is carefully removed. Three-quarters of an inch of the nerve is quite enough to be cut away, and the incision of the skin need not exceed one inch. After the nerve has been cut out, the wound should be closed by one stitch, and a linen bandage should be applied, moistened with cold water, and allowed to remain on for a day or two, when it may be removed, and the wound dressed with compound tincture of myrrh, and tow dipped therein. Apply the bandage again.

Mode of Performing the Operation.—The first thing to be done is to cast the horse in the most convenient and easy place that can be selected. Allow the leg intended to be operated upon to be taken out of the hobbles, and fasten a piece of webbing round the pastern, to be held firm by an assistant; the
NEUROTOMY.]  

THE HORSE, AND

[DOCKING.]

Docking is an operation performed almost on all horses, excepting the racer and the cart-horse; both of which are allowed to enjoy nature's gifts without any curtailing. Still, we cannot but say, that from the improvement which docking makes in our hackney horses, it is not likely that it will fall into disuse. The excessive docking, however, that some horses undergo, does not add to their beauty; although some argue that a short dock strengthens a horse. For ourselves, we are no advocate for the short dock; neither do we approve of docking colts almost as soon as dropped, as being at all beneficial to the future growth of the animal. Early docked colts will have less hair on them than at a more matured age; and as the irritation occasioned by docking in these young animals, makes them apt to rub their tails against anything they come near, it is the cause of making the hair either very rough, or rubbing it off altogether. The length of the dock must be left to choice; about nine inches is the general length now-a-days. When the length has been determined on, the long hair should be fastened back from that part, while, about an inch or two below, it should be shorn clear away. Apply the docking-machine to this part, first finding a joint, and the dock is removed at one stroke. Various means have been adopted to stop the bleeding; but none is equal to the actual cautery, which, if mildly applied, answers every purpose without further trouble. Simple as this operation may appear, the old farriers were wont to make a dreadful fuss over it; and what with burning the horse's tail half off, and resining it besides, it became a matter of wonder that the animal escaped locked-jaw, which frequently supervenes on docking, and the violence used afterwards.

The bleeding scarcely ever proves fatal, and seldom injurious, therefore there is little necessity for cautering; but if the bleeding should continue, the thing to be done is, to take a handful of flour, and, applying it to the end of the dock, draw all the long hair down over it, and tie as close to the dock as possible. This will soon plug up the ends of the arteries, and stop the bleeding.

leg should be suffered to rest on a bundle of hay, or straw, to raise it up for the convenience of the operator. All things being thus arranged, the hair must be clipped close off the part intended to be operated upon, whether it be for the high or the low operation. Then sponge with water; and when the instrument has been used, have ready the sponge in case of profuse bleeding, which is sometimes the case, and is apt to cause confusion, unless the blood be immediately taken up. The pulsation of the artery will now be readily recognised. Then cut down a little posterior to such pulsation, but still keeping the finger on the artery. When a section has been made of about an inch, completely through the skin, lay the knife down, and open the orifice with the thumb and finger, and have it sponged, when the nerve will be seen running immediately behind the artery, perfectly white. Next introduce the blunt-ended needle, under the nerve, and draw it through as far as convenient. After finely dissecting the cellular membrane from the nerve, it may be divided as high up as the section will admit. This will occasion a violent struggle in the horse; but dissect as far down as may be thought proper, and excise what quantity of nerve you like, and he will make no resistance whatever. The skin should be now drawn neatly together, and a stitch or two placed in it; then dress as before described. On removing the bandage, after the first day or two, dress with compound tincture of myrrh. Small pledgets of tow, dipped in this mixture, and applied every day, will soon make the parts heal.

It may clearly be seen, that the motive for using the nerve operation, is to relieve pain. Stallions, with pumiced feet, suffer greatly from pain; and we may be sure, where such is the case, it unmits them from getting healthy progeny. After the nerve operation many of them have proved healthy and vigorous. Mares also, which, from the same causes, have ceased to feel the periodical cestrum, or inclination for the horse, after the operation have resumed their fecundity. The operation is, therefore, not only beneficial in removing lameness, but also bodily pain arising from other sources; which makes it very necessary to be understood.

324
Many persons are very fond of elevating the tail, with an idea that the horse will carry one that is much superior, if done so. But this is not the case. If lock-jaw should make its appearance, immediately operate anew, without restraining the blood at all, as its loss will be both useful and necessary in such a case. Administer large doses of opium, or, if the month should be so much closed, laudanum in gruel must be given frequently; say, an ounce at a time; of the opium, four draehms.

If it should put on a gangrenous appearance, apply oil of turpentine to the part several times a day. Hot applications between applying the turpentine will also be of great service.

**Nicking.**

The practice of nicking is now almost out of date. There is little doubt it originated from the circumstance of large fine horses carrying their tails "tucked in," as it is termed, but which tended to reduce their value, except when they happened to be under excitement, then they would carry their tails erect enough.

With nicking, as with castration, a favourable time of the year should be selected for it; and we should recommend the spring, when the weather is not too hot or too cold; for, in cold weather, the granulating process may become stopped; and, in very hot weather, lock-jaw may supervene. The modes of securing the horse for the operation are various. The break, or trevis, was a favourite mode of the old practitioners, but it is now entirely done away with. A strong rail, or leaping-bar, across a stall, was another means; but these were used only by grooms and dealers. Most veterinarians are in the habit of casting the horse for this operation, and we ourselves have always done so; for the more secure and safe the horse can be made, the less time is taken up in the operation, though dealers are sometimes very expert at performing this operation standing. The more secure way, however, is preferable.

The horse being properly secured, have the twitch ready to place on the nose. Have also two bundles of straw or hay, and raise the horse's feet, so that he may lie on his back; prop him up in this position with the hay or straw, by placing a bundle on each side of him. We should have mentioned that, previous to casting the animal, the hair of the tail ought to have been plaited, and the end neatly turned back, and bound firm with wax-end. When all this has been done, take the nicking-knife, which is double-edged, and which makes it more convenient, and prevents the trouble of turning. The mode of making the sections must be left to the discretion of the operator. They should, however, always be made in the middle of a tail-bone, not at a joint, which will easily be discovered by the prominences rising at either end of the bone. This should be carefully attended to, otherwise the most serious consequences may arise.

It is the practice with some veterinary surgeons to make a section through the integuments only, beginning at the roots of the hair on one side, and carrying it across the bellies of the muscles; then doing the same on the other side; and, lastly, making these sections meet by a light and careful division of the integuments only, on the median lines of the tail. Such is not only a very cautious, but a proper mode for young practitioners, and is also consistent with good practice; but it is apt to take up more time than older and more experienced veterinarians are willing to give it.

The first section should not be nearer, in the smallest horse, than two inches and a-half; and in full-sized animals, three, or three inches and a-half, as the centre of the tail-bones may indicate. In mares, one section less than that in a horse is admissible. The most expert operator will, however, find it prudent, when the sections are made, to examine them carefully, that they are all equal in depth, and that the depressor-muscles have been completely divided.

Should any difference appear in these respects, and should such unequal division be allowed to remain, the operation will be incomplete, and the horse would, in all probability, carry his tail awry. Added to which, any portion of the muscle being left undivided, would tend to prevent the others from retracting, and might also serve to promote a reunion of them. Being satisfied that the sections are all complete, the bleeding that ensues need not be considered of consequence, nor will it show itself until the tail is relaxed. The ends of the tendons must now be looked to, and,
with a sharp and strong pair of scissors, the projecting ends thereof nipped off; enough will always protrude to be taken hold of with the forceps.

The removal of these ends will not only separate the attachments of the muscles further from each other, which, if reunited, would of course frustrate the operation; but their removal will greatly facilitate the healing of the wounds.

The section being thus completed, the hemorrhage must be restrained, which is done in various ways. Some do this by means of strips of cotton, tow, hemp, &c., which is twisted, and inserted into each nick, and separately tied on the back of the tail. As good practice as any is to take a piece of lint, or a pledge of tow, and introduce it into each section sufficient to fill it up, over which place linen strips, long enough to tie on the back of the tail, which is then tied sufficiently tight to restrain the bleeding. Should the bleeding, however, continue to be more than was anticipated, place another, rather broader, linen bandage over each section. It becomes necessary now carefully to watch these bandages, that they do not create too much heat and inflammation in the tail. Should this be the case, and the bleeding not be stopped, take a sponge which has been dipped in cold water, and squeeze the water on the top of the tail several times a day. This will cool the parts, and also tend to stop the bleeding. When perfectly satisfied on this point, loosen the bandages a little; and if all things look favourable, let the tail remain until the morning, when snip the bandage, and set the member free.

Many persons differ in their mode of after-dressing the sections. Some prefer lint only; others lint with the mild digestive ointment, and a bandage over all, in both instances. There is one advantage in dressing with the digestive ointment (see Medicines); and that is, it is apt to promote the suppurrative process, while the other is not. By promoting suppuration, there is more chance of avoiding lock-jaw; but in the first dressing, nothing promotes the healing process so much as dry lint. Watching the wounds, that they be kept from dirt and fungus, leave them to heal of themselves, without any application but the bandages.

Were a nicked tail left to itself, there is no doubt but the divided muscles would again unite, and the tail be carried nearly as it was before. To keep the divided end apart, therefore, it is necessary that the tail should be suspended until the parts become cicatrised, and such junction prevented. In former days, a cushion, or pad, was formed, and fixed to the horse's rump, by means of buckles and straps, and the tail fastened back to this pad.

The Irish nicked horses may always be readily discovered from their having a peculiar curl-up at the end of the tail. This is caused by their having the last joint of the tail broken.

The modern mode of suspending the tail is by double pulleys, which is not only a simple mode, but a convenient one, as they are capable of being regulated at pleasure. The apparatus consists of two pulleys fixed to a beam or joist in the stable, as wide apart as the stall in which the horse is placed. The wheels of these are made sufficiently large to admit of a kind of roller—similar to one used for window-blinds—and about a foot, or a foot and a-half longer than the stall is wide. Another pulley, corresponding to the two others, runs loose on the roller, with this addition—that instead of having an end to fasten up anywhere, there is a larger wheel, but made only wide enough for the suspension cord to run on. This done, the end of the line must be made fast to the horse's tail, by means of first having introduced a good strong skewer through the plait, and double at the end of the tail. Then take another pulley, one end of which is to be fastened to a beam or joist, immediately behind the horse, and as far back as possible. The line fastened to the pulley on the roller is passed over the one just nailed up, and to the end of this line a weight is suspended. By this pulley being in a right line with the centre of the stable, the horse is in no danger of having his tail grow aside; but if he has a tendency to rest on one side of the stall more than on the other, take a bundle of furze, and nail against the side of the stall he may be so inclined to bear against, and vice versa. The weight, for the first day or two, should not be more than will keep the tail straight; then, by
additional weight, elevate the tail a little from the horizontal line, advancing every two or three days, until it has attained the height desired; but never go to the perpendicular or erect position. The elevation, however, ought to depend on the height the tail is wished to be carried in future. The carriage of the tail should therefore be examined every two or three days; keeping in mind, that after the pulleys are no longer used it frequently droops a little.

With regard to giving the horse exercise during the time the tail is in pulleys, we should say it is decidedly wrong, and would cause the animal great and excruciating pain on being placed in them again. It would be very like tearing open an old wound. But there is a means of keeping him in health without exercise, by giving him an ounce of nitre in his water, two or three times a week, and an alterative powder (see Medicines) every day in his feed, which should be half bran and half oats, made moderately wet, so that the powders may easily adhere to it; not sloppy, that the medicine can run off.

Some attention will be requisite with regard to the tail, to prevent the hair coming off; but this will happen in some measure, no matter how great may be the caution used. At the end of about seven or eight days the tail should be taken out of the pulleys, and unplaited; then it should be carefully combed out, and a little hog’s lard applied to the roots of the hair; when made fast again. This should be done every five or six days; and it is the only and best means to keep the hair on, though some cannot be prevented from falling off.

The only things now to be mentioned, are the casualties attending the operation of nicking, the principal of which is inflammation. This may run so high, as to produce mortification, lock-jaw, &c.; but as we have before treated of these specifically, there is no necessity for here repeating what has already been said, which will be found under their respective headings.

CROPPING.

Custom has nearly abolished the practice of cropping. Circumstances, however, may occur to render it necessary; such as one ear becoming blemished; therefore, at the makers of surgical instruments, we can always obtain a sort of curved clamps, called cropping irons. Into these one of the ears is introduced, and the upper part is cut off at one stroke, with a knife of sufficient length. The portion cut off will serve as a guide for forming the other. In this operation a young practitioner is apt to be alarmed at the retraction of the skin from the cartilages; but the exposed edges disappear in a few days. Horses often continue for a long time very shy about the head after cropping; consequently, both bridle and halter should be used without a forepart or fronting, till the ears are quite well. The bridle should also be made to unbuckle on one side from the bit, so that the head-stall may be dropped on, without the hand being raised to pass over the ears. This will naturally operate in dissipating the customary shyness which otherwise so long remains, and which is never wholly lost, if force and cruelty be afterwards used. Gentle means will be always found to be best.

BLEEDING.

Bleeding is practised in several ways. Blood is sometimes taken from the arteries. If the trunk be considerable, it may be punctured, but must afterwards have a ligature passed around it. If it be less considerable, it will be sufficient to divide the trunk of the vessel, which having emptied all its ramifications, recedes by its muscularity within the integument, and the bleeding stops. The temporal artery is occasionally opened on both sides. These arteries may readily be detected at three or four inches below the root of the ear, in a line with the nostrils. The angular artery is sometimes opened for inflammation of the eyes.

Bleeding at the toe also abstracts blood from both veins and arteries. In drawing blood from the foot, it should not be done in the ordinary way of paring down the marginal line, with part of the sole, but the sole only, as close to the marginal line as may be; then a fine drawing-knife, or strong lancet should be taken, and the veins running round the margin of the foot punctured, when, from the great vascularity of the foot, the blood will flow copiously.
With regard to instruments employed to let blood, the common blood-stick and phleme, and a variety of lancets, are in use. The lancet is the most surgical-looking instrument; but, perhaps, the phleme is preferable in country practice, where necks of all thicknesses have to be contended with. We have seen some practitioners make one puncture through the skin first, then another through the coats of the vein; and without some experience the vein is also apt to be altogether missed, in attempting to do it with a lancet. The lancets and phlemes should be always clean, and highly polished; and, after bleeding, their points examined.

Blood is most frequently taken from the jugular vein, though there are other superficial veins, from which blood may be taken with advantage, such as the plate and thigh veins.

The proper place for bleeding at the jugular vein is about two inches below the branching off of that vein, towards the head. To perform the operation, the principal requirement is a steady hand. If the intention is to bleed on the near side, take the phleme in the left hand, and hold it with the finger and thumb. Then, with the middle and third fingers raise the vein by carrying the hand the backward way of the hair. The vein being raised as high as required, strike the phleme with the blood-stick in the centre of the vein. Let your assistant receive the flowing blood in a bucket, whilst you replace your tackle, and prepare, with a pin and tow, to bind up the orifice. This being done, let a wet sponge be applied, and remove the blood.

In abstracting blood, it should be an inviable rule never to let it fall on the ground. A bucket is generally the usual utensil for receiving it. By chance a graduated can is sometimes met with, in well-regulated stables; and exceedingly useful it is; as then you have a certain measure, by which you can regulate the quantity of blood wished to be taken away. You will frequently find you take much more on the graduated principle, than if you trusted to chance. As, for example, in a large horse, with a strong attack of inflammation upon him, on the first bleeding the recovery mainly depends. You are here working in the dark; for it will be next to an impossibility to ascertain what quantity of blood is taken, without some measure for a guide.

In all inflammatory affections, it is important to draw the blood from a large orifice, and as quickly as possible, though the general system may be weakened from hastily drawing blood. The disease, however, gives way to such treatment much quicker than if blood were drawn from a small orifice.

There are two kinds of blood-letting, termed local and general.

Local blood-letting is abstracting blood as near to the part affected as possible; and a few ounces thus abstracted frequently does more good than if a quart were taken from the system generally.

General bleeding is that wherein the system at large partakes of the operation, depleted by the stores more immediately derived from the heart.

Blood-letting, in veterinary practice, is very important. The amazing quickness with which some diseases run their course, and which appear to be only arrested by blood-letting, is, in many instances, to be considered as our only sheet-anchor; and therefore is so much resorted to in most fevers, and those internal inflammatory affections to which the horse is so exceedingly liable. Blood-letting is also important as a criterion of the state of the disease, certain appearances of the abstracted fluid presenting certain indications which act as a guide for future treatment. Indeed, if it were not from a knowledge of the different states of the blood and the pulse, we should be in continual error; therefore, the state of the blood in health, as well as in sickness, should be well attended to.

Purging.

Purging, it is well known, is produced in the horse with the view to renovate him, and to bring him into condition; and though it may be treated lightly by a great many persons, still it is a very important matter, especially when we read of the number of race, and other horses, that annually fall victims on account of the bad management they receive during the time of their physic. Though almost every groom declares he can put a horse through his doses of physic as well as any man, yet, were he asked how the medicine acts, or, if things do not go on quite so well as expected, what is the reason, he is completely puzzled, and does not
know where to look for an answer, or how to explain the meaning of cathartic, or purging medicine.

Cathartics, or purging medicines, act by stimulating the intestines to a more frequent evacuation of their contents. They also increase the matter so expelled; and, under some circumstances, alter the quality of it too. This being the simple operation of purging, it is evident that many erroneous notions are entertained relative to it.

Purging is used to reduce swelled legs; but no purgative will act on the legs immediately; for it cannot, in the first instance, remove fluids from any other parts but the stomach and bowels. Ultimately it may remove the fluids from other parts to make up the deficiency, and thus the legs become lessened.

Notwithstanding there are certain peculiarities of constitution generally, and certain states of the alimentary canal, which particularly render this process very salutary to the horse, and which are essentially necessary to keep him up to that standard of condition which is now the pride of every gentleman and sportsman; still, purging has its limits, and, if carried too far, which is sometimes the case by those ignorant of its effects, it ends in the serious injury, and even the death of the animal.

There are various uses to which purgative medicines become applicable, but they may generally be arranged under such as are given as remedies for existing diseases. Those exhibited as a preventive against a probable one also, are greatly used for promoting a certain state, called condition.

Cathartics are most beneficially used against inflammation, and almost all diseases of increased action, except such as affect the alimentary canal. By increasing the waste of the watery parts of the blood, cathartics tend to deplete the system, and to lessen arterial action. In active inflammation they greatly assist bleeding, and, in other cases, are superior to it, and can be advantageously employed when that cannot be, with propriety, attempted, as in fevers possessing a low or putrid character; for such appear to be often dependent on some morbid change within, or some morbid combinations formed by the biliary fluid, which purging acts particularly upon; so that its advantages here are striking. In plethoric cases, which produce serous deposits in the legs, &c., as in horses just removed from grass, we depend on purgatives for their removal. In pursy, thick-winded animals, physic not only prevents further accumulation, but also stimulates the absorbents to take up some of the existing deposit. In dyspeptic cases, in hide-bound, in lampas, and others, arising from the deranged functions of the stomach, mild purgatives act in the most salutary manner.

In the removal of worms, also, they act most beneficially, by ejecting them, as well as the nidus in which they are lodged.

As preventives, purgatives are extensively employed when horses are taken from grass, or the straw-yard, and at once removed into a heated temperature, covered with clothing, and fed with a full diet. Were it not for bleeding and purging, more particularly the latter, we should find all the consequences of plethora show themselves soon after; as hide-bound, surfeits, swelled legs, cracked heels, ophthalmia, and, not unfrequently, inflamed lungs also. Here, and in all similar cases, purgatives carry off the superabundant blood formed.

It is another fact, which serves to exemplify the absence of analogy between the action of purgatives on the horse and on the human subject. When an emaciated horse is removed from hard work, and harder fare, and at once put to rest and a full diet, so far from his condition being improved, unless he has been prepared for the change by previous purging, his skin becomes fixed, his belly still more and more tucked up, and his hair often actually falls off. The same change, when accompanied by a judicious use of purgatives, operates so much to his advantage, that in a few weeks he becomes almost a new animal.

Physic is also most beneficially given at particular seasons, as at the spring and fall, to obviate the effects of the different states into which horses fall at those times; being then apparently weak and emaciated, yet, at the same time, suffering from increased arterial action, employed in working the periodical change in the constitution. At these times, two or three mild purges will stimulate the defective digestion, remove morbid accumulations from the bowels, occasioned thereby, and,
by a sympathetic effect between the skin and the alimentary canal, they will assist in the change of the new hair for the old.

Purgatives are given to promote condition; and if their tardiness of action altogether shut them out from any other medicinal use, their beneficial influence in producing condition, would, of itself, render the subject important to all those connected with horses. If, likewise, they excited only the condition required in the young, the robust, and the already lusty animal, it would cause little surprise, and the method of action would be clear; but when we know that they equally promote it in emaciated animals, even without apparent disease, it requires an intimate acquaintance with the requisite functions of the animal, to enable us to account for the fact. In such cases we give mild doses only, which prove a valuable stimulant and tonic to the stomach and bowels, thus promoting their digestive powers, and consequent capability of separating more organic molecule from the ingesta. They also stimulate the sluggish biliary and pancreatic secretions, which are so necessary to a healthy digestion, and formation of chyle, from which alone strength and bulk can be augmented. Luxury and refinement have introduced an artificial state of condition beyond that; simply, a healthy functional state.

Such condition is not only necessary to bring the animal up to our present ideas of beauty, but also to enable him to undergo exercise, which, in a state of nature, was not expected from him, as hunting, racing, &c. To promote this state, purgatives are indispensably necessary; and it is from this view that the subject of physicning derives its popularity with the mere horseman: though we hold it in no less consideration under every point of view connected with the well-being of this valuable animal. In promoting condition, purgatives not only act favourably on the digestive organs, but their beneficial influence extends to the other solid and fluid parts of the body also. By their means the watery parts of the blood are removed, the absorbents become stimulated, and take up all the interstitial fluid interposed between the moving masses, as well as that distributed within the cellular membrane; and by this means strength is augmented, and the weight of useless matter diminished. The un-

necessary adeps, or fat of the body, is also removed by the same process, which allows the muscular fibres to be more rectilinearly placed, and, in their action, to be constantly gaining a greater increase of power. It is thus that physic draws up the belly, and hardens the flesh. The lungs also are enabled to act more advantageously by its agency, their capacity being greatly enhanced by the absorption of incumbering matter, either solid or fluid. In this way the wind, as well as the strength, is increased by perfect condition.

Salutary, however, as may be the operation of purgatives on horses, judiciously managed, and properly timed, yet hurtful in the extreme, and often fatal, are the consequences brought about by an ignorant employment of them, and an erroneous mode of managing them when they are employed. In all inflammatory affections of the stomach and bowels, catarrhatics must be highly injurious, except in inflammation of the bowels, when the obstruction cannot be overcome by any other means. They are almost equally hurtful in inflammation of the lungs; and it is probable, from the powers they call forth in the horse to produce purging, occasioned by his structural peculiarities, that in all great visceral inflammations, active purgatives should be admitted with caution. In fancy and glanders, they seldom do other than harm; and in chronic affections, attended with great debility, they are only admissible in some peculiar instances, specified in the treatment of such diseases. Physic is hurtful, however, principally from the frequency and quantity sometimes given. Grooms suppose that every ordinary case requires three doses; the reason for which, many have humorously thus given:—"The first being intended to stir up the humour; the second to set them afloat; and the third to carry them off."

To very young horses, and to delicate feeders, the giving of three doses of physic must be attended with most injurious consequences, and such as they cannot recover from for months; sometimes never. In such cases, one or two very mild doses are all that is required, or ought to be permitted; and it is doubtful, without some "foulness," as it is termed, or rather extreme fulness and plethora, whether, in ordinary cases, two moderate doses
be not all that is necessary to ensure the condition of saddle and carriage horses. It is an unfortunate prejudice, engendered by ignorance, and kept alive by obstinacy, "that to do much good with physic, it must be very strong."

We have many times been told by grooms, that the dose of physic given could not be strong enough, for it had not purged the animal more than fifteen or sixteen times. In many cases, these knowing gentlemen are not satisfied unless a horse have from twenty to thirty evacuations. Super-purgation has destroyed hundreds of animals, and it has irreparably injured thousands. Extra purging debilitates the horse more than the human subject, probably from a lax state of bowels being more common in man, owing to the presence of both cystic and hepatic bile, as well as a dependent situation. It is hardly possible to conceive a more deplorable object than a horse under the action of a too strong purgative; the liquid aliment escaping almost involuntarily from his anus, excoriated with the violence and frequency of the ejections; the belly drawn to the flank, cold sweats bedewing the frame, appetite totally lost, and the strength so decreased as to leave the animal hardly the power of tottering from one stall to another: and yet to this state does the brutality and ignorance of a number of the old farriers doom the horses of their employers. The number and strength of the physiciking doses are not the only evils to which the horse is liable, from improper purgation; the articles used are likewise of an injurious nature. Frequently, with the coarsest aloes, the groom's prescription directs gamboge, which greatly increases its drastic qualities. Neither, indeed, are these persons, or indeed some practitioners, so attentive to previous preparation as they should be.

A powerful dose of physic, given to a horse at hard work, and on full keep, without previous mashing, hurries the hardened faces forwards, until they are formed into an imperviable mass. Inflammation ensues, and on the third day the horse is found dead, and swollen immensely. In hot weather, inflammation supervenies on physic, when at all too active, and dysentery is a very common consequence of summer purging. When good physic has been properly given, it has been often rendered injurious, and even destructive, owing to the carelessness of the persons attending the animal. Cold water, at such times, must not be given; the door must not be left open, or a sudden chill may bring on inflammation of the bowels; also immoderate exercise must be carefully avoided, and only such given as will make the horse comfortably warm, and then he should be brought immediately into the stable.

Of the proper articles to be used in purging, a great discrepancy of opinion prevails; but if the distinction between laxative and purgative be maintained, it would tend to reconcile these differences. There are numerous articles which simply relax the bowels, i.e., slightly increase their peristaltic motion; but very few which produce active purgation. Of the former, bran, calomel, neutral salts, castor, linseed, and olive oils are the most usual; but it must be confessed, that with the exception of bran, all the others occasionally fail. There are some other medicines which act on the bowels, but they are not to be depended on as purgative medicines. The most proper we shall place at the end of this section.

The purgative for horses is, almost in every instance, aloes. Much difference of opinion exists on the preference due to the various kinds of aloes; nor can we ever arrive at a just conclusion on this subject, until we unite a conclave of honest druggists, both wholesale and retail, from whom alone something like a knowledge of the various sorts can only be expected. For all large horses, however, we should decidedly use the Barbadoes aloes for purging; and for small, thin animals, the Cape aloes. But neither large nor small horses should ever be attempted to be purged without first relaxing the bowels with bran mashes.

The quantity of aloes requisite for purgation is also very various, and must depend on the animal's customary food and constitution. This is a matter not to be wondered at, but, nevertheless, is a strong reason against leaving the management of purging to ignorant hands. Some horses are exceedingly difficult to purge, whilst others are easily affected. Old, generally require more than young animals, to purge them; and if at hard meat, it makes much difference in this respect. These facts serve to show the extreme necessity of pre-
Exercise is of the greatest importance in physicng; but not to the severity of either trotting or galloping. Brisk and continued walking is all that ought to be allowed. Half the quantity of any cathartic, with sufficient of walking exercise, will operate nearly as much as a double dose without; so that the degree of purging may be always regulated nearly to our wish. When physic does not work kindly, the exercise should be repeated at short intervals—say two hours—until it does; and then it should be altogether omitted, in case of bringing on fatigue. Chilled water must be given, as it is particularly necessary to recollect that ample dilution of the bowels is of the utmost consequence to ensure the physic working kindly. Entice the horse, therefore, to drink by every means; and on no account forget the necessary precaution of giving him pure water from a perfectly clean pail. When it is either smoked or greasy, it cannot be expected that an animal possessing a delicate palate will drink. During the working of the physic he should be kept warm, both in the stable and by clothing; and he must be exercised (if in winter) in clothes proportioned to the cold.

When a purge is to be given, proceed as follows:—After having fed with bran mashers, for a day or two previous to the one in which you intend giving the ball, give the purge the last thing at night, keeping the animal warm. In the morning, when you come to the stable, offer him warm water, or chilled, but not cold. If you take him out to exercise immediately, the medicine, in all probability, will operate in the course of twenty minutes, or half-an-hour. When such is the case, go home at once, and give a handful of the best sweet hay you can procure. This will recruit his spirits, and he will then be able to eat his mash, which give in about an hour after: Cease now to exercise, until the physic is what is termed set, when feed in the usual way, until another dose is given. Why we recommend giving the medicine at night, is in consequence of its sometimes producing gripes, which generally come on in the night after the morning on which the medicine has been given, and which may cause inflammation of the bowels, and the death of the horse, when no one is present to attend to him. But if the medicine is given

Exercise is of the greatest importance in physicng; but not to the severity of either trotting or galloping. Brisk and continued walking is all that ought to be allowed. Half the quantity of any cathartic, with sufficient of walking exercise, will operate nearly as much as a double dose without; so that the degree of purging may be always regulated nearly to our wish. When physic does not work kindly, the exercise should be repeated at short intervals—say two hours—until it does; and then it should be altogether omitted, in case of bringing on fatigue. Chilled water must be given, as it is particularly necessary to recollect that ample dilution of the bowels is of the utmost consequence to ensure the physic working kindly. Entice the horse, therefore, to drink by every means; and on no account forget the necessary precaution of giving him pure water from a perfectly clean pail. When it is either smoked or greasy, it cannot be expected that an animal possessing a delicate palate will drink. During the working of the physic he should be kept warm, both in the stable and by clothing; and he must be exercised (if in winter) in clothes proportioned to the cold.

When a purge is to be given, proceed as follows:—After having fed with bran mashers, for a day or two previous to the one in which you intend giving the ball, give the purge the last thing at night, keeping the animal warm. In the morning, when you come to the stable, offer him warm water, or chilled, but not cold. If you take him out to exercise immediately, the medicine, in all probability, will operate in the course of twenty minutes, or half-an-hour. When such is the case, go home at once, and give a handful of the best sweet hay you can procure. This will recruit his spirits, and he will then be able to eat his mash, which give in about an hour after: Cease now to exercise, until the physic is what is termed set, when feed in the usual way, until another dose is given. Why we recommend giving the medicine at night, is in consequence of its sometimes producing gripes, which generally come on in the night after the morning on which the medicine has been given, and which may cause inflammation of the bowels, and the death of the horse, when no one is present to attend to him. But if the medicine is given
as directed, at night, then there is the following day to watch him, and take advantage of anything that may occur.

It occasionally happens, that notwithstanding every attention, physic will not work on the second day; in which case, let nothing tempt the practitioner to give another dose immediately; for it sometimes happens that purgatives will not act until the third day. But when a case of non-purgation occurs, always wait until the third day, when, if no symptoms of purging appear, either let the horse rest altogether for two days longer, and then give him rather a stronger dose, or commence by administering to him a quarter of the original dose every six hours, till it purges; giving him mashes, exercise, and warm water, as before directed. Let it also be remembered, that it is erroneous to encourage liquid purging to twenty, thirty, or more dejections. No good attends this practice. We never wish any horse to have more than from twelve to thirteen liquid evacuations. All beyond this weakens the intestines, and injures him.

In the usual course of physic, on the next day after the operation of the purgative, the faces will resume nearly their former consistency and shape, when the physic is said to be set. If it, however, continues to operate with nearly the same violence as on the day before, it must be regarded as super-purgation, and recourse must be immediately had to the treatment already directed for that disease. If otherwise, he may now return to his former habits, giving him corn at first rather sparingly, with moderate exercise; and, in five or six days from the physic setting, if the operation has been only ordinary, a second dose may be given, which is commonly required to be a little stronger than the first. After this, with the same caution, if it be deemed necessary, a third dose may be given, which is usually considered a course of physic; but the number of doses ought never to be under the arbitrary direction of custom, but should be regulated by existing circumstances.

Firing.

Firing is performed for two purposes; one for the forming a permanent bandage, which it does by destroying the elasticity of the skin, and lessening its surface; the other for raising an active inflammation, and thereby exciting absorption. Sometimes it is used to answer one of these purposes only; and sometimes to promote both conjointly.

The Arabs fire the joints of their young colts to strengthen them, by the constant bandage the cicatrix forms to the part. Some English breeders of blood-horses have done the same; but it is rare.

In splinters, sparvins, and ring-bones, firing is used as a strong stimulus to the surrounding absorbents, to remove any extraneous substance recently deposited; hence the osseous matter which forms such swellings, becomes swallowed up by these vessels, and is thus removed. These are instances where firing is used, principally to promote external inflammation to relieve an internal one. But even here, the future pressure, occasioned by the cicatrix, is an assistant, and often a principal, in the removal of the adventitious deposit.

To increase the original inflammation, or to keep it up, it is common in these cases to apply a blister over the firing. In enlargement after violent strains we fire the legs, both to excite the absorbents and to remove the deposit of coagulable lymph; and also, by straightening the skin, to act as a permanent bandage on the part for the future. The various cases in which firing is considered necessary are dispersed through the body of this work; and it would be unnecessary to enumerate them here. We may observe, however, that as it is a painful operation, it should never be resorted to but when absolutely necessary; and the more so, as it leaves a permanent blemish. As blisters act in the same way, except that they leave no permanent blemish; so, when absorption only is required, their repeated application will often supersede the necessity of firing; and as they can be applied as often as wished, as promoters of absorption merely, they are, in many instances, greatly to be preferred. On the subject of blistering immediately after firing, different opinions are entertained.

A morbid sensibility, or rather an affection of feeling, induces some to blame the adoption of such remedial agents as do not square with the popular outcry. A life devoted, as ours has been, to the amelioration of the miseries of some of the noblest of the brute race, prevents
us from inflicting unnecessary or needless pain on them; but when, by momentary addition to their suffering, years of future pain may be prevented, we would not court popularity by joining in decrying all painful operations.

When it is of consequence to keep up the irritation, or even to increase it, which we dare not do by deeper firing, or by lines too near each other, blistering, immediately after, is admissible. Such cases occur in long-continued enlargements, ligamentary, or osseous diseases; but, when firing is applied to four stale extremities, or even to two, which present only the ordinary appearance of disease, it is not only unnecessary, but it is wantonly cruel. It is also dangerous, and has proved destructive.

The mode of firing differs according to circumstances. The general mode adopted at the Royal Veterinary College is in straight lines, up and down the course of the hair, or in perpendicular lines; the reasons for this are well known. If it be applied as a bandage, in no direction can it corrugate the skin in so effective a manner, as by lines drawn inversely to the action, as well as the enlargements of the parts. As the principles of the firing-iron have become perfectly known, it is unnecessary to expatiate upon them here.

As there are several methods of firing, so are there several kinds of irons used for it, of various shapes. The principal are, the searing-iron, which is used for the tail, and which is probably called into request more frequently than any other. Then the budding-iron, for touching cavities, and searing fancy-buds. There is, also, the common firing-iron, the iron to remove lamps, and some others, according to the particular purposes for which they may be required. To practitioners these are all pretty well known, and all should be tolerably thick at the back to retain the heat; and, when used, should only be heated to a dull-red heat.

When performing the operation of firing, care should be taken to have a piece of board near, to rub the edge of the iron on. This will prevent its getting too sharp, and cutting through the skin. The iron, also, by this means becomes cleared of all scales, which would be a very great interruption to the operator if he had no means of speedily removing them.

Firing is not so simple an operation as many persons are inclined to consider it; for, if the true skin is penetrated, a wound is produced, and great inflammation and ulceration may result, and leave a bad blemish. To prevent this, if the iron be made very hot, it must be passed very quickly and lightly over the parts; then, as it gets cool, it can be drawn more at leisure; and, if the parts should not be level, they must be lightly touched over again, in order to make the whole look well. Ridges, or old spavins, require the most severe firing, and are even then not very successfully treated. We have, in that case, fired a second time, which, in many instances, has had the desired effect. In all cases of firing, the hair must be closely clipped off the parts, for the smoke arising from burning is apt to confuse the operator.

We have heard of some operators chalking out the lines first; but we never saw such a practice. After the firing is completed, a mild blister ointment should be lightly applied to the parts; after which the animal should have rest, and not immediately be put to work.

BLISTERING.

Blistering is an operation of great utility, and, when attended with care, it is as safe a one as can be performed. It acts more as a local blood-letting, if care be taken to lance the vesicles as they may arise; for, if these are not quickly removed, the serum may become again absorbed, and the surface restored by a slight effort of inflammation, without having the desired effect. They then become more like what is called sweating-blisters, because the cuticle, or scarf-skin, does not rise; but when, by continued irritation, or by rupturing the vessels, the cutis becomes exposed, suppuration succeeds, and the part becomes thoroughly blistered.

The salutary action of blisters depends, first, on the stimulus they give to the absorbents; and next, on the inflammation they excite, proving a counter-irritant to some other part. They act in the removal of injurious deposits, as enlargements arising from strains of the back-sinews, or ligaments; sometimes they do good when applied to spavins or splents; but, should either of these diseases be of long standing, stronger applications must be had.
MODERN VETERINARY PRACTICE.

recourse to, or the milder blisters used, and repeated every day. Mercurial ointment, well rubbed in on any bony excrescence, for a day or two previous to applying the blister, will greatly tend to promote the absorption of the offending parts.

In inflammatory affections, we find blisters of great importance, acting as counter-irritants; and it appears singular that two inflammations seldom exist in the neighbourhood of each other; therefore, when such an affection has taken place in any part, and it is desired to be removed, we raise an artificial inflammation in its neighbourhood by means of blisters. In inflammatory affections of the lungs and bowels, it is proper to blister the chest, belly, &c., by which means the inflammatory action may be shifted from the vital organs to parts of less importance; for if a horse affected with inflamed lungs be blistered either in the chest or belly, and if the blister does not properly rise, he will probably die of sheer debility. The blister ointment generally ought to be bought at the druggist's, as it is sometimes made of such irritating materials, that the animal is put to the most excruciating pain imaginable, when we well know that the blistering property lies in the cantharides only.

Before applying a blister, the hair should be cut off as closely as possible from the part, and around it. The blister ointment should then be well rubbed in for ten or fifteen minutes, on which thorough application of it, its operation mainly depends. Having done this, smooth the hair downwards, and spread a little more ointment on the surface, with a spatula. If there is occasion to blister the pasterns and fetlocks, apply a little hog's lard to the hollows of the heels. This will often prevent the formation of grease or troublesome sores from the discharge of the blister falling on these parts.

Another caution is, that when a blister is acting, the litter should all be removed from under him, lest the straws tickle and irritate his legs so much, that he may not only attempt to gnaw them, but strike them against the manger, or one against the other. To prevent this, the horse must be tied up to the rack for at least two days, when the principal irritation will have left him. But never blister without putting a cradle round his neck. It will prevent him biting his legs, or attempting to do so. Cradles may generally be had at most of the turners' shops; or, should there be an obligation to make one, take eight or ten pieces of broom or mop-handles, and cut them into lengths of about two feet long, and make holes in both ends, so that they may be threaded with a piece of strong cord, and then fasten them around the horse's neck. The horse then becomes effectually prevented from biting or tearing himself. If blistering once does not answer the purpose anticipated, and you determine to blister again, first wash off, with soap and water, all scurf that may have been left by the first, before applying the second blister. When it is intended to turn a horse out after blistering, care should be taken that all the parts are healed, or flies and dust may get into the sores, and become exceedingly troublesome.

Sweating blisters are generally of a milder nature than others, and in consequence frequently applied.—(See Blistering Liniment)-

CHAPTER XXXVII.

RESTIVENESS.—TAMING SYSTEMS PURSUED BY THE "JUMPER," THE "WHISPERER," MADAME ISABELLE, AND MR. KAREY; VICES.

It has been said of naturally vicious horses, temporarily subdued by some master spirits, that however they may have been cowed and they are never to be depended upon; but will
return to their dangerous practices on any opportunity which their caprice may dictate, or chance may throw in their way. The following statement of facts quite bears out this opinion, and shows the danger of keeping any naturally vicious animal, under the impression that he may become quiet and harmless.

Restiveness may be considered the effect of bad temper, and, perhaps, worse breaking; and like all other habits founded on nature, and fixed by an evil education, it may be considered inveterate. Whether it appear in the form of kicking, rearing, plunging, or bolting, or in whatever way it may threaten danger to the animal or its rider, it rarely admits of a cure. It may be true, that a resolute and determined rider may, to a certain degree, subjugate the animal; or the horse may form his attachments, and, with some particular person, become comparatively, or perfectly manageable; still we believe it to be a rule that admits of very few exceptions, that he neither displays his wisdom, nor consults his safety, who thinks he has so far subdued a restive horse, as to be able, at all times, to repose trust in him.

An excellent veterinary surgeon, and a man of great experience in horses, says, in The Veterinarian—"From whatever cause the vicious habits of horses may originate, whether from some mismanagement, or from natural badness of temper, or from what is called in Yorkshire, a mistetch—whenever these animals acquire one of them, and it becomes in some degree confirmed, they very seldom, if ever, altogether forget it. In reference to driving, it is so true, that it may be taken as a kind of aphorism, that if a horse kicks once in harness, no matter from what cause, he will be liable to kick ever afterwards. A good coachman may drive him, it is true, and may make him go, but he cannot make him forget his vice; and so it is in riding. You may conquer a restive horse; you may make him ride quiet for months, or nearly for years together; but I affirm, that under other circumstances, and at some future opportunity, he will be sure to return to his old tricks again."

This writer gives two singular and conclusive instances of the truth of this doctrine. "When a very young man," he says, "I remember purchasing a horse at a fair in the north of England, that was offered very cheap, on account of his being unmanageable. It was said that nobody could ride him. I found that the animal objected to have anything placed on his back, and that, when made to move forward with nothing more than a saddle on, he instantly threw himself down on his side with great violence, and would then endeavour to roll upon his back."

"There was, at that time, in Yorkshire, a famous colt-breaker, known by the name of 'Jumper,' who was almost as celebrated in that country for taming vicious horses into submission, as the famed 'Whisperer' was in Ireland. I put this animal into 'Jumper's' hands, who took him away, and in about ten days brought him home again, certainly not looking worse in condition, but perfectly subdued, and almost as obedient as a dog; for he would lie down at this man's bidding, and only rise again at his command, and carry double or anything. I took to riding him myself, and may say, that I was never better carried for six or eight months, during which time he never showed the least vice whatever. I then sold him to a Lincolnshire farmer, who said that he would give him a summer's run at grass, and show him a very fine horse at the great Horncastle fair."

"Happening to meet this gentleman the following year, I naturally enough inquired after my old friend. 'Oh,' said he, 'that was a bad business—the horse turned out a sad rebel. The first time we attempted to mount him, after getting him up from grass, he in an instant threw the man down with the greatest violence, pitching him several yards over his head; and, after that, he threw every one that attempted to get on his back. If he could not throw his rider, he would throw himself down. We could do nothing with him, and I was obliged at last to sell him to go in a stage-coach.'"

In the next story, "Jumper's" counterpart, and superior, the Irish "Whisperer," is brought on the stage, and, although he performs wonders, he cannot radically cure a restive horse. "At the Spring Meeting of 1804, Mr. Whalley's 'King Pippin' was brought on the Curragh, at Kildare, to run. He was a horse of the most extraordinarily savage and vicious disposition. His particular propensity was that of
MODERN VETERINARY PRACTICE.

TAMING.

ing at and worrying any person who came within his reach; and if he had an opportunity, he would get his head round, seize his rider by the leg with his teeth, and drag him down from his back. For this reason he was always ridden in what is called a sword; which is nothing more than a strong flat stick, having one end attached to the cheek of the bridle, and the other to the girth of the saddle, a contrivance to prevent a horse of this kind from getting at his rider.

"King Pippin had long been difficult to manage, and dangerous to go near; but on the occasion in question, he could not be got out to run at all. Nobody could put the bridle upon his head. It being Easter Monday, and, consequently a great holiday, there was a large concourse of people assembled at the Curragh, consisting principally of the neighbouring peasantry; and one countryman, more fearless than the rest of the lookers-on, forgetting, or, perhaps, never dreaming that the better part of courage is discretion, volunteered his services to bridle the horse. No sooner had he committed himself to this operation, than King Pippin seized him somewhere about the shoulders, or chest, and shook him as a dog would shake a rat. Fortunately for the poor fellow, his body was very thickly covered with clothes, for, on such occasions, an Irishman of this class is fond of displaying his wardrobe; and if he has three coats in the world, he is sure to put them all on.

"This circumstance, in all probability, saved the individual who had so gallantly volunteered the forlorn hope. His person was so deeply enveloped in extra clothing, that the horse never got fairly hold of his skin; and I understand that he escaped with but little injury, beside the sadly rent and totally ruined state of his wardrobe.

"The 'Whisperer' was sent for, who, having arrived, was shut up with the horse all night, and, in the morning, he exhibited this hitherto ferocious animal, following him about the course like a dog; lying down at his command; suffering his mouth to be opened, and any person's hand to be introduced into it; in short, as quiet as a sheep.

"He came out the same meeting; and won a race, and his docility continued satisfactory for a long time; but, at the end of about three years, his vice returned, and then he is said to have killed a man, for which he was destroyed."

It may be interesting to give some account of this extraordinary tamer of equine vice.

The Rev. Mr. Townsend, in his Statistical Survey of Cork, first introduced the "Whisperer" to the notice of the public generally, although his fame had, long before, been spread over that part of Ireland. He is mentioned also in Croker's Fairy Legends and Traditions of Ireland. The following is an extract from that work:

"He was an awkward, ignorant rustic, of the lowest class, of the name of Sullivan, but better known by the appellation of the 'Whisperer'; his occupation was horse-breaking. The nickname he acquired from the vulgar notion of his being able to communicate to the animal what he wished by means of a whisper, and the singularity of his method, seemed in some degree to justify the attribute. In his own neighbourhood, the notoriety of the fact made it seem less remarkable; but I doubt if any instance of similar subjugating talent is to be found on record. As far as the sphere of his control extended, the boast of veni, vidi, viei, was more justly claimed by Sullivan than by Caesar himself.

"How his art was acquired, and in what it consisted, is likely to be of ever unknown, as he left the world without divulging it. His son, who followed the same trade, possessed but a small portion of the art, having either never learned the true secret, or having been incapable of putting it into practice. The wonder of his skill consisted in the celerity of the operation, which was performed in privacy, without any apparent means of coercion. Every description of horse, or even mule, whether previously broken, or unhandled, whatever their peculiar habits or vices might have been, submitted without show of resistance to the magical influence of his art; and in the short space of half-an-hour became gentle and tractable. This effect, though instantaneously produced, was generally durable. Though more submissive to him than any others, they seemed to have acquired a docility unknown before.

"When sent for to tame a vicious beast, for which he was either paid according to the dis-
tance, or generally two or three guineas, he directed the stable, in which he and the object of the experiment were, to be shut, with orders not to open the door until a signal was given. After a tête-a-tête of about half-an-hour, during which little or no bustle was heard, the signal was made, and, upon opening the door, the horse appeared lying down, and the man by his side, playing with him like a child with a puppy dog. From that time he was found willing to submit to any discipline, however repugnant to his nature before."

"I once," continues Mr. Townsend, "saw his skill tried on a horse which could never before be brought to stand to be shod by a smith. The day after Sullivan's half-hour's lecture, I went, not without some incredulity, to the smith's shop, with many other curious spectators, where we were eye-witnesses of the complete success of his art. This, too, had been a troop horse; and it was supposed, not without reason, that after regimental discipline had failed, no other would be found available. I observed that the animal appeared terrified whenever Sullivan either spoke or looked at him. How that extraordinary ascendency could have been obtained, it is difficult to conjecture.

"In common cases this mysterious preparation was unnecessary. He seemed to possess an instinctive power of inspiring awe, the result, perhaps, of natural intrepidity, in which, I believe, a great part of his art consisted; though the circumstance of the tête-a-tête shows that, on particular occasions, something more must have been added to it. A faculty like this would, in some hands, have made a fortune; and I understand that great offers were made to him for the exercise of his art abroad. But hunting was the passion of Sullivan. He lived at home in the style most agreeable to his disposition, and nothing could induce him to quit Duhallow and the fox-hounds."

Mr. Castley, a writer in the *Veterinarian*, witnessed the total failure of the younger Sullivan. He says—"We have in the regiment a remarkably nice horse, called Lancer, that has always been very difficult to shoe; but seven or eight years ago, when we first got him, he was downright vicious in that respect. When the regiment was stationed at Cork, the farrier-major sought out the son of the celebrated 'Whisperer,' and brought him up to the barracks, in order to try his hand upon Lancer, and make him more peaceable to shoe; but I must say this person did not appear to possess any particular controlling power over the animal, more than any other man. Lancer seemed to pay no attention whatever to his charm; and, at last, fairly beat him out of the forge. Time, however, and a long perseverance in kind and gentle treatment, effected what force could not. The horse became pretty quiet to shoe."

Did we not know, from the recent performances of Mr. Rarey, that such things are possible, it would seem almost incredible, that a man being left only one night in King Pippin's stable, should have produced such an alteration in that animal's ferocity. It is said some have the power of disarming the rage of the most savage dogs; and the "Whisperer" appears to have found out the same charm for the vicious horse.

"Jumper" seems to have had extraordinary power over other animals besides the horse; for he is said to have tamed a buffalo for the saddle, for Mr. Tempest, and a pair of reindeer for Lord Fitzwilliam. The manner of his treatment seems sufficiently intelligible. His charm consisted chiefly in fearlessness and brute force. He would generally try rough measures first; and in his perilous encounters with some of these troublesome animals, had nearly every bone of his body fractured. "Jumper," however, seemed to have some sort of magic about him; for it is said, when he had, by dint of punishment, striven in vain to conquer an unruly horse in the market-place of Wakefield, he alighted, stood on the near side of the animal, brought the head almost back to his off-shoulder, by forcibly pulling at his off-rein, and then sternly gazed at him over the withers for two or three minutes. The animal began to tremble, and broke out in a profuse perspiration. "Jumper" then loosened his hold of the rein, and patted and caressed him, and was immediately followed by him round the market-place, perfectly subdued. "Jumper" is described as having been employed in the contested elections for Yorkshire, covered with orange plush from top to toe, and scampering in every direction over the
MODERN VETERINARY PRACTICE.

[MR. RAREY.

The system of Mr. Rarey now demands our attention.

The taming method pursued by this American gentleman has been considered very successful; at least, it has received an extensive patronage in this country. He begins to make the acquaintance of the colt when at pasture, and by the mildest means, and, almost without any physical signs, entices the animal to enter a stable, barn, or out-house, in the immediate neighbourhood. An old horse is then let in, and the colt is, without any stir, surrounded, and left alone with the operator.

Nothing of life is then permitted to be in his presence save the man who has to tame him, and who strives to absorb the whole of the attention of the animal. Gentleness becomes the rule. Everything calculated to excite fear, or raise alarm, is discarded from the appearance and conduct of the man, who approaches the animal holding out his hands, and speaking to him in the softest tones. By-and-by the colt gains confidence, and will approach him, and smell his hands, when he must take the opportunity of first stroking the nose, and then the face, cheeks, and neck. When the colt has yielded itself entirely to this kind of treatment, a leathern belt is very quietly passed up and on to his head, which is the first step towards real subjugation. For this purpose a rope halter should not be employed, being objectionable because of its coarseness. When this is accomplished, a plain, smooth snaffle-bridle, with a moderate-sized snaffle-bit, is passed into the mouth, and fitted to the head. All this must be done without hurry, and nothing whatever should be allowed to move or agitate the feelings of the animal.

When this has been done, the next point is to handle, with the utmost gentleness, the neck, shoulder, and near fore leg. After this, the Shank is taken in the palm of the hand, and the foot raised from the ground. This movement is assisted by pressing the back snow with the finger and thumb, or by turning the colt's head and neck well to the left. When the foot has been once stirred, the operation must be repeated until the animal will permit the foot to be bent near to the elbow-joint, and to be kept for a time in that position.

The body is next handled, the hand passing along to the hind quarter and leg. The hind

county. Sometimes he would exchange this costume for a bearskin, enveloped in which, and mounted occasionally on a buffalo, he was indeed a most formidable looking object.

This power of fixing the eyes upon the face of any animal, seems to have an almost overwhelming effect of bringing them into a state of subjugation. It was but the other day that we read, in an American paper, of a Yankee exhibiting himself as a snake-charmer. The manner in which he proceeded was thus detailed—"A tall, bony, Yankee-looking foreigner, last from California, made his appearance in Virginia, with a box of snakes—rattlesnakes, mocassins, black snakes, vipers, &c. He collected a crowd around him, though at a respectful distance, and grasping with both hands a bunch of snakes, coiled them round his neck, and thrust them into his bosom, as if they were strands of silk or cotton. Their twistings and turnings seemed to give him pleasure, while the by-standers were filled with very opposite emotions. He professes to tame his savage friends by means of mesmerism, and thus fights the rattlesnake with his own weapon. Some in the crowd suggested that he should take a wild, untamed snake, and show his power over it, which he agreed to do for twenty-five dollars. This sum was readily subscribed, and a rattlesnake, caught the day before, was soon procured. The operator examined him with some caution, but presently turned the box over, and threw the venomous reptile upon the green sward. He kicked him about several times, caught him by the tail, and threw him back and forth, and finally seized him in the middle, and held him at arm's length. The snake turned his head towards him, and their eyes met; the latter fixed his gaze steadily upon the snake, and kept it so for several minutes, when he suddenly coiled it round his neck, thrust it in his bosom, as he had done the others, and the snake seemed entirely docile. Two days after he repeated his experiment, for twenty dollars, on a large rattlesnake which had just been caught, and with similar results. A crowd of ladies and gentlemen witnessed the singular exhibition. It was painful to behold, though the individual seemed to have the most entire confidence in his ability to control the horrid animals."

The system of Mr. Rarey now demands our attention.

The taming method pursued by this American gentleman has been considered very successful; at least, it has received an extensive patronage in this country. He begins to make the acquaintance of the colt when at pasture, and by the mildest means, and, almost without any physical signs, entices the animal to enter a stable, barn, or out-house, in the immediate neighbourhood. An old horse is then let in, and the colt is, without any stir, surrounded, and left alone with the operator.

Nothing of life is then permitted to be in his presence save the man who has to tame him, and who strives to absorb the whole of the attention of the animal. Gentleness becomes the rule. Everything calculated to excite fear, or raise alarm, is discarded from the appearance and conduct of the man, who approaches the animal holding out his hands, and speaking to him in the softest tones. By-and-by the colt gains confidence, and will approach him, and smell his hands, when he must take the opportunity of first stroking the nose, and then the face, cheeks, and neck. When the colt has yielded itself entirely to this kind of treatment, a leathern belt is very quietly passed up and on to his head, which is the first step towards real subjugation. For this purpose a rope halter should not be employed, being objectionable because of its coarseness. When this is accomplished, a plain, smooth snaffle-bridle, with a moderate-sized snaffle-bit, is passed into the mouth, and fitted to the head. All this must be done without hurry, and nothing whatever should be allowed to move or agitate the feelings of the animal.

When this has been done, the next point is to handle, with the utmost gentleness, the neck, shoulder, and near fore leg. After this, the Shank is taken in the palm of the hand, and the foot raised from the ground. This movement is assisted by pressing the back snow with the finger and thumb, or by turning the colt's head and neck well to the left. When the foot has been once stirred, the operation must be repeated until the animal will permit the foot to be bent near to the elbow-joint, and to be kept for a time in that position.

The body is next handled, the hand passing along to the hind quarter and leg. The hind
leg must now be raised as high as possible, and the tail well handled. The same process is then to be carried out on the left side of the colt, which concludes the handling. Should any disposition to restiveness be exhibited on the part of the colt, both of the fore legs must be immediately strapped up, and the animal brought to the ground upon his knees. If there is not about the depth of a foot of straw on the ground, knee-caps should be employed for protection. For the near fore leg, the strap should be an inch in breadth, and about three feet in length. When the colt is strapped well up, he is induced to move about on three legs, the bridle being used in such a manner as to effect this. When the animal becomes reconciled to this condition, the handling of the body and hind legs is again proceeded with. When this is borne with sufficient patience, a surcingle or roller should be fastened round the body. Should there be any restiveness shown by the animal while bending up the near fore leg alone, the off fore leg must at once be proceeded with.

The strap for this purpose must be about six feet in length, of the thickness of a strong rein, and about an inch or an inch and a quarter in width. It has a loop of three inches, or a metal D at one end. The loop or D is passed round the pastern of the off fore leg, the point of the strap taken through it, and the strap drawn tight to the pastern. The point of the strap is then carried within the surcingle or roller, and held tightly in the right hand. When the operator is desirous of raising the off fore leg, he inclines the head of the colt, by the aid of the bridle, to the right or left hand; and the instant the foot is removed, it is drawn up to the surcingle with force, and retained in that position, if possible. Generally speaking, a succession of violent plunges will succeed the fall, during the whole of which the person must retain his hold upon the leg; and, by placing his shoulder to the near forehand of the horse, with a strong bearing upon the off-rein to bend the head and neck outwards, so that the animal cannot collect with advantage his muscular force, he is soon compelled to yield up the contest.

When the animal has become quiet, the head, neck, body, limbs, and tail, should be handled in succession, until he is completely resigned to the process, and several opportunities should be taken to sit down upon the body, the forehand, and the hind quarters. Whilst this is going on, the saddle, without girths, or stirrups, may, for a short time, be placed on the body, or the harness laid upon the hind quarters. When you have to deal with a Zebra, or a horse as savage and wicked as "Cruizer"—a horse that can kick as fiercely from one leg, as others can from two—in that case, to subdue and compel him to lie down, have a leather surcingle, with a ring fastened to the belly-part; buckle the hobbles on the hind legs, and pass the ropes through the ring. When the horse is thrown down by strapping up the fore legs, the hind legs must be drawn close up to the ring in the surcingle. By-and-by the animal becomes quite tamed, and is thoroughly subdued. Gentleness, as far as it can possibly be practised, is the rule in Mr. Rarey's system; and in no case is the whip or stick used, if it can be avoided.

We now come to the system of Madame Isabelle, who received testimonials from almost all the continental authorities; and her success at the cavalry depot at Maidstone was unrivalled and unquestioned. She there broke-in a horse in six lessons, the property of Lord Granville; and the feat was accomplished in the presence of the Duke of Wellington, Lord Zetland, General Murray, and others. But what was more extraordinary, she caused the horse to be broken-in by the groom of Lord Granville, whom she instructed at the same time in equitation. On one occasion she had a mare, which had the bad habit of taking a branch of the bit between her teeth, which were by no means easily re-opened—and running away with her rider, according to her own good will and pleasure. She "stood over" before, and "out" behind; in consequence of the abuse of the "bridoon," her houghs were in very bad condition, although well-shaped. Madame Isabelle undertook, nevertheless, to bring them round and break her in, which certainly was not an easy task, when the temper and physical defects of the brute were considered. She succeeded, however, to a most extraordinary degree, and finally made her "coquette" as elegant an animal.
as could be seen. It was upon this animal—which Madame Isabelle considers rightly named, from the character above given, and other little incidental pleasantry, such as making the "clack of her teeth heard," and "exhibiting her foot in the air"—that the action of the "Surfaix Cavalier" was first tried; and the success obtained so proved the excellence of the system, that the fair "hippodamast" at once adopted it. In a work which she has published on the subject, she says—"I subsequently applied this action to horses of all ages and of every description, and discovered its infallibility, inasmuch as it succeeded without one single exception; but as this action was produced by the hand, it became very fatiguing, and also could not be produced with absolute certainty, because great tact was necessary. I then invented the 'Iron Cavalier.' I had well calculated all its desired effects, so as to produce exactly the action of the hand of an accomplished horseman, but with the great superiority arising from its fixed position, and its direct effects upon the salivary glands, the size of which it diminishes considerably. Thus with me the 'Surfaix Cavalier' solved the problem of breaking-in."

The following explanation of this lady's system is slightly altered from a review of it in The Field:

The "Surfaix Cavalier," the instrument by which Madame Isabelle produces such an effect, is the ordinary surcingle, which is put on over the saddle; and if the horse is shaped in the usual way—that is, where the loins are neither long nor weak, nor the withers very high—the saddle should be placed four inches behind the shoulder. There is a steel band inserted on either side of the girths, which extends from the near to the off side. The "Iron Cavalier" is a flat iron rod, nearly sixteen inches in length, which is fixed upon the centre of the "surfaix," or surcingle, upright, with a slight inclination forwards. There are four cross-bars on either side of the central rod, each about four inches long, terminating in circular holes for the insertion of the reins: each pair is nearly four inches apart from the others, the uppermost cross-bars being at the extremity of the central rod, which, as stated before, stands up nearly sixteen inches in height. The cross-bars range across the body of the horse; the circular holes are marked in pairs, 1, 2, 3, 4; No. 1 being the lower pair, No. 4 the upper. There are four reins, each about eight feet long, and at one end punched with holes marked from one to twenty-four, which are about 1/2 inches apart, giving a range for tight or loose reins. The bits are made to be effective, but not punishing. The cavvessons are lighter than usual; and, during the operation of breaking-in, the ordinary bit and snaffle reins are always put on, in addition to those belonging to the "Surfaix Cavalier."

These are the instruments used by Madame Isabelle; the "Iron Cavalier" being an improvement, and a very great one indeed, upon the old "dumb jockey," the effect of which was to act like a stiff and rigid band upon the ribs; while the action of the "Iron Cavalier" is only felt on the steel bands in the girth when the horse draws too tightly on the reins; the movement of these steel bands having the same effect as the rider's legs should have. With these remarks, we proceed to the instructions laid down by Madame Isabelle for the breaking a saddle-horse in twelve lessons, whether mounted or not.

There are twenty-seven lessons laid down as necessary for a horse to go through before he can be considered thoroughly broken-in. It will give a clear idea of the routine, to enumerate these in their order, as they are constantly referred to in the practical working out of the object. The first gives directions "to saddle and bridle" a horse, and place the "Surfaix Cavalier." No. 2, "to lift the fore legs; to free the action of the legs." This forms the important lesson of suppling a horse, or, as it may be literally termed, it is teaching him the use of his legs. No. 3, "to lead a horse to the riding-school." No. 4, "Pas d'équilibre decomposé, forward and backward." "This movement has for its object, to accustom the horse to the man, and to make him quiet and attentive, two things indispensable to proper breaking; to habituate him to the support of the bit, and the action of his jaws upon it; to divide his powers equally and regularly; to 'lead' with the proper foot in all his paces; to prepare him for the gallop, and to rein back readily." Nos. 5 and 6, "to bring a horse to the knowledge of the whip
and the long whip." Nos. 7 and 8, "to bring a horse to the knowledge of the spur, and to start by diagonal action." Nos. 9, 10, 11, and 12, are respectively "the flag, the drum and pistol shot, the music, and the sabre lesson." No. 13 is headed "left-about—right-about." Nos. 14 and 15, "pirouette on the forehead and on the haunches." Nos. 16, 17, 18, 19 are for "movements of the two pistes or tracks," which is effected by teaching a horse to cross the near legs over the off legs, taking generally an oblique direction. This movement is commonly called the "passage," incorrectly, according to Madame Isabelle. No. 20, "to start at a walk and at a trot!" No. 21, "to produce a noble carriage," No. 22, to "rein back" a horse; No. 23, "to teach the effects of the reins on starting at a gallop!" No. 24, to "rassembler" a horse. This exercise, with No. 2, are the two principal ones for what may be termed putting a horse on his legs. No. 2 is to make the horse's limbs supple by teaching him to lift his legs properly. To "rassembler" may be called keeping a horse together. The horse's croupe is placed against a wall, so that he cannot go back; and in this position, by means of the whip and the click of the tongue, he is made to move all his legs readily. Nos. 25 and 26 are jumping and mounting lessons; and No. 27 is the climax of all—the Riding Lesson.

In reference to these lessons, Madame Isabelle quaintly observes—"If it is not possible to have a riding-school—a courtyard, a corner of a garden, or even the highway will suffice for want of a better substitute." And it is stated as a positive rule, that "all the lessons should be an hour and a-half long during the whole of the breaking-in." In the first lesson, after saddling and placing the "Surfaix Cavalier" on, the reins must be fixed in the first holes, and the horse is exercised in No. 5, the whip lesson; No. 4, the pas d'équilibre decomposé; and in No. 14, the pirouette on the shoulders. In the second lesson, the bit reins are fixed in the second holes, the snaffle reins in the fourth holes. In addition to those exercises in the first, the horse is put to No. 16, the movement of the two pistes, and No. 20, the starting at a walk or a trot. In Lesson 3, the four reins are fixed in the seventh holes; and No. 17, the movement of the two pistes with the lunge and the whip, and No. 22, the "rein back," are brought into play. In Lesson 4, the four reins are fixed in the eighth holes. The horse is taught No. 6, "the knowledge of the long whip," and No. 18, the movement of the two pistes with diagonal action. In Lesson 5, the four reins are fixed in the tenth holes. The horse is made acquainted with the use of the spur. He is also made to "rassembler" (No. 24), and to go through No. 13 and No. 18. In the sixth lesson, the four reins are fixed in the twelfth holes; and Lessons Nos. 8, 21, ... 23 are added to the operations. In the seventh lesson, the reins are fixed in the fifteenth holes, and all the preceding operations are repeated. In Lesson 8, the four reins are fixed in the sixteenth holes, and the horse is "rassembler" and "rein back," and then is put to No. 19, the movement of the two pistes, the body being bent to the side to which the horse moves; but for this the reins are changed, the near bit and snaffle reins are fixed in the eleventh holes, and the off bit and snaffle reins in the sixteenth. In the ninth lesson, the reins are fixed in the eighteenth holes. The horse goes through all the preceding exercises, and is now taught to jump, No. 25. The three last lessons are devoted to repetitions, the only difference being in the reinings up; and the horse is then considered thoroughly broken-in and fit for the riding lesson—when, instead of the "Iron Cavalier," a soldier appears in the saddle, and every direction is given for teaching him equitation.

We have thus entered somewhat minutely into the system of Madame Isabelle, in order to show of what it consists. The directions are very minute; so much so, indeed, as in some cases to appear not to be required. But it has been proved by experience, that this aggregate of minute points is essential for realising the great object—namely, the speedy and perfect breaking-in of the horse. Of the horses in this country, Madame Isabelle observes, that the English use them, but do not break them in, and thus it is that so many are rendered vicious; and, if the cause is sought, "it will be seen that it has arisen, amongst the greatest number of them, from the injustice and brutality of which they have been the victims"—an additional evidence to the fact, that gen-
tleness or humanity, whether applied to man or beast, is a much better breaker-in than cruelty or barbarity. This new system offers every advantage that can be desired; it breaks in the horse quickly, without fatiguing him in the least; develops his powers, enlarges his action, increases his speed; renders him supple and elegant, gives him a perfect mouth, and makes him also docile and confident with men. There is also another very material point—that "the breaking-in of the horse, and the instruction of the man are so intimately connected, that while training the animal, the man cannot fail to teach himself."

We will now proceed to remark upon some of the most prominent vices of the horse.

When a horse begins to gib, persuasion should be first tried; and, afterwards, reasonable coercion, but no cruelty; for the brutality which is often exercised in attempting to compel a gibbing horse to throw himself habitually in the collar, never yet accomplished the purpose. Such an animal may be put in an omnibus as a wheeler, and particularly as the near-wheeler; or in the middle of a team at agricultural work; and in these situations he might be serviceable, but nowhere else. It will be useless for him to attempt to gib there, for he will be dragged on by his companions whether he will or not; and finding the inutility of resistance, he will soon be induced to work as well as any other in the team. This reformation will last while he is thus employed; but, like restiveness generally, it will repossess him when he returns to his former occupation. Some instances of complete reformation have taken place; but they are the exceptions to the rule.

When a horse, not accustomed to gib, betrays a reluctance to work, humanity will demand that some examination should take place, before measures of severity be resorted to. Sometimes the withers are wrung, and the shoulders sadly galled; and the pain, which, even with a fair draught, may be intense on level ground, becomes insupportable when going up a steep ascendency. These things should be observed, and, if possible, rectified; for, under such circumstances, severe punishment might produce obstinacy and vice, but not willing obedience.

A horse, with raw shoulders, or that have frequently been so, will not start with a cold collar. When the collar has acquired the warmth of the parts on which it presses, the animal will go without reluctance. Some determined gibbers have been reformed by constantly wearing a false collar, or strip of cloth round the shoulders, so that the coldness of the collar should never be felt; and others have been cured by keeping on the collar night and day, although the animal is not able to lie down so completely at his ease, as without it; and this a tired horse ought always to be able to do. When an animal gibs at his work, it has sometimes been useful to line the collar with cloth instead of leather; the perspiration is more readily absorbed; the substance which presses on the shoulder is softer, and it is more readily eased off at a tender place.

Biting may often be the consequence of natural ferocity; but it is a habit frequently acquired from the foolish and teasing play of grooms and stable-boys. When a horse is tickled and pinched by thoughtless and mischievous youths, he will first pretend to bite his tormentors. By degrees he will proceed farther, and actually bite them; and very soon after that, he will be the first to challenge to the combat, and, without provocation, seize some opportunity to gripe the incautious groom; and then, as the love of mischief is a propensity too easily acquired, this war which commenced half playful and half in earnest, will become habitual to him, and will degenerate into absolute viciousness. Nothing can here be done in the way of cure. Kindness would aggravate the evil, and no degree of severity will correct it. Prevention is in the power of every proprietor of horses. While he insists on gentle and humane treatment of his animals, he should systematically forbid this horse-play. It is that which can never be considered as operating as a reward, and thereby rendering the animal tractable; nor does it increase the affection of the beast for his groom, because he is annoyed and irritated by being thus incessantly teased.

Kicking, as a vice, is another consequence of the culpable habit of teasing the horse. There is no cure for this vice; and the owner of kicking horses cannot be justified in keeping them. "I have seen," says Professor Stewart, in his Stable Economy, "biters punished until
they trembled in every joint, and were ready to drop, but have never, in any case, known them cured by this treatment, if by any other. The lash is forgotten in an hour, and the horse is as ready and determined to repeat the offence as before. He appears unable to resist the temptation; and, in its worst form, biting is a species of insanity." The system of Mr. Rarey, however, might be tried. Some acquire a habit of kicking at the stall, and particularly at night, from mere irritability and fidgetiness. This is productive of considerable inconvenience, as disturbing the other animals; and frequently the kicker does himself some injury. Mares are more subject to these freaks than horses. This is a habit very difficult to correct. We have seen it attempted by fastening a thorn-bush, or a piece of furze against the partition or post. When the horse finds himself pricked by the bushes, it has a tendency to prevent his kicking, and perhaps, in the end, may cure him of this very disagreeable and dangerous habit. Should this method, however, fail, recourse is had to the log, though the legs are often not a little bruised by it. A rather long and heavy piece of wood, attached to a chain, is buckled above the hock, so as to reach about half-way down the leg. When the horse attempts to kick violently, his leg will receive a severe rap from the log, and the repetition of the blow may induce him to be quiet.

Kicking in harness, however, is a much more serious vice, and those horses that are so fidgety in the stable are the most apt to do this. From the least annoyance about the rump or quarters, some horses will kick most violently, and destroy everything within their reach. Cautions may certainly be used. If the shafts are very strong and without flaw, or if they are plated with iron underneath, and a stout kicking-strap used, which will barely allow the animal the proper use of his hind limbs in progression, but not permit him to raise them sufficiently for the purpose of kicking, he may be prevented from doing mischief. Still there may be possibility of accident; the strap may break, and extreme danger may ensue. A horse that has once begun to kick, whatever may have been the original cause of it, can never be depended on again; and he will be very unwise who ventures to sit behind him. For this vice Mr. Rarey's system has proved a thorough remedy.

Restiveness on being Mounted.—When the difficulty of mounting arises not from eagerness to start, but from unwillingness to be ridden, the sooner such a horse is disposed of the better. He may be conquered by a determined rider, but a skilful horseman alone will manage him; and even he will not succeed without many, and even dangerous contests. In the frequent strapping up of the near fore leg, however, a remedy has been found for this vice.—Mr. Rarey's system is here again recommended as a complete specific.

REARING

Sometimes proceeds from mere playfulness, carried to an unpleasant and dangerous extent; but it is oftener a vice, and consists in a desperate effort to unseat the rider. Sometimes it may be the result of using a deep curb and sharp bit. Some of the best horses will contend against this curb; and if the rearing proceeds from this cause, it may be prevented by using a snaffle bridle. It is otherwise a vice of such a dangerous description, that no rational man would think of mounting a horse addicted to it a second time.

The horse-breaker's remedy of pulling him backward on a soft piece of ground, is not only a dangerous, but a brutal one. Many animals have been injured in the spine, and others have broken their necks, by being thus suddenly brought over; while even the horse-breaker, who fears no danger, is not always able to extricate himself from the falling horse. Some animals, however, will be thoroughly tamed by a persevering system of soothing lessons, in which the voice of the trainer must be made familiar to him. He will then desist from his habit, and cease to rear the moment he is spoken to.

RUNNING AWAY.

Some headstrong horses will occasionally endeavour to bolt with the best riders. Others, with their wonted sagacity, will endeavour to dislodge the timid or unskilful. Some are hard to hold, or bolt only during the excitement of the chase; others will run away, prompted by a vicious propensity alone. There is no cure for this. The method which
affords any probability of success, is to ride with a strong curb and sharp bit; to have the horse always firmly in hand; and, if it will run away, and the place will admit of it, to give him (spurring neither curb, whip, nor spur) a great deal more running than he likes. Thoroughly trained horses, however, have no habit of this kind.

**VICIOUS TO CLEAN.**

There are a great many horses quiet to ride that are very difficult to clean. The origin of this is, probably, some maltreatment. In young animals, the skin is very delicate. If they have been curried with a too sharp comb, or rubbed too hard with an uneven brush, the recollection of the torture they may have felt makes them impatient, and even vicious, during every succeeding operation of the kind. Many grooms, likewise, seem to delight in producing these exhibitions of unceasing and vice; although when they are carried a little too far, and endanger the limbs of the grooms, the animals that have been most aggravated into these exhibitions of irritation are brutally kicked and punished.

This, however, is a vice which may be conquered. If the animal is dressed with a light hand, and whipped rather than brushed, and the places where the skin is most sensitive are avoided as much as thorough cleanliness will allow, he will gradually lose the recollection of former ill-treatment, and may become tractable and quiet to be cleaned. Strapping up the fore leg is a plan now adopted for the cure of this vice.

**VICIOUS TO SHOE.**

Nothing can be more annoying to a traveller than having a horse of this description. Meeting with an accident on the road, which demands the attention of the smith, this functionary is applied to, and, necessarily, dislikes the job as much as the traveller would himself. In nine cases out of ten, this vice has been caused by want of patience, and by injudicious management at the commencement of the shoeing of the horse; and it is, in reality, a very serious vice. It not only exposes the animal to occasionally severe injury from his own struggles, but also from the correction of the irritated smith, whose limbs, and even life being in jeopardy, is sometimes a little too heavy-handed in his mode of correction. Such a horse is very liable, and without any fault of the smith, to be pricked and lamed in shoeing; and if the habit should be confirmed, and it becomes necessary to cast him, or put him in the trevis, the owner may be assured that no long time will elapse before some formidable and even fatal accident will take place. If, therefore, mild treatment will not correct the vice, the animal cannot be got rid of too soon. “Horses, however, that have been vicious for a lifetime, are rendered quiet to shoe in one, two, or three lessons of taming. Indeed, upon the first instance of being thrown down, and thoroughly handled while in the horizontal position, the smith can shoe them with the greatest ease.”

Horses have many unpleasant habits in the stable and on the road, which cannot be said to amount to vice, but which materially lessen their value.

**CRIB-BITING.**

The only remedy for this vice is a muzzle, with bars across the bottom, wide enough to enable the animal to eat his corn and pull his hay, but not to grasp the edge of the manger. If this be worn a very long time, the horse may, possibly, forget the habit; but, in the majority of cases, the desire returns with the power of gratifying it.

Most of the other bad habits and vices of the horse, have been remarked upon in their appropriate places in previous portions of this work.

This is the proper place to notice Dr. Buntings's patent break for harness horses, which is, perhaps, the most complete invention that has yet been made public for the purpose of subduing vicious horses, and the training of colts. "The principle," says the editor of *The Horse*, "is the same as that in the old thrashing machine, in which horses are placed between poles from a centre, and driven round in a circle. Dr. B. has improved upon the machine by the addition of a cart, or carriage, which is fixed to the end of each pole, &c., having strong bars of wood, of about fourteen feet in length, placed at their extremities. These bars are made *to be* movable, to admit the horse between them; and to these bars the
horse is strapped with strong straps above and below. The driver sits upon one of the poles, and, with strong driving reins attached to the horse, and a good whip, he can break in one or more horses with the utmost ease. Dr. Bunting’s plan, in combination with that of Mr. Harey, will meet every case of restiveness that can enter into the perverse disposition of any horse, because it combines the several systems of coursing, driving, and, if necessary, riding also, at one and the same time, by the addition of a stable-leg in the saddle, provided the leg be furnished with post-boy’s leather guards to protect the limbs from being crushed against the poles, without the possibility of danger or mischief to the animal through plunging, rearing, or kicking; since the weight of the wheels, and the strength of the apparatus, will immediately exhaust his strength for evil, and prevent that last resource of vice, the throwing down of himself. By these means any description of horse can be broken-in with the utmost facility, and with much greater quickness than has ever yet been attained. The slug can be roused, the impetuous restrained, and the kicker and the biter will soon be convinced of the uselessness of their utmost efforts. This apparatus can be made to hold several horses at the same time. A common capstan-head, to move backwards as well as forwards, will answer the purpose. Dr. Bunting has found that poles, of seven yards in length, are the most appropriate for the machine, since longer poles would be too elastic, and shorter ones would too much circumscribe the size of the circle.”

CHAPTER XXXVIII.

WEIGHTS AND MEASURES.

The weights and measures used in the compounding of medicines, are troy weight and wine measure, which are divided and characterised as shown in the subjoined tables.

**Troy Weight.**

The Pound (lb.) contains 12 ounces. 3 xij

" Ounce . . . 8 drachms. 3 viij

" Drachm . . . 3 scruples. 9 iij

" Scruple . . . 20 grains. gr. xx

**Wine Measure.**

The Gallon (longum) contains 8 pints. viij

" Pint . . . 16 fluid ounces. fl. 7 xij

" Fluid ounce . 8 fluid drachms. fl. 5 viij

" Fluid drachm . 60 minims. • ml. lx

**Acacia Gummi—Gum-arabic.**

Gum is a thick, transparent, tasteless fluid, which exudes from certain species of trees, and is adhesive, and gradually hardens without losing its transparency. It is chiefly obtained from different species of the mimosa, particu-

**M. Nilotica, a native of Egypt and Arabia, whence it takes the name of gum-arabic. Its specific gravity is about 1.4. It is not changed by exposure to the air, but is deprived of its colour by the action of the sun. By heat it becomes soft, and is speedily reduced to the state of charcoal, which enters largely into its composition. Its constituent parts are carbon, hydrogen, and oxygen, with smaller proportions of nitrogen and lime. The oxygen is much less in quantity than the saccharine matter.**

Gum readily dissolves in water; and the solution, which is thick and adhesive, is known by the name of mucilage. It is soluble also in the vegetable acids. Sulphuric acid decomposes it, and converts it into water, acetic acid, and charcoal. With the assistance of heat, muriatic acid and nitric acid produce a similar effect. It is insoluble in alcohol and ether. Such are the chief properties of gum-arabic, which is gathered in July and August.

**Medicinal Uses.—Mucilaginous, chiefly used to form a vesicle for the exhibition of active**
remedies; one to two ounces being dissolved in about a pint and a-half of water.

Acidum Aceticum—Acetic Acid—Vinegar.

Vinegar is a liquid of a reddish or yellowish colour, having a pleasant sour taste, and an agreeable odour. Its specific gravity varies from 1.0135 to 1.0251; and it differs also in its other properties, according to the liquid form in which it has been procured. It is very subject to decomposition; but Scheele discovered, that if it is made to boil for a few moments, it may be kept afterwards for a long time without alteration. Besides acetic acid and water, vinegar contains several other ingredients, such as mucilage, tartar, a colouring matter, and often also two or more vegetable acids. When distilled at a temperature not exceeding that of boiling-water, till about two-thirds of it have passed over, all these impurities are left behind, and the product is pure acid diluted with water.

Medicinal Uses.—Very useful in sprains or bruises. Equal parts of boiling-water and cold vinegar form a good fomentation. Extract of lead or barysulphate may be added with advantage. As an inward remedial agent vinegar is rarely used, except in large doses, and even then it has very little power.

Acidum Arsenicosum—Arsenic.

As some veterinarians still continue to use this mineral as a tonic, we introduce it here. In the metallic state it is of a bluish-white colour, subject to tarnish, and to become first yellowish, then black, by exposure to air. It is brittle, and, when broken, exhibits a laminated texture. Its specific gravity is 5.763. In close vessels it sublimes entire at 356° Fahr., but burns with a small flame, if respirable air be present.

Medicinal Uses.—As a tonic, of from ten to twenty grains daily; but it is not a safe medicine. It is used also to cure ulcers. But there are both better tonics and safer caustics to be found.

Acidum Muraticum—Muriatic Acid—

Spirit of Salts.

When equal volumes of hydrogen and chlorine gases are mixed and exposed to light, they combine and produce a sour compound, commonly called muriatic acid gas, or, in conformity to more modern nomenclature, hydrochloric acid gas. Muriatic acid may also readily be procured by acting upon common salt with sulphuric acid; the evolved gas must be received over mercury. It was first obtained pure by Dr. Priestley, but its composition was discovered by Scheele, and afterwards most ably investigated by Davy. Muriatic acid gas extinguishes flame; is readily absorbed by water, which takes up 480 times its bulk, and has a specific gravity increase from 1 to 1.210. Thus dissolved in water, it forms the liquid muriatic acid or spirits of salts; and may easily be procured by distilling a mixture of dilute sulphuric acid and common salt, as directed in the London Pharmacopoeia. The marine acid in commerce has a straw colour; but this is owing to accidental impurity; for it does not contain in the acid produced by the impregnation of water with the aeriform acid. The muriatic acid is one of those longest known, and some of its compounds are among those salts with which we are most familiar. It should be kept in stoppered bottles, and the proof of its goodness is in its weight.

Medicinal Uses.—Caustic applied externally, and the best we have in every case where a caustic is required. It is most commonly used as a solvent for oxymuriate of mercury, in the liquor hydrargyris oxymuriates.

Acidum Nitricum—Nitric Acid—Aqua Fortis

The two principal constituent parts of our atmosphere—oxygen and nitrogen gases—when in certain proportions, are capable, under particular circumstances, of combining chemically into one of the most powerful acids—the nitric. If these gases be mixed in a proper proportion in a glass tube about a line in diameter, over mercury, and a series of electric shocks be passed through them for some hours, they will form nitric acid; or, if a solution of potash be present with them, nitrate of potash will be obtained. The constitution of this acid may be further proved, analytically, by driving it through a red-hot porcelain tube, as thus it will be decomposed into oxygen and nitrogen gases. For all practical purposes, however, the nitric acid is obtained from nitrate
of potash, from which it is expelled by sulphurous acid.

Take Dried Nitrate of Potash . 2 lbs. 

" Sulphuric Acid (by weight) 2 "
Mix them in a glass retort; distil the nitric acid off by means of a sand bath, till a red vapour arises; then having added another ounce of the dried nitrate of potash, continue the distillation. When these are heated together, a double decomposition takes place. The dry sulphuric acid unites to the potash, and forms sulphate of potash of what remains in the retort; whilst the nitric acid disengaged, unites with the water, rising in the state of vapour: these become condensed in the receiver, and form liquid nitric acid.

Medicinal Uses.—Caustic and stimulant; as the former, it is applied alone; as the latter, in combination with tar. It destroys all fungous excreances by deadening them, and making them slough off.

Acidum Hydrocyanicum—Prussic Acid.

Prussic acid, in chemistry and the arts, is one of the most important of the acids. It was discovered by accident about the beginning of the last century, by Diesbach, a chemist of Berlin. This gentleman, wishing to precipitate a decoction of cochenile with an alkali, got some potash on which he had distilled several times his animal oil; and as there was some sulphate of iron in the decoction, the liquor instantly exhibited a beautiful blue in the place of a red precipitate. Hence he saw the method of producing the same substance at pleasure; and it soon became an object of commerce, and obtained the name of Prussian blue, from the place where it was discovered. This substance is now formed, chiefly, during the decomposition of animal substances in high temperatures. In a concentrated state it is a deadly poison, and a few drops of it will kill a large animal.

Medicinal Uses.—A powerful sedative, and admirable in allaying the excitement of the nervous system. "In doses of six drops," says Mr. Youatt, "largely diluted, it abates both pulmonary and gastric irritation. It may be worth trying in the form of enema, in cases of tetanus. It may also be given by the mouth in the same disease. The author of this work was the first who applied the hydrocyanic acid, for the purpose of allaying irritation of the skin in dogs. It seldom fails of producing the desired effect, and is similarly effective in subduing itchiness and mange in the horse."

Acidum Sulphuricum—Sulphuric Acid—Oil of Vitriol.

Sulphuric acid is generally procured by burning a mixture of sulphur and nitre in chambers lined with lead. The sulphur burning in the atmospheric air of the chamber, forms sulphuric acid gas. The nitre gives rise to the nitric oxide, which, with the oxygen of the air, produces nitrous acid gas. These two gases, from the moisture present, form a white solid, which is instantly decomposed in the water, when the nitrous acid reverts to the state of nitre oxide, having transferred one additional proportion of oxygen to the sulphureous acid, forming sulphuric acid, which uniting with the water, forms liquid sulphuric acid. It is a liquid somewhat of an oily consistence, transparent and colourless as water, without any smell, and of a very strong acid taste. When applied to animal or vegetable substances, it very soon destroys their texture.

Medicinal Uses.—Caustic and stimulative, applied externally, but not very often used alone, entering more into combinations.

Alumine et Potassae Super Sulphas—Super Sulphate of Alum and Potash.

This is a salt of alum. Potash and sulphuric acid are found native in some places; but the greater quantity of the alum used in commerce is prepared from alum ores. By exposing these to atmospheric air, the oxygen unites to the sulphur of the sulphuret of iron present, and becomes converted into sulphuric acid, and then combining with the alumine, the alum effloresces. This is subsequently evaporated, and then set aside to crystallise.

Medicinal Uses.—Astringent; this is only used for the horse as an external application in the formula.

Aconiti Folia—Leaf of Aconite, or Monk's Hood.

This is a perennial plant, cultivated in our gardens, flowering in June, but found native
in the mountainous parts of Germany. It should be gathered when the flowers appear.

Medicinal Uses.—This, like all the other narcotics used by the human subject, produces no such effect in the horse. In doses of one and a-half to two drachms, repeatedly given, it will produce efforts to vomit, accompanied with much general irritation.

Adeps—Hog's Lard.

Medicinal Uses.—Emollient, and used for the formation of ointment.

Alcohol.—Rectified Spirits.

This spirit is sometimes given to revive a horse that is sinking from extraordinary exertion; but it must, indeed, be an extraordinary occasion when we would recommend its use.

Aloes Caballina—Horse Aloes are Cape Aloes.

Aloe Spicata—Spiked, or Socotrine Aloes.

Aloe Vulgaris Extractum—Common, or Barbadoes Aloes.

The general nature of these three kinds of aloes is nearly the same, the difference being only in the different proportions of the extracted gummy matter compared with the resinous. The smell and taste reside principally in the extracted matter as to their virtues, the resin being nearly inert.

The leaves of the plant are cut off, expressed, and the juice evaporated in the sun till of a fit consistence, which is then put into packages.

True Socotrine aloes are very scarce. They are brought to this country wrapped in skins, from the island of Socotra. Such as are now sold for Socotrine, is the produce of the spiked aloes of the Cape of Good Hope.

The term Caballina, applied to the Cape aloes, is for the sake of distinction, although it is believed that the same plant yields this, and what is now sold as Socotrine, differing only in quality. Cape aloes are imported in chests of two to four hundred pounds' weight each, enveloped in buffalo hides. The finest Barbadoes are brought in gourds, or calabashes, from the island of the same name, and contain from twenty to fifty-six pounds each. An inferior quality comes in casks.

Medicinal Uses.—Purgative and alterative; the first in doses of four to eight drachms, the latter in doses of one to three drachms. The effect of Cape aloes seems equal to any of the others.

Ammoniæ Muria.—Muricate of Ammonia, Sal Ammoniaci.

A saline concrete, formed by the union of muriatic acid with ammonia. It is obtained from several sources. First, found native; second, prepared from camels' dung; third, which is the principal, from soot, bones, animal matter, known to contain the volatile alkali, as horn, &c. The process is as follows. The animal matter is placed in an iron cylindrical still, to which is attached a leaden receiver, cooled by a refrigeratory, which is its cover, and contains about four inches in depth of water; heat being applied, distillation is allowed to go on. The oil which rises to the surface of the distilled liquor being removed, to the residue—which is impure alkaline solution—is added sulphuric acid, and a sulphate of ammonia is formed; to this is added common salt, when a double decomposition takes place, muriate of ammonia, and sulphate of soda, being formed through chemical agency. These being in solution, the last salt is crystallised, and the first sublimes into cakes.

Medicinal Uses.—Refrigerant, applied externally, dissolved in vinegar, in inflammatory swellings, when cold is the required object. It is now used internally, but it hardly merits a notice here.

[It may not be irrelevant to observe, that a solution of any neutral salt in water, lowers the temperature of it by robbing it of a portion of its caloric, to liquefy the salt; but the solution will acquire a mean of temperature equal to the surrounding medium in which it is placed, in the course of time, therefore it should be used as soon as made].

Anthemis—Camomile.

Medicinal Uses.—This is the mildest tonic in veterinary practice. It is given in doses of one or two drachms, to ascertain whether the febrile stage of the disease has passed away, and to suggest the administration of gentian, which is a more powerful tonic, and is frequently given to the horse.

349
Antimonii Sulphuretum—Sulphate of Antimony.

Medicinal Uses.—Alternative and vermifuge; but of very little effect. Much used amongst grooms, combined with sulphur and nitrate of potash. Dose from half an ounce to one ounce.

Antimonii Tartarizatum—Tartarised Antimony—Emetic Tartar.

Medicinal Uses.—Febrifuge in doses of half a drachm to two drachms, generally in combination with nitre, &c. Large doses will not, in the horse, produce nausea, even to the quantity of an ounce.

Anchusa Radix—Alkanet Root.
The root of a perennial plant, growing in the south of Europe.

Medicinal Uses.—Merely used for the sake of its colouring matter, which it readily yields to oils, fats, spirits, &c.; but not to water.

Argenti Nitras—Nitrate of Silver—Lunar Caustic.

Lunar caustic is the old name for nitrate of silver, melted and cast into cylindrical pieces about the size of small black-lead pencils, for the use of surgeons.

Take Silver . . . 1 oz.

" Nitric Acid . . . 1 fl "

" Distilled Water . . . 2 fl "

Mix the nitric acid with the water, and dissolve the silver with the mixture on a sand-bath; then gradually raise the heat until the nitrate of silver becomes dry; melt this in a crucible over a slow fire until ebullition ceases; then pour into moulds.

Decomposition.—Nitric acid is composed of oxygen and azote; and when the silver is dissolved, a portion of the acid is decomposed, its azote escaping into the air with the oxygen, which forms with it fumes of red nitrous acid gas. The oxygen of the decomposed acid unites with the silver to form into an oxide, whilst the undecomposed acid dissolves, and converts it into nitrate of silver.

Medicinal Uses.—Caustic. This appears to have given place to less expensive preparations, such as the nitric acid, and the sulphate of copper. It is, however, much to be preferred to the hot iron, or to any acid, for destroying the part in the horse, bitten by a mad dog. Next to the butter of antimony, it is the best application for the removal of fungus excrescences.

Bolus Armenie—Armenian Bole.

In mineralogy, bole is a mineral, found chiefly in Italy, Silesia, and the isle of Lemnos. It is generally of a dusky yellow or brown colour, of an earthy texture, and acquires a polish by friction. It has a greasy feel, and adheres strongly to the tongue. On being put into water it absorbs a little, and breaks into small fragments with a crackling noise.

Medicinal Uses.—Slightly astringent and absorbent. It is chiefly used for colouring ointments and powders, and for lowering the effect of other active remedies, as sulphate of copper and alum, when used as astringent powders, in case of grease, &c., &c.

Camphor.—Camphor.

This concrete juice is extracted from the wood of the laurus camphora. Pure camphor is white andpellucid, unctuous, of a bitterish aromatic taste, and of a fragrant smell. It is extremely volatile and combustible.

The roots of zedoary, thyme, rosemary, sage, the linula helleinum, the anemone, the pasque flower, or pulsa tilla, and other vegetables, give camphor by distillation. It is observable, that all these plants afford a much larger quantity of camphor when the sap has been suffered to pass to the concrete state by several months’ drying. Thyme and peppermint, slowly dried, yield much camphor; but the roots and branches of the camphor tree are its most natural produce.

Camphor is not soluble in water in any perceptible degree, though it communicates its smell to that fluid, and may be burned as it floats on its surface. Alcohol, ethers, and oils, dissolve it.

The addition of water to the spirituous or acid solutions of camphor instantly separates it.

Camphor has long been a valuable article in the materia medica, being one of the most efficacious diaphorotics, and much esteemed for its use in malignant fevers and epidemic diseases. Camphor acid is the result of the change effected on camphor by repeatedly distilling nitric acid from it.
It forms a variety of salts called camphorates.

Medicinal Uses.—Febrifuge, internally; stimulant, externally; in doses of one drachm to two drachms, combined with nitre and tartarised antimony. As an external application it is used in the compound soap liniment. Mixed with opium, it is now used by Mr. W. Spooner in cases of locked-jaw. The doses are from one to two drachms. Professor Morton considers it a narcotic. Combined with oil of turpentine, it is effective in relieving stiff joints after labour.

Cantharis—Blistering Fly.

Cantharides, or blistering flies, in the Materia Medica, are insects used to raise blisters, and differ in their size, shape, and colour. The largest are about an inch long. Some are of a pure azure colour; others of that of pure gold; and others, again, have a mixture of gold and azure colours, all brilliant and extremely beautiful. They are more common in hot countries, though they are occasionally to be met with in all parts of Europe, at some seasons of the year; particularly among wheat and on meadows, upon the leaves of the ash, the poplar, the willow, &c. They abound in Spain, Italy, and France, on several kinds of trees. Those from Spain are obtained by shaking the trees on which they are found, and catching them in a cloth spread underneath. They are then killed by the steam of boiled vinegar, and dried by the sun or stove. The active principle appears to reside in an oil which they contain.

Medicinal Uses.—Vesicant, applied in the formula unguentum cantharidis infusionum, &c. Recently the application of this fly has come into more general use. Combined with vegetable bitters, it is recommended as a stimulating tonic in cases of debility. It has also been applied to the curing of glanders. The dose is from five to eight grains, given daily; but when diuresis supervenes, it must not be used for a day or two.

Capsici Bacce—Capsicum Berries.

Capsicum, or Guinea pepper, is the fruit of a berry. There are five species, the principal of which are—1. Capsicum annum, the common long-podded capsicum, which is cultivated in our gardens. Of this there is one variety with red, and another with yellow fruit.—2. Capsicum baccatum, bird pepper, rising with a shrubby stalk, four or five feet high; the fruit grows at the division of the branches, standing erect; these are small, oval, and of a bright red, and form what is called Cayenne pepper.—3. Capsicum grossum, the bill pepper. The fruit of this is red, and is the only kind fit for pickling.

Medicinal Uses.—Valuable as stimulants, and highly to be recommended in cases of cold. The dose is from a scruple to half a drachm.

Carui Semina—Caraway Seeds.

These alone, or in a state of combination with ginger, are the best stimulants used in veterinary practice.

Catechu Extractum—Extract of Catechu—Catechu.

Catechu is a brown astringent substance formerly known by the name of Japan earth. It is a dry extract, prepared from the wood of a species of sensitive plant, the minosa catechu. It is imported from the East Indies. As a medicine it has been recommended as a powerful astringent, and a tincture of it is used for this purpose; but its aqueous solution is less irritating. Made into troches, with gum-arabic and sugar, it is an excellent preparation; and in this way is said much to assist the clearness of the voice, and to be remarkably serviceable in disorders of the throat.

Medicinal Uses.—Astringent. Dose from two drachms to four drachms, in combination with creta preparata. For wounds it is an excellent application, and with aloes quickens their healing wonderfully.

Creta Preparata—Prepared Chalk.

Chalk is a white, dry, calcareous earth. Where it is found at all, it is the preponderating substance, and may, therefore, be considered as characterising a peculiar species of mineral formation. It occurs in strata for the most part nearly horizontal, alternating with thin layers of flint nodules, and with the same irregularly dispersed through its substance. It contains in abundance the relics of marine organised bodies, such as echinites,
glossopectra, pectinates, &c., and also, not unfrequently, the hard parts of amphibiaous and land animals, as the heads and vertebrae of crocodiles, and the teeth of elephants. Its uses are very extensive. The more compact kinds are used as building stone, and are burnt to lime; nearly all the buildings in London being cemented with chalk-mortar. It is also largely employed in the polishing of metals and glass; in constructing moulds to cast metal in; by carpenters and others as a material to mark with; and by starch-makers and chemists to dry precipitates on, for which it is peculiarly qualified on account of the remarkable facility with which it absorbs water.

Prepared chalk is made by washing common chalk in water, and allowing the grosser particles, as sand, &c., to fall to the bottom; whilst the finer particles floating on the water, are poured off with it into another vessel, and then permitted to subside, and are afterwards made into nobs, and dried.

**Medicinal Uses.**—Absorbent, anti-acid. It is either given alone, or in combination with kino, catechu, &c., in quantities of from four ounces to six ounces in diarrhoea. To ulcers that discharge a thin and ichorous matter it is successfully applied.

**Copaiba—Balsam Copi**

*Copaiba,* or *balsam of copi* i, is a liquid resinous juice which comes from the trunk of the *copaiferum balsamum.* It is distilled in water, and yields a quantity of limpid essential oil.

**Medicinal Uses.**—Diuretic; but, from its expensiveness, it is little used, as its properties are little different from those of other diuretics.

**Crotoni Semina—Croton Seeds.**

The *Croton-nut* has only recently been introduced into veterinary practice, although, as a very strong purgative, it has been used in India from time immemorial. There are many species of the plant which produce the seeds, the principal of which are:—1. *The tinctorium,* which grows naturally in the south of France, and from which is made the turnsole used for colouring wines and jellies. This is made of the juice lodged between the emplacement and the seeds; and if rubbed on cloths, at first appears green, but soon changes to a purple. If these cloths are put into water they will dye it of a claret colour. The rags thus dyed are brought to this country, and sold under the name of turnsole.—2. *The secoferum,* or tallow tree, is about the height of the cherry tree; the leaves are heart-shaped, and of a deep red colour. The fruit is enclosed in a cover like the chestnut; and consists of three white grains, each having a capsule, and within that a stone. This stone is surrounded with a white pulp, which is not the tallow; for that is expressed from the kernels, and the Chinese make their candles of it.—3. *The aromaticum,* with heart-shaped serrated leaves, and an arborescent stem. The bark of this tree is the same with the *coscarilla* and *eleutheria.* It is a strong bitter, and has been used in intermittent fevers in preference to the Peruvian bark.—4. *The coscarilla* described by Dr. Wright, is the wild rosemary shrub of Jamaica; but its bark has none of the qualities with the preceding.—5. *The Tyleum;* one drop applied to the tongue acts as a powerful cathartic. This is the one that is used in horse-practice.

**Medicinal Uses.**—Cathartic, in doses, from ten to thirty grains in a ball. It appears from experiment from the meal, or rather cake, which remains in the press after the expression of the oil from the seeds, that the active principle does not reside so much in the oil as in a peculiar resin. Its effects are rather uncertain. On account of the rapidity of its operative power, it is given in staggers and locked-jaw. From twenty to forty drops put on the tongue of a horse produces purging; but the membrane of the mouth is often violently inflamed by it.

**Cupri Subacetatis.Ærugo—Subacetate of Copper—Verdigris.**

*Verdigris* is principally made in the south of France, by putting plates of copper among the residuum of the grape, after the expression of its juice. By frequently sprinkling them with water, and allowing the grape-stalks to ferment, a thick coating of verdigris is formed on the surface of each plate, and is scraped off by means of a knife, then put into bags, and exposed to the sun and air to dry.

**Medicinal Uses.**—Detergent and escariotic. It has been administered internally, but it is
a dangerous medicine. Externally it forms a
mild caustic. When boiled with vinegar and
honey, it makes the *Egyptiacum* of the farriers,
which is good in ulcerated mouth, but not so
good as some other remedies.

*Cuprum Sulphas*—*Sulphate of Copper—
Blue Vitriol.

This is produced by the union of sulphuric
acid and copper. It is also procured by wash-
ing copper pyrites, and exposing them to the
action of air and moisture. When required
for these purposes, it may be made in the
same manner as sulphate of zinc, by putting
pieces of copper into diluted sulphuric acid,
contained in a glass vessel, and when the eff-
ervescence has ceased, filtering the solution
through paper, and boiling it down till a
pellicle appears on the surface; then setting
it aside that crystals may form, which are to
be dried in bulbous paper.

*Decomposition.*—Concentrated, it does not
act on the metals at the ordinary temperature
of the atmosphere. These require to be diluted
when action goes on rapidly; the water is de-
composed, its oxygen unites to the copper,
and converts it into an oxide, which is dis-
olved by the sulphuric acid, and forms
sulphate of copper, whilst its hydrogen escapes
in the form of gas.

*Medicinal Uses.*—Tonic, internally; stimu-
lant and escharotic externally, given in doses
of from one to two drachms, combined with
ginger, as a general tonic, in the form of balls;
but when given, in cases of glands and farcy,
in doses of from four to eight drachms, it is
advisable to make it into a draught, by dissolv-
ing it in about two pints of water, and adding
an ounce of linseed meal to the solution. Its
value in these diseases, however, is almost
entirely considered to have ceased. Exter-
ially, it is applied either in solution or in
powder. When applied in solution, it is in
the proportion of two drachms to a pint, when
it acts as a gentle stimulant. An ounce dis-
solved in the same quantity converts it into a
mild caustic. For canker in the foot, the blue
vitriol is a good application.

*Digitalis Folia*—*Fox-Glove Leaf, or
Digitalis.*

Of the *digitalis*, or *fox-glove*, there are
several species, five of which are herbaceous,
bienial, and perennial plants. The herbaceous
species rise two or three feet high, crowned
with spikes of yellow, iron-coloured, or purple
flowers. The *canariensis*, or shrubby sort,
rises five or six feet high, having spear-shaped
rough leaves, the branches being terminated
with flowers growing in loose spikes. All the
species are easily raised by seeds. An oint-
ment made of the flowers of purple fox-glove
and fresh butter, is commended by some sur-
geons for serofulous ulcers. Taken inter-
ally, the plant is a purgative and emetic; and
is, therefore, only to be administered to
robust constitutions. An infusion of two
drachms of the leaf in a pint of water, given
in half-ounce doses, every two hours, till it
causes vomiting or purging, is recommended
in dropsy, particularly that of the breast. The
leaves are the part of the plant used medi-
cinally, which should be gathered just as the
plant is in flower, and dried quickly in the shade;
or, what is still better, secluded entirely from
light. Let them be powdered, and kept in
well-stopped bottles for use.

*Medicinal Uses.*—Sedative, given in doses of
from half a drachm to two drachms, in the form
of a ball. The effect of digitalis requires watch-
ning; although the over-dose will only lower the
vital energies of the patient in cases of intermit-
tent fever. In the form of tincture it is ex-
cellent for inflammation of the eyes; and as a
sedative it is nearly equal to opium. An infu-
sion of it has, also, been found serviceable in
mange.

*Extractum Belladonnae*—*Extract of Deadly
Nightshade.*

This is prepared by bruising the leaves of
the plant in a stone mortar, sprinkling a little
water on them, and then pressing out the juice
and evaporating. It must stand until it ac-
quires a thick consistency.

*Medicinal Uses.*—Stimulant. It is only
used as an application to the eye, to cure a
morbid contraction of the iris, or rather its
circular fibres, in quantities of from two to five
grains.

*Euphorbi Gummi Resinii*—*Euphorbium.*

The name of *resin* is used to denote solid
inflammable substances, of vegetable origin,
soluble in alcohol, usually affording much soot by their combustion. They are likewise soluble in oils, but not at all in water, and are more or less acted on by the alkalies. All the resins appear to be nothing more than volatile oils, rendered concrete by their combination with oxygen. Analysed by M.M. Gay Lussac and Thenard, resin was found to consist of

*Carbon.* 75-944
*Hydrogen.* 10-719
*Water.* 15-156.
*Oxygen.* 13.373

Hydrogen in excess, 8-9.

The resin of fir is known by the name of rosin. Its properties are well known. Its specific gravity is 1072. It melts readily; burns with a yellow light, throwing off much smoke. Resin is insoluble in water, either hot or cold, but very soluble in alcohol.

The plant which yields euphorbium is perennial, succulent, and shrubby. It is obtained by making incisions in the branches, from which a lartious gum exudes, and concretes into drops.

**Medicinal Uses.**—Stimulant. Rubefacient. It is used externally, entering into the compound *unguentum cantharidum*. Internally it is given as a diuretic, in doses of from five to six drachms, made into a ball, with soft soap. A preference, however, is given to the common liquid turpentine.

**Ferrum Sulfuratum.—Sulphate of Iron.—Copperas.**

*Copperas* is the green salt sulphate of iron; and the blue salt sulphate of copper is also sometimes called copperas.

**Take of Iron (by weight)**

8 oz.

**Sulphuric Acid**

8

**Water**

4

Mix the sulphuric acid with the water, in a glass retort, and to this add the iron in the form of filings. When bubbles cease to escape, filter the solution through paper, and evaporate over a slow fire, so that, as it cools, crystals may form. Having poured off the supernatant fluid, dry the crystals upon biblious paper.

**Gentiana.—Gentian.**

Of this plant there are many species. The most remarkable are the lutea, or common gentian, the root of which is an excellent stomachie bitter; and the lesser century.

**Decomposition.**—Water consists of oxygen and hydrogen, and a portion of it is decomposed by the action of the sulphuric acid and iron. Its oxygen unites to iron, converting it into an oxide of iron; before which the sulphuric acid will not act upon it, whilst its hydrogen being set free, escapes in the form of gas. The oxide of iron is then dissolved by the sulphuric acid, and sulphate of iron is formed.

**Medicinal Uses.**—Tonic; combined with ginger.—*Carbonate of Iron* is a mild tonic given in doses of from two to four drachms.—As a stomachic, and a tonic, gentian holds the highest place in veterinary practice. Four drachms of it, two of camomile, one of ginger, and one of carbonate of iron, make an admirable tonic ball. An application of an infusion of gentian to putrid ulcers is one of the best.

**Glycyrrhiza Radix.—Liquorice Root.**

The *glycyrrhiza*, or common liquorice shrub, has a long, thick, creeping root, striking several feet deep into the ground. It is an annual, with an upright, firm, herbaceous stalk, three or four feet high, garnished with winged leaves, of four or five pair of oval lobes, terminated by an odd one; and from the axillas, erect spikes of pale blue flowers in July, are succeeded by short, smooth pods. The root of this plant is the useful part, being replete with a sweet, balsamic, pectoral juice, which is either extracted, or the wood sold in substance. It is much used in all compositions for coughs, and disorders of the stomach; but by far the greatest quantity is used by brewers. The common liquorice is cultivated in most countries of Europe, for the sake of its root; but in Spain and Italy, and particularly in Sicily and Calabria, it makes a considerable article of commerce with this country. Liquorice also grows in great abundance in the Levant; and vast quantities of it are consumed there, in making a decoction which is drunk cold in the summer, in the manner of sherbet.

To prepare liquorice, the roots are boiled a long time in water, till the fluid acquires a deep yellow tincture; and the water at length evaporated till the remains assume consistency, when they are formed into sticks, which are packed up with bay leaves, in the same
order as received in England. The boiling requires the utmost care and precaution, as the juice takes an unpleasant smell and flavour, if burnt in the least degree. We introduce it here, not on account of any value it has in veterinary practice, but because, when dried and ground, it is used for adding to bulk, rather than for any other purpose.

**Medicinal Uses.**—Dramentic.

**Hydargyrum**—Quicksilver—Mercury.

Mercury is a metal, which, in our climate, is always fluid, but in intense cold it becomes solid, and then resembles silver in appearance, and is malleable. It is sometimes found native, but much more frequently combined with sulphur, when it is denominated cinnabar. It is separated from the sulphur by distillation with quicklime, or iron filings. It is obtained abundantly in the Austrian territories, and in South America, and has a great affinity for other metals. One hundred pounds of the ore give about one hundred and three pounds of quicksilver.

**Medicinal Uses.**—Only employed for making mercurial preparations.

**Hydargyri Oxymuriatis**—Oxymuriate of Mercury—Corrosive Sublimate.

Take of Purified Mercury (by weight) 2 lb. Sulphuric Acid . . . . 30 oz. Dried Muriate of Soda . . . 4 lb.

Boil the mercury with the sulphuric acid in a glass vessel, until the sulphate of mercury becomes dry. Rub this, when it is cold, with the muriate of soda, in an earthen mortar; then sublime in a glass, the heat being gradually raised.

**Decomposition.**—When sulphuric acid and purified mercury are boiled together, a portion of the acid is decomposed and separated into sulphurous acid oxygen; the former being dissipated in the gaseous state, the latter combines with the mercury, and converts it into peroxide; and this uniting with the undecomposed acid, a super-sulphate of peroxide, or bifer sulphate of mercury, is formed. To this the salt is added, when another decomposition takes place, as follows.

We consider salt as a compound of chloride and sodium. This, when heated with the bifer sulphate of mercury, is decomposed by it; the sodium is converted into soda by its combination with the oxygen from the mercury which is dissolved by the sulphuric acid, and forms sulphate of soda; whilst the chlorine unites with the mercury, and forms peroxyde or chloride of mercury.

**Medicinal Uses.**—Caustic, applied externally, either mixed with grease or in solution, as in the formula, liquor hydrargyri oxymuriatis.

**Iodine.**

Iodine has only recently been introduced into veterinary practice, but it has now obtained a high reputation. In the Manual of Pharmacy, by Professor Morton, the different combinations in which iodine may be used are described. Under the name of dimiodyde of copper, he describes it as an admirable tonic, if combined with vegetable tonics, and especially small doses of caustic bases. This combination Professor Spooner and Mr. Davis have applied with decided success, to the alleviation of farcy, glanders, and nasal gleet.

**Hydargyri Submuriaria**—Submuriate of Mercury—Calomel.

Take of Purified Mercury (by weight) 4 lb. Sulphuric Acid . . . . 30 oz. Muriate of Soda . . . . 1½ lb. Muriate of Ammonia . . . 8 oz.

Boil 2lb. of the mercury with the sulphuric acid in a glass vessel, until the mercury formed is dry. When this is cold, triturate it with the other 2lb. of mercury in an earthen mortar; then add the muriate of soda, and rub them together, until globules are no longer visible. Afterwards reduce the sublimed matter to a very fine powder; pass it through a sieve, and mix it very carefully with the muriate of ammonia, previously dissolved in a gallon of boiling distilled water; set it by, that the powder may subside. Pour off the solution, and wash the powder frequently with boiling distilled water, until solution of ammonia drops, and throws down precipitate; lastly, let it be reduced to a very fine powder.

**Decomposition.**—It is the same as the preceding article, with only this difference; that one-half of the chlorine unites with the fresh portion of mercury added, so that the per or bi-chloride becomes converted into chloride, or
pro-chloride of mercury. The muriate of ammonia appears to be added for the purpose of dissolving any corrosive sublimate which may be formed with the calomel.

**Medicinal Uses.**—Anthelmatic, or vermifuge and alterative; for these it is given, in doses of from one to two drachms, in the form of a ball, at night, and a dose of aloe in the morning. It is used in cases of surfeit, worms, or mange; also, sometimes, for chronic cough, farcy, and jaundice. Taken alone, it is only slightly purgative on the horse, and is given in doses of from a scruple to a drachm. In arresting the violence of epidemic catarrh, calomel has recently gained a high reputation.

**Kino—Kino.**

An extract, prepared from a non-descriptive African tree.

**Medicinal Uses.**—Astringent, given in doses of from two to four drachms, generally in combination with chalk.

**Lime.**

*Lime* is one of those earthy substances which exist in every part of the known world, and is found purest in limestone, marble, and chalk. None of these substances are lime, but are capable of becoming so by being burnt in a white heat.—It may be also obtained perfectly pure by burning calcareous spar, and also by burning some pure white marbles. It may be procured also in a state of purity by dissolving oyster-shells in muriatic acid. It has been ascertained by Sir H. Davy to consist of oxygen and a metallic basis, which he denominates calcium.

**Linum Semina—Linseed.**

The seed of the common flax, a well-known annual plant, which flowers in July; the seed ripens in September.

**Medicinal Uses.**—Demulcent, given in any quantity. Two ounces of the seed, boiled in two pints of water for a short time, will form an excellent jelly-like-fluid, for the administration of any of the sulphates. In cases of sore throat or catarrh, affections of the bowels or the urinary organs, an infusion of it is frequently given instead of water. Thin gruel, however, is to be preferred. As a poultice the meal answers almost for every purpose.

**Myrrh—Myrrh.**

*Myrrh* is a gum resin brought from the Lævant and East Indies, and used in medicine. It is hard, dry, glossy, of a reddish-brown colour, with an admixture of yellow; transparent or opaque; of a peculiarly strong smell, and a bitter, somewhat biting taste. With water it forms a yellow opaque solution, and by distillation yields an essential oil. It is imported into this country in chests.

**Medicinal Uses.**—Stimulant, applied externally, in the form of tincture. United to the tincture of aloes it may be applied to wounds as a stimulative and digestive agent. Inwardly, however, it is of little use, although, when combined with opium, it is sometimes administered in cases of chronic cough.

**Nicotiana—Tobacco.**

Of this narcotic there are several kinds. English tobacco seldom grows to more than three feet in height, having smooth alternate leaves upon short foot-stalks; flowers in small loose bunches on the top of the stalks, of a yellow colour, appearing in July; which are succeeded by roundish capsules, ripening in the autumn. Sir Walter Raleigh, on his return from America, is said to have first introduced the smoking of tobacco into England. In a house in which he lived, at Islington, his arms are said still to be seen, with a tobacco plant on the top of the shield. It is remarkable that tobacco has prevailed over the original name, petum, in all the European languages, with very little variation, and even in Tartary and Japan. Tobacco is derived from the island of Tobago. Petum is the Brazilian name.

**Medicinal Uses.**—Limited; but, in the hands of a good practitioner, may be rendered serviceable in extreme cases of costiveness, or in dangerous colic. Let it never be used internally for the promotion of a fine coat, or as an external application for mange.

**Oleum Oliva—Olive Oil.**

The olive tree is a native of the South of Europe, cultivated in great abundance in France and Spain. It seldom becomes large; but two or three stems frequently rise from the same root, from twenty to thirty feet in height, putting forth branches almost their whole
length, covered with a greyish bark. The oil is produced from the ripe fruit which is gathered in November, and immediately crushed in a mill, the stones of which are kept so wide as not to bruise the nut. The pulp is subjected to the pressing bags, made of rushes; and by means of gentle squeezing the best oil flows first. A second oil is yielded by breaking the mass, moistening it with warm water, and turning it to the press. A third, and still inferior sort, is obtained by boiling the residue, or by breaking, moistening, and fermenting it in large cisterns, and again submitting it to the full force of the press.

**Medicinal Uses.**—Aperient to an inconsiderable extent in the horse. Emollient. It may be given in the quantity of a pint. Over castor oil it possesses no advantage. It enters into the composition of liniments, &c.

**Oleum Picis Liquide.**—Oil of Tar.

Take of Tar . . . . 5 lbs.

" Water . . . . 4 pints.

Distil from a retort with great care. What remains in the retort is pitch.

**Medicinal Uses.**—Stimulant and irritant. This is only used as an external application, either alone, or combined with olive oil, as in the **Linimentum Picis Liquide.**

**Oleum Sulphuratum.**—Sulphurated Oil.

Take of Washed Sulphur . . . . 2 oz.

" Olive Oil . . . . 1 pint.

Heat the oil in a very large iron vessel, and add the sulphur by degrees to it; and keep constantly stirring them with a spatula, till they are combined. This is merely a solution of sulphur and oil.

**Medicinal Uses.**—Used, in the language of the laboratory, to kill the quicksilver in making the **Unguentum Hydrargyri Fortius.**

**Oleum Terbinthina.**—Oil of Turpentine.

Take of Common Turpentine . . . . 5 lbs.

" Water . . . . 4 oz.

Distil the oil from a copper alembic with great care. What remains in the retort is resin.

**Medicinal Uses.**—Diuretic; stimulant; given in doses of from two drachms to one ounce; this acts as a diuretic; but in doses of from four ounces to eight, it acts as a stimulant to the intestines in cases of gripes. Applied to the skin, it is a violent irritant; but combined with olive oil, it forms a useful embrocation.

**Opium.**

The white poppy, of which this is the produce, is a native of Asia; but is sometimes found growing wild in England. The market is principally supplied with opium from Turkey, though the poppy is cultivated in almost all states in Europe. To obtain opium, the half-ripe capsules have all, after sunset, longitudinal excisions made in them. The night dews favour the exudation of the juice, which is collected, in the morning, by means of a small iron scoop. It is then deposited in an earthen pot, where the whole is worked by the hand, in the sunshine, until it has acquired a considerable degree of spissitude. It is then formed into cakes, which are laid in basins to be further dried. Then they are covered with tobacco, or poppy leaves, and packed in chests, in which state they are imported to this country.

**Medicinal Uses.**—Producing but little effect on the horse; none as a narcotic; like the narcotic used by the human subject, generally acting as an irritant. It is, however, a powerful astringent, sedative, and anti-spasmodic. In the treatment of tetanus, or locked-jaw, it is greatly relied on in veterinary practice. It should, however, at all times, be administered with caution. In cases of ophthalmia it is useful, applied externally. It, in instances where the cantharides, or blue vitriol, have been used to too great an extent, there is no drug equal to opium for quieting the disorder they may have occasioned. It is administered in the form of a ball, in doses of one or two drachms, according to circumstances; other medicines are generally combined with it.

**Petroleum.**—Barbadoes Tar.

This variety of bitumen is collected from the surface of water, which exudes from the sides of hills, in which pits are sunk for its reception, and skimmed every week. It is the same as naphtha—now a well-known liquid in this country.

**Medicinal Uses.**—Stimulant. It is applied externally, but possesses no advantage over common tar.
Pix Nigra—Black Pitch.

This is the residue in the retort after the distillation of the oil from tar.

Medicinal Uses.—Slightly stimulant, and adhesive; but seldom used.

Pix Liquida—Tar.

This is obtained by placing billets of the Scotch fir in large stacks, which are closely covered with turf; and to which fire is then applied. They are suffered to burn with a slow, smothered flame; during which time tar is formed by the decomposition of the resinous juice of the wood, which flows to the bottom, and runs out at a small channel cut for the purpose.

Medicinal Uses.—Stimulant applied externally, entering into the composition of Unguentum Picis Liquida. Melted with an equal quantity of grease it makes the common stopping of the farrier, and is extremely useful for dressing bruised or wounded feet. Its chief value, however, in veterinary practice does not arise from its keeping out dirt and water from the wounded part, but from its mollifying influences on the horse itself, making the part more elastic, yet softer, and less likely to break away. It is the proper basis of thrush ointment, and is also used as an ingredient in the applications for mange. The spirit of tar, combined with double the quantity of fish oil, is one of the very best applications that can be made to hard and brittle feet. Tar is sometimes given in doses of two or three drachmas, in cases of chronic cough.

Plumbi Oxydum Semivitium—Semivitrified Oxide of Lead—Litharge.

Lead is a white metal of a considerably blue tinge; very soft and flexible; not very tenacious. Its sp. gr. is 11.35. It melts at 612 deg.

This oxide of lead is prepared by the action of heat and air upon the metal. The lead is placed upon a warm furnace in a hollow dish made of ashes, and kept at a red heat with the blast of a large pair of bellows directed on its surface. An oxide soon appears, and is successively formed by raking it, and exposing it to a new surface.

All the oxides of lead are easily revived with heat and carbon. Oxygen and lead combine together in different proportions. If the nitrate of lead be dissolved in a precipitation produced by potash, the precipitate, when dried, will become the yellow protoxide. If it be somewhat vitrified, it constitutes litharge; and combined with carbonic acid, it becomes white lead, or ceruse. Lead, alloyed with an equal weight of tin, ceases to be acted upon by vinegar. Acetate and sub-acetate of lead have a good effect, as external applications, for inflamed surfaces, burns, scrofulous sores, and as eye-washes. Lead, taken internally, is very injurious; hence the diseases to which painters are liable. Litharge, dissolved in wines, to give them a sweet taste, is very mischievous. Sulphured hydrogen will cause it to throw down a black precipitate.

Medicinal Uses.—In making the liquor plumbi superacetatis. For the deleterious effects produced upon animals in the neighbourhood of lead works, active purgatives, followed by opium, are the most effective remedies.

Plumbi Superacetatis—Superacetate of Lead.

Take of Carbonate of Lead . 1 lb.
" Acetic Acid . . . 1½ gallon.

Boil the carbonate of lead with the acid until it is saturated, then filter it through paper, and evaporate it until a pellicle appears. Set it aside to crystallise from off the super natant born fluid, and dry the crystals on blotting-paper.

Medicinal Uses.—Cooling, applied externally in the form of solution, for inflammation of the eyes. Goulard’s ointment, however, is a better preparation for external and superficial inflammation.

Potassae Nitrates—Nitrate of Potash—Nitre.

Nitre is the common name of the nitrate of potash. It is known by the name of saltpetre, and is found ready formed in the East Indies, in Spain, in the kingdom of Naples, and elsewhere, in considerable quantities; but nitrate of lime is still more abundant. For the greater part of the nitrate made use of, is produced by a combination of circumstances which tend to compose and condense nitric acid. This acid appears to be produced in all situations where animal matters are completely decomposed through the action of air upon
RESINA FLAVA—Yellow Resin.

The residue in the retort, after the distillation of the oil from the common turpentine; but should the process, from the distillation of the turpentine, be carried on without water, what remains in the retort will be amber-coloured resin; but this is easily made yellow by adding, while it is fluid, a small quantity of water, shaken together.

Medicinal Uses.—Diuretic, in doses of from four to eight drachms, combined with soap, in the form of a ball, making the bolus according to the directions of the college.

SAPO CASTIL—Castile Soap.

This soap is prepared in Spain, and takes its name from a city in that country. It is formed by the combination of barilla with olive oil; to which is added a small quantity of sulphate of iron, which gives it its marble appearance.

Medicinal Uses.—Slightly diuretic; rarely given alone; chiefly in union with resin.

SAPO MOLLIS—Soft Soap.

This is made in the same way as the above, with the exception, that potash is used instead of barilla or soda, and the colouring matter left out.

Medicinal Uses.—As the former; in case of gripes caused by the exhibition of sulphate of copper, from two to four ounces, dissolved in water, have been given with great success.

SODII CHLORIDUM—Common Salt.

The preparation of that kind of salt which is used for culinary and economical purposes (muriate of soda), depends upon the well-known fact, that the salt contained in the sea-water, or brine springs, being a fixed body, will not rise with the vapour of the water. All, therefore, that is wanted, is to expose any water, containing salt, to evaporation. The veterinarian employs common salt largely; and when sprinkled over hay, or in a mash, is liked by sick horses, to which it sometimes proves eminently beneficial.

Medicinal Uses.—Aperient; a solution of half a drachm of salt in four ounces of water, forms an excellent lotion for inflamed eyes.
**Sinapis—Mustard.**

A genus of plants belonging to the class of *tetradynamia*, and to the order of *siliquosa*; and in the natural system it is ranged under the 39th order, *siliquosa*.

**Medicinal Uses.**—This has been applied to the throat, chest, and bowels, in cases of inflammation. It is done by rubbing, which, exciting an outward irritation, allays the inflammation within.

**Spiritus Rectificatus—Rectified Spirits of Wine.**

This may be obtained by distillation from any vegetable substance, in which the vinous fermentation is not completely over; the first result is ardent spirits, as brandy, rum, &c. It is from redistillation that rectified spirits are produced, which is very simple, being nothing more than the repetition of the process of distillation, with the addition, if necessary, of some alkali or lime, to destroy the empyreumatic flavour, and absorb the water. Proof spirits is made by mixing nearly equal parts of water and rectified spirits.

**Medicinal Uses.**—Stimulant; principally used as a menstruum.

**Sulphur Sublimatum—Sublimed Sulphur.**

*Sulphur* is a well-known substance, sold in the form of a powder, or in solid pieces, when it is called brimstone. It is found in the neighbourhood of volcanoes; in the tract of land between Naples and the ancient Baiae, called Solfà-terra, the smoking plains, the remnant of a half-extinguished volcano, it is found in great abundance. It is brought in large quantities to this country from Mount Etna, in Sicily; but is to be obtained in greater or smaller quantities near all volcanoes, of which the number throughout the world is considerable. It is also often found in coal mines; and, indeed, the common coal in our fires more or less contains this mineral. It often appears combined with iron, copper, and other metals, when it is called pyrites.

**Medicinal Uses.**—As a drug it forms the basis of the most effectual application for mange. When combined with nitre and antimonary, it is an excellent alternative in cases of surfeit, grease, hide-bound, mange, or out of condition. In a cough or fever it is likewise a useful ingredient. As an opening medicine, it is not so good as many other aperients.

**Terebinthine Vulgaris—Common Turpentine.**

This is procured from Scotch fir, when the tree is about forty years old, by stripping off the outer bark to the extent of six inches, so as to expose the inner smooth bark, near the foot of the tree, making a wound with an instrument three inches square, and one inch deep. From this incision the resinous juice soon begins to exude in transparent drops, which fall into a hole previously dug to receive them. Fresh incisions are continued to be made till the month of September. A healthy tree will yield from eleven to twelve pounds of turpentine annually, for a century. It is afterwards purified by filtration, through casks with holes in the bottom.

**Medicinal Uses.**—Diuretic; externally digestive; as a diuretic, given in doses of from one drachm to eight drachms, in form of a ball; as a digestive externally, it is used in the form of unguentum. *The oil of turpentine*, as an antispasmodic, for the removal of colic, has no equal. With cantharides, used as a blister, it is far inferior to the common ointment.

**Terebinthine Veneta—Venice Turpentine.**

This is the product of the larch fir, obtained in a similar manner to the foregoing; but the largest quantity of the Venice turpentine is made by melting together the amber-coloured resin and oil of turpentine.

**Medicinal Uses.**—Similar to the foregoing, to which it gives place, possessing no advantage over it.

**Veratrum Radix—White Hellebore Root.**

This plant is a native of the mountainous parts of Greece, Italy, Switzerland, Russia, &c. The root is dug in autumn, and dried.

**Cerum—Wax.**

The upper surface of the leaves of many trees is covered with a varnish, which may be separated and obtained in a state of purity, and which is found to possess all the properties of beeswax; hence it is justly inferred that wax is a vegetable product, and that the bees ex-
tract it unaltered from the leaves of trees, and other vegetable substances that contain it. Several plants contain wax, in such abundance as to make it worth while to extract it from them.

Medicinal Uses.—In ointments, and some plasters, the yellow soap is used to make them less brittle. In small doses (and with great attention), from one scrupul to one drachm, frequently giving it, will produce a sedative effect; but if this effect be not narrowly watched, or if the dose be increased from one drachm, nausea will be produced, and violent irritation. As it is a powerful diuretic cathartic, it must be used with extreme caution. Externally it is combined with oil. It may, however, be used with advantage in affections of the skin, either in the form of decoction or ointment. We must repeat that, without the utmost care, it is a dangerous drug.

The Black Hellebore is used mostly as an external application, and has a strong, stimulating power. It has been resorted to with success in fistulous affections of the poll and withers. Professor Morton observes, "that an ointment, formed of either the white or black hellebore, in the proportion of one part of the powder to eight parts of larch, will be found exceedingly active for the dressing of rowels and setons."

Zinc Oxidum.—Oxide of Zinc.

In chemistry and mineralogy, zinc was a metal unknown to the ancients, though they were acquainted with calamine, one of its ores, and the effect which this had in converting copper into brass. It is of a white colour, with a shade of blue; in a fresh fracture it is possessed of considerable lustre. It is hard, and not easily cut with a knife. The specific gravity is nearly 7:2. Its ores are calamine and blende.—Calamine is an oxide, frequently with a portion of carbonic acid; blende is a sulphuret, containing also some iron, and other extraneous matters.

Zinc is melted by a moderate heat; and the fused mass, on cooling, forms regular crystals. Though scarcely altered by exposure to the air at a low temperature, yet it is rapidly oxidised by one amounting to ignition. When kept in a degree of heat barely sufficient for its fusion, it becomes covered with a grey oxide. But when thrown into a crucible, or deep earthen pot, heated to whiteness, it suddenly inflames, burns with a beautiful white flame, and a white and light oxide sublimes, having a considerable resemblance to carded wool.

Medicinal Uses.—Tonic; but in the impure state, under the name of Calamine Powder, used as an ointment, known as "Turner's Cerate," it is invaluable. This ointment has been distinguished as "The Healing Ointment," and is composed of five parts of lard and one of resin, melted together. When these begin to cool, two parts of the calamine, reduced to an impalpable powder, are stirred in. On cracked heels, and superficial sores, calamine is sometimes advantageously sprinkled.

Zinci Sulphas.—Sulphate of Zinc—White Vitriol.

Take of Zinc, in small pieces . . . . 4 oz.

" Sulphuric Acid (by weight) 6 . . .

" Distilled Water . . . . . . . . . . 4 pints.

Mix them in a glass vessel; and the effervescence having ceased, filter the solution through paper, then boil it till a pellicle appears. Set it by, that crystals may form.

Decomposition.—The same process acts here as in the preparations of the sulphate of iron and copper. The oxygen of the water unites to the zinc, converting it into an oxide of zinc, which is dissolved by the sulphuric acid forming sulphate of zinc; whilst the hydrogen of the water assumes the elastic form, and escapes.

Medicinal Uses.—Tonic internally; stimulant externally. As a tonic, it is given in doses from one drachm to half-an-ounce; but it is now rarely used at the College. It is used externally to promote healthy granulations; and may be applied either in the form of solution or ointment.

Zingiberis Radix.—Ginger Root.

This plant is a native of the East Indies, but is now cultivated in the West Indies, to very great advantage. Our finest quality comes from Jamaica. The root is dug up after the herbaceous part of the plant is withered in January, and dried in the sun. There are many sorts in the market, but they all possess similar properties, differing slightly in strength.
Medicinal Uses.—Carminative, in doses from half-an-ounce to two ounces; in the form of ball it is the active ingredient in the formula, bolus cardææa. As a stimulant it is good.

List of Medicines referred to in the first division of this Work.—In all the following compounds, No. I. must be regarded as exhibiting the mildest form; No. II. as the next stronger; No. III. as still stronger; and so on, rising in degrees of strength, according to the numerals by which they are indicated.

In concluding this portion of our subject, we must observe, that the less a person has to do with medicine, whether for himself or his horse, the better; but there are occasions when it will assist nature, alleviate pain, and clear the way for a more speedy cure than might be expected if nature were left entirely to her own operations. Physicking horses is very common when they are taken up from grass, and its administration is, generally, admitted to be beneficial when they feed badly, and appear heavy, and especially if the eyes and mouth are of a yellowish colour. Proper attention to the airing of the stable, to its perfect cleanliness, and to feeding, exercise, and training, is the great duty to be attended to by those to whom the management of horses is assigned. Open air exercise is, above all things, essential to the well-being of every animal endued with the powers of locomotion. To the horse it is especially necessary; for, if kept in a stable without it, his degeneration becomes extremely rapid. This is soon evidenced by the decline of muscular power, and by the generation of disease in both the digestive and respiratory organs; by the growth of the hoof; the elongation of the toe; the inflammation of the frog; and, in short, by the whole body becoming diseased. Exercise is, therefore, not only essential to his health, but to his very existence. Let this, then, be regularly attended to, in conjunction with cleanliness and a proper regimen; and it will be found that medicine will not be required very often by the noblest conquest which man has made over the brute creation.
DIVISION II.

THE DOG AND ITS VARIETIES.

CHAPTER I.

ORIGIN OF THE DOG.

With something like a feeling of hesitation we enter on the history of the dog, respecting whose origin there are few naturalists agreeing with one another, and most of them suggesting different theories, having their rise in the reasoning of conjecture or probability, and little to support them beyond the speculations of ingenuity. To no animal is mankind so largely indebted for affection, attachment, and obedience, as to this. Among all the various orders of the brute creation, none has hitherto been found to identify itself so closely with the interests of his master; none has been found so admirably subdued to his purposes; and none so well adapted to watch or protect himself or his property in the hour of danger, darkness, or destruction. In both the old and the new worlds, there are many countries in which, if he were deprived of this faithful companion and ally, he would resist his enemies without success. His person would be insecure; his labour would frequently be vain; and his property would become a prey to the ravages of other animals stronger and swifter than himself. Whatever may be the amount of vigilance with which the Supreme Being has gifted him, there are many situations in which he could not be secure from rapacity on the one hand, or speed on the other; but in the dog he possesses the most faithful of friends; the most constant, whether in adversity or prosperity, and the only one that voluntarily lays all his extraordinary qualities at his feet; resigns himself up to his direction; obeys his voice under all circumstances; conforms himself to his movements, and identifies his own with the habits of his master.

"It proclaims
Th' audacious felon; foot by foot he marks
His winding way—while all the list'ning crowd
Applaud his reasonings—o'er the watery ford,
Dry sandy heaths, and stony barren hills;
O'er beaten paths, with men and beasts disdain'd,
Unerring he pursues; till at the cot
Arrived, and seizing by his guilty throat
The caitiff vile, redeems the captive prey;
So exquisitely delicate his sense!"

In the battle he is fierce; in the chase he is persevering; in the house he is watchful; and his patience is inexhaustible. In disposition he is so friendly that he seems only to remember the benefits he receives. Blows he soon forgets; and, generally speaking, in place of discovering resentment when he receives them, he licks the hand by which they were administered. It is no wonder that such an animal has, from remotest antiquity, attracted the notice, and received the countenance and favour of man, whether enrobed in the splendour of regal purple, or invested in the meanest and most fragmentary garments imaginable!

It was the opinion of Pallas that the dog is a factitious animal, not descended from any single original wild stock, but from a mixture of nearly allied primitive species, whose hybrid offsprings have possessed prolific powers; and he observes, that those domesticated animals,
THE WOLF.]  

THE DOG, AND ITS VARIETIES;  

who was deceived by the ferocious wolf. Ly-  

canthropos of the Greeks, the Were-wolf of the  
Anglo-Saxons, and the Loup-garon of the  

French, had reference to some such preter-  
natural monster, whose name was associated  
with all that is horrible and mysterious. Con-  
spicuous then, and dreaded for its power and  
rapacity, it can scarcely be wondered that the  

wolf should have had its name assumed, or  
given to men of distinction, by our barbarous  

but warlike forefathers, among whom such ap-

pellations as Ethelwolf, Eadwolf, Berthwolf,  

and many more, were common.

Our Saxon ancestors, however, did not suffer  

the wolf to ravage the country unmolested.  

In the tenth century, under the reign of  

Edgar, the work of exterminating this animal  

began, and appears to have been carried on  

with success down to the thirteenth century;  

when, during the reign of Edward I., all his-

torical record, by way of royal edict, ceases in  

reference to continuing the work of wolfine  

extermination. The last record of their existence in any  

formidable numbers was in 1281. It is said  

by Mr. Topham, in his notes to Somerville's  

Chase, that it was in the woods of Yorkshire  

where a price was last set upon a wolf's head.  

In Scotland and Ireland the wolf remained for  
a considerable period longer. In 1577, accord-

ing to Hollinshed, wolves were destructive to  

the flocks in Scotland; and in Ireland they were  
exterminated only at the beginning of the last  

century.

From the numerous allusions to the wolf in  
the Scriptures, it is evident that it must have  
been well-known formerly in Syria—and indeed  
also in Egypt, for we find it figured on  
ancient sculptures, together with the hyæna  
and greyhound. At present, however, this  
animal is seldom met with in Syria, although  
it still exists in that region, but keeps itself  
concealed.

So habitually cautious and suspicious is the  

wolf, that it is difficult to take it in traps; and  

for the same reason, anything like the appear-

ance of artifice, deters it from an attack. It  
has been supposed that it never carries its  
tail raised. This, however, is not altogether  
correct. A visit to the Zoological Gardens,  
in the Regent's Park, London, will enable the  
curious upon this point to satisfy themselves  
that wolves do elevate their tails whilst gallop-
ing round the area in which they are enclosed. Dr. Richardson states from observation, when they gambol with each other, they elevate their tails.

When pursued, the wolf rushes along, with his muzzle almost to the ground, his eyes glowing like fire, the hair of his neck and shoulders erect, and his tail lowered and drawn close; when out of danger, he slackens his pace, raises his head, sniffs about, and whirls his tail around, as if exulting in his escape; but if brought to bay by hounds, he defends himself to the last, and often kills and maims some of his antagonists before he falls overpowered by numbers. In hunting him, the Kirghese Tartars employ a large hawk, which fastens upon the animal's head, and tears out its eyes.

The power of the wolf, especially in the muscles of the head, neck, and shoulders, is immense; and his bite is terribly severe, generally cutting out the flesh with a snap. Among themselves they fight often with great desperation, the combat ending with the death of the weaker. It is said that wolves wounded by the gunshot of hunters or travellers, are torn in pieces and devoured by their fellows. This is not characteristic of the dog.

The average height of the animal at the shoulders is about two feet six inches. The female rears her young in some cave or gloomy recess, and produces from five to nine young at a birth. These are born with the eyes closed, as in the dog. In the defence of her offspring the female is furious, and greatly to be dreaded. The voice of the wolf is a prolonged howl, resounding dismally through the stifly darkness of the night. Not so the dog's.

On the southern side of the Pyrenees there exists a variety, perhaps, of the wolf, termed, from its colour, the Black Wolf—the Loup noir of Buffon. This animal is asserted to be more ferocious than the ordinary grey wolf; but, perhaps, without any foundation.

Desmarest says that the wolf is solitary and nocturnal; but that in winter it unites in troops, which attack horses and men. The sense of smell is very acute; but its speed is not very great, and it wearsies out its victim by dint of untiring perseverance. When in full chase of its prey, it gallops along, pertinaciously following the track of the fugitive.

Lord Byron, in his poem of Mazeppa, vividly depicts the scene of a troop of wolves in pursuit of their prey:

"We rustled through the leaves like wind,
Left shrubs, and trees, and wolves behind;
By night I heard them on the track,
Their troop came hard upon our back,
With their long gallop, which can tire
The hound's deep hale and hunter's fire;
Where'er we slew they followed on,
Nor left us with the morning sun.
Behind I saw them scarce a road
At daybreak winding through the wood;
And through the night had heard their feet
Their stealing rustling step repeat."

In almost every department of France infested by the wolf, there is a society called Société de Louveterie, the object of which is to keep that animal down; and premiums, varying in amount according to the sex and age of the animals killed, are likewise paid. The means hitherto employed, however, have been inadequate to effect the purpose. Although we can adduce several instances of the ferocity of certain species of dogs, there is nothing of which we are aware on record, which indicates a disposition at all approaching the unrelenting native ferocity of the wolf.

In the province of Posen, Prussia, in 1814, three grown persons and sixteen children were devoured by wolves in the small circle of Wongrowiece alone. When Prussia regained the province of Posen, in 1815, no time was lost by the government in getting rid of so great a public nuisance; and in that province, within five years, from 1815 to 1819 inclusive, 4,018 dollars were paid by the government in rewards for killing wolves.

In the parish of Brial, district of Rawat, during the month of August, 1837, four girls were torn to pieces not far from their own houses. This was in summer.

Mr. Lloyd, in his Field Sports in the North of Europe, relates many events respecting these animals. It would appear that they are less dangerous to man than might be expected, though they sometimes, especially when combined in troops, attack travellers with great audacity. A gentleman attached to the embassy of St. Petersburgh, narrated to him the following circumstance:—"It happened at no great distance from St. Petersburgh,
and only two years previously, that a peasant, one day in his sledge, was pursued by eleven of these ferocious animals. At this time he was only about two miles from home, towards which he urged his horse at the very top of his speed. At the entrance of his residence was a gate, which happened to be closed at the time; but the horse dashed this open, and thus himself and his master found refuge in the court-yard. They were followed however, by nine out of the eleven wolves; but very fortunately, at the very instant these had entered the enclosure, the gate swung back on its hinges, and thus they were caught as in a trap. From being the most ferocious animals, the nature of these beasts, now that they found escape impossible, became completely changed: so far, indeed, from offering molestation to any one, they slunk into holes and corners, and allowed themselves to be slaughtered almost without making resistance." There is not a single characteristic of the dog in this anecdote. Supposing that eleven dogs, hounds, mastiffs, bulls, or terriers, had pursued a man into his yard, and found themselves thus suddenly enclosed, would they have slunk into holes and corners, and exhibited such symptoms of fear and cowardice? On the contrary, we think that every one of them would have been more ardent than another in seizing their prey, and making a victim of the man who had given them such a run. Further on we shall give an instance of a pack of native wild dogs of India pursuing Colonel Sykes; but exhibiting no such traits of fear, although deterred from an actual attack by the report of fire-arms. The cowardice of the wolf presents, in our opinion, a perfect contrast to the courage of the dog.

It is said, that the mere act of striking a light with flint and steel has often the effect of intimidating a wolf; and that the rattling of a chain not infrequently answers the like purpose. In the event of a person, when unarmed, being attacked by these bloodthirsty brutes, these things are worth knowing; for, although apparently trifling in themselves, they might be the means of saving his life.

In some parts of Scandanavia, when people are travelling, during the winter-time, over extended plains, lakes, &c., which are known to be much frequented by wolves, it is the custom to attach a long rope to the back of the sledge. The serpentine motion that this makes when the vehicle is proceeding, has, it is said, the effect of deterring these animals from making their attacks.

The common wolf of North America differs in some respects from its European relative, and is perhaps a distinct species. It wants the gaunt appearance, the comparatively long jaw and tapering nose, the high ears, long legs, slender loins, and narrow feet of the European wolf. Its frame also is more compact, the fur finer and thicker, the muzzle more obtuse, the head larger and rounder, and the forehead broader and more arched. The limbs are shorter, and the tail more fox-like and bushy.

Dr. Richardson, in his 

Fauna Boreali-Americana,

enumerates several varieties of this North American wolf, depending on colour—viz., the grey, the white, the pied, the dusky or clouded, and the black. Black wolves abound on the Missouri; and, according to the Indians, black and grey wolves occur in the same litter. The dusky, or clouded wolf, was regarded by Say as a distinct species, and named by him Canis nubilus.

The American wolf agrees in its general habits with the wolf of the European continent, though it appears to be less formidable as far as man is concerned. Indeed, Captain Lyons, in his observations on the wolves of Melville Peninsula, states that both English and Esquimaux were accustomed to pass them without any weapon, or even a stick; "the animals, however, exhibited no symptoms of fear, but rather a kind of tacit agreement not to be the beginners of a quarrel, even though they might have been certain of proving victorious."

These wolves hunt in packs, and when pressed for food, assume an astonishing degree of boldness. They will seize the Esquimaux dogs before their masters' faces, and carry them off—although this species of dog is brave in attacking the bear, but is terrified at the wolf. They have been known not only to steal provisions from under a man's head in the night, but even to enter the bivouac of a traveller, and carry off some of his dogs. "During our residence at Cumberland House, in 1820," says Dr. Richardson, "a wolf which had been prowling round the
fort, and was wounded by a musket-ball and driven off; returned after it became dark, whilst the blood was still flowing from its wound, and carried off a dog from amongst fifty others, that howled piteously, but had not courage to unite in an attack on their enemy."

The American wolf is extremely cunning, and, in attacking moose, or Wapiti deer, animals which exceed it in speed, it has recourse to a singular stratagem. Several combine, and arrange themselves in the form of a semi-circle, and thus advance upon their prey, so as either to hem it in or drive it over a precipice. Captain Franklin often found the remains of deer which had been thus dashed down steep cliffs and devoured; and he states that this is a frequent expedient when the plains are bounded by precipitous cliffs. "Whilst the deer are quietly grazing, the wolves assemble in great numbers, and, forming a crescent, creep slowly towards the herd, so as not to alarm them much at first; but when they perceive that they have fairly hemmed in the unsuspecting creatures, and cut off their retreat across the plain, they move more quickly, and with hideous yells terrify their prey, and urge them to flight by the only open way, which is towards the precipice, appearing to know that when the herd is once at full speed, it is easily driven over the cliff; the rearmost urging on those that are before. The wolves then descend at leisure, and feed on the mangled carcasses."

On one occasion a troop of wolves endeavoured to put the same stratagem into practice against Dr. Richardson. Having the first watch, he "had gone to the summit of a hill, and remained seated, contemplating the river that washed the precipice under his feet, long after dusk had hid distant objects from his view. His thoughts were, perhaps, far distant from the surrounding scenery, when he was roused by an indistinct noise behind him; and, on looking round, perceived that nine white wolves had ranged themselves in form of a crescent, and were advancing apparently with the intention of driving him into the river. On his rising up they halted; and when he advanced, they made way for his passage down to the tents." This may be taken as an indication of that kind of instinctive intelligence which all wild animals, more or less, possess when actuated to preserve themselves from danger, or to hunt for their prey. In the wolf, it is, perhaps, somewhat remarkable.

Very different from the above respectful conduct which these wolves showed to Dr. Richardson, was that which a pack of them displayed to a poor Scandinavian soldier.

Whilst this unfortunate man was crossing a large lake, called Stor-sjon, it then being the depth of winter, he was attacked by a drove of wolves. He was armed only with a sword; but with this weapon he defended himself so gallantly, that he not only killed or wounded several of his assailants, but he succeeded in driving off the remainder.

Some short time afterwards, however, the same drove of wolves again beset him. He was now unable to extricate himself from his perilous situation in the same manner as before; for, when he laid his hand upon his sabre, and attempted to draw it, he found it firmly frozen into the scabbard. This was in consequence of his having neglected to wipe the blood from the blade after the desperate conflict in which he had been engaged. It is almost needless to add, that as he was then defenceless, the ferocious beasts quickly killed and devoured him.

In the dreary realms that advance into the Polar Sea—

"Where the wolf and Arctic fox
Prowl amidst the lonely rocks"—

Captain Franklin and his companions, during their arduous journeys, were often obliged to dispute their scanty food with the lean wolves, that would scarcely retreat. On one occasion, when they had captured a moose, and had buried a part of the body, the wolves absolutely dug it out from their very feet, and devoured it while the weary men were sleeping. On another occasion, when the travellers had killed a deer, they saw, by the flashes of the Aurora borealis, eight wolves, waiting round for their share of the prey. Sometimes, however, the wolves were their caterers, and helped them to a welcome meal. When a group of wolves and a flight of crows were discovered, the travellers knew there was a carcass to be divided, and they sometimes succeeded in obtaining a share of the prey, if it had been recently slaughtered.

Of the American wolves, we may notice the
Prairie wolf, the Canis latrans of Say, which inhabits the plains of the Missouri and Saskatchewan, as well as those of the Columbia. It is smaller and fleeter than the common wolf; associates in large troops, and dwells in burrows on the plains, remote from the forests. In Mexico is found a distinct species of wolf, the Canis Mexicanus of Desmarest; and a species termed the red wolf, inhabits the Pampas of La Plata. The Antarctic wolf is a native of the Falkland Isles, and seems to be an intermediate link between the wolves and foxes. It feeds principally upon a species of goose (Anser leucopterus); goes in packs, which wander about by day, but more commonly in the evening, and burrow in holes. This species is about fifteen inches in height at the shoulder; the tail is short, and white at the tip; the limbs are short, but the contour of the head is wolf-like. It is termed by Penault the Antarctic fox.

Colonel Sykes has described a wolf from Dukhun, under the title of Canis pallipes, which he states to be numerous in the open, stony plains of that region, but not to be met with in the woods of the Ghauts.

Mr. Hodgson notices the common European wolf as occurring in the lower region of the Nepaul Mountains.

Wolves are said to be particularly partial to dogs. This is noticed by Mr. Lloyd, in his Field Sports in the North of Europe, where he says, those animals usually picked up every one that was at large in this part of the country. Several were taken from both Risater and Uddeholm. Careesse was the drawing-room pet at the latter mansion, and was as fat and as sleek as a mole; but, happening to be star-gazing one evening, just outside the door, a famished wolf whipped her up in his horrid jaws, and was instantly across the lake with her.

The same writer gives us another instance of the audacity of these animals. "It was Christmas time, and there were fifteen or sixteen sledge in company; most of the horses were provided with such bells as are used in Scandinavia. In the middle of the cavalcade was a sledge occupied by a lady; at the back of the vehicle, as is frequently the case, sat the servant, who was driving; whilst on a bearskin, which covered her feet, a favourite lap-
dog was reposing. In passing through a wood, however, and in spite of the jingling of the bells, &c., a large wolf suddenly sprang from a thicket, when, seizing the poor dog, he leaped over the sledge, and was out of sight in a thick brake on the opposite side of the wood, in the course of a few seconds."

Fierce as the wolf is, however, it can be tamed, and even domesticated; but it requires to be taken very young; and this is, perhaps, one of the characteristics that brings this fierce, yet cowardly animal into relationship with the dog. M. F. Cuvier gives a very interesting account of a tame wolf, which showed all the affection that the most gentle dog could evince towards its master. When full-grown, he was presented by his owner to the menagerie at Paris. For many weeks he was quite disconsolate at the separation from his master, who had been obliged to travel; he would scarcely take any food, and was indifferent to his keepers. At length he became attached to those about him, and he seemed to have forgotten his old affections. His master returned after an absence of eighteen months; the wolf heard his voice amidst the crowd in the gardens of the menagerie, and, being set at liberty, displayed the most violent joy. Again was he separated from his friend; and again was his grief as extreme as on the first occasion. After three years' absence, his master once more returned. It was evening, and the wolf's den was shut up from any external observation; yet the instant the man's voice was heard, the faithful animal set up the most anxious cries; and the door of his cage being open, he rushed towards his friend, leaped upon his shoulders, licked his face, and threatened to bite his keepers when they attempted to separate them. When the man left him, he fell sick, and refused all food; and from the time of his recovery, which was long very doubtful, it was always dangerous for a stranger to approach him. He appeared as if he scorned any new friendships.

In this anecdote we have certainly evinced a strong resemblance to a similar sensibility in the dog; and it forcibly recalls the animal of Ulysses, so much celebrated in the Odyssey, for its memory, attachment, and faithfulness. The passage is well known, having been often quoted.
Near to the gates, conferring as they drew,
Aros, the dog, his ancient master knew!
And not unconscious of the voice and tread,
Lifts to the sound his ears, and rears his head.
He knew his lord—he knew, and strove to meet;
He strives in vain to crawl and kiss his feet;
Yet, all he could, his tail, his ears, his eyes,
Salute his master, and confess his joys.

The dog, whom fate thus granted to behold
His lord, when twenty tedious years had roll'd,
Takes a last look, and having seen him, dies—
So clo'd, for ever, faithful Aros' eyes."

Other instances of wolf-domestication are on record; and they are taught, in the East, to go through certain performances in which we have seen dogs engaged in this country. This is more particularly the case in Persia, where, it is said, they are exhibited as spectacles to the people. There, when young, they are taught to dance. Buffon brought up several wolves. During their first year, he tells us, they were very docile, and even caressing; and, when well fed, would never disturb the poultry nor the other animals; but at the age of eighteen months or two years, their natural ferocity made its appearance, and they had to be chained up. One of them, up to its eighteenth or nineteenth month, lived peaceably and amicably with all things; but when he arrived at this age he made an attack upon the fowls, and killed the whole in one night, without eating one of them. This was evidently not the instigation of hunger, but of a wanton natural ferocity. Another, after breaking his chain, and killing a dog with which he lived in great familiarity, made his escape.

Before entering upon the theories which assign the wolf as the original of the dog, we will briefly describe the characteristics of the jackal, which has, also, had its advocates as being the original type of the dog. Of the animals known by this name, one species—Canis Anthus—is a native of Senegal; another, the Cape jackal—Canis mesomelas—is a native of the Cape of Good Hope; and a third, the common jackal—Canis aureus—is spread from the north of Africa, through Syria, Persia, and the greater part of India. Colonel Sykes states it to be numerous in Dukhun, where it is called Koholah by the Maharratas. It is somewhat larger than a fox, but its tail is shorter in proportion, reaching only to the hock; its head is short, with a pointed muzzle; the general colour above is grey, abruptly divided from a paler tint spread over the under surface, and the tail is slightly tipped with black.

It is supposed to be the Shimal of the Scriptures; is the Chical of the Turks; and is the Seiagal, Seitingal, Schiachal, or Shical of the Persians.

The jackal goes in troops, which lie concealed in holes and burrows during the day, but come forth at night to hunt for food. They give chase to sheep or antelopes and other animals; like the wolf, stealing, fox-like, into fowl-roosts, and attacking any living thing they are capable of overcoming. They do not, however, confine themselves to living prey. Carrion, and offal, of every description, is acceptable to them, and they devour it with the utmost greediness. Nor are roots and fruits less sought after; in the vineyard they make great havoc, and their fondness for grapes is notorious. The "shriek" of the jackal is terrific. Those travellers who have heard them, describe the nocturnal yells of these animals as extremely piercing and dissonant; now close, now at a distance—troop answering troop from different points—themselves unseen; while their fearful chorus breaks the stillness of the hours of darkness. Their cries thus heard amidst the ruins of cities of ancient date, might seem "to listening Fancy's ear" like the wail of legions of spirits over the departed glories of other days. Mouldering ruins, fallen temples, crumbling tombs, and craggy rocks, are the abodes of the jackal.

Sly and suspicious in its disposition, the jackal, when taken young, is nevertheless easily tamed, and loses that unpleasant odour which renders the wild animal almost intolerable. There is, we believe, in the Zoological Gardens, a hybrid, between the jackal and the dog.

Having thus described and illustrated, by anecdote, the disposition of the wolf, and described the characteristics of the jackal, we are sufficiently prepared to show the arguments assigned by various naturalists for the different theories they have advanced in reference to the original type of the dog. Mr. Bell is one of the most eminent defenders of the wolf theory.

"In order," says he, "to come to any rational conclusion on this head, it will be necessary to ascertain to what type the animal
approaches most nearly, after having, for many successive generations, existed in a wild state, removed from the influence of domestication and of association with mankind. Now, we find that there are several different instances of dogs in such a state of wildness as to have lost that common character of domestication, variety of colour and marking. Of these, two very remarkable ones are the Dhole of India and the Dingo of Australia. There is, besides, a half-reclaimed race amongst the Indians of North America, and another also partially tamed in South America, which deserve attention; and it is found that these races, in different degrees, and in a greater degree as they are more wild, exhibit the lank and gaunt form, the lengthened limbs, the long and slender muzzle, and the great comparative strength which characterise the wolf; and that the tail of the Australian dog, which may be considered as the most remote from a state of domestication, assumes the slightly bushy form of that animal. We have here, then, a considerable approximation to a well-known animal of the same genus, which, though doubtless descended from domesticated ancestors, have gradually assumed the wild condition; and it is worthy of special remark, that the anatomy of the wolf, and its osteology in particular, does not differ from that of the dog in general, more than the different kinds of dogs do from each other. The cranium is absolutely similar, and so are all, or nearly all the other essential parts; and to strengthen still further the probability of their identity, the dog and wolf will readily breed together, and their progeny is fertile. The obliquity of the position of the eyes of the wolf is one of the characters in which it differs from the dog; and although it is very desirable not to rest too much upon the effects of habit on structure, it is not perhaps straining the point to attribute the forward direction of the eyes in the dog, to the constant habit, for many successive generations, of looking towards its master, and obeying his voice." Mr. Bell adds, as another corroborative circumstance, the fact that the period of gestation in the dog and the wolf is the same—sixty-three days; while in the jackal it is fifty-nine days.

The opinion of so eminent and judicious a naturalist is certainly entitled to great weight; but while it is admitted that Mr. Bell has made a strong case, it must be observed that he is defective in several of his points. In the first place, it is assumed that all wild dogs are the descendants of a domestic race; but though, respecting some few, this may be true, yet it by no means follows that the assertion applies to all. The Buānsī, or wild dog of Nepal, described by Mr. Hodgson under the title of Canis primevus, may be given as an example. This animal, which is believed to be the origin of the domestic dog, and not its descendant, ranges from the Sat-lege to the Burhampootra; and seems to extend, with some immaterial differences, into the Vindyia, the Ghauts, the Nilgris, the Casiah Hills, and the chain passing brokenly from Mirzapore through south Bahar and Orissa to the Coromandel coast. In the zoological proceedings, it is stated, that of this race, although so wild as rarely to be seen, Mr. Hodgson has succeeded in obtaining many individuals. He is consequently enabled to describe not only the form and colours, but the manners also, which he does in great detail. Some of these he obtained produced young in captivity, having been pregnant when taken. The Buānsī, he observes, preys by night as well as by day, and hunts in packs of from six to ten individuals, maintaining the chase rather by its powers of smell than by the eye, and generally overcoming its quarry by force and perseverance. In hunting it barks like a hound; but its bark is peculiar, and equally unlike that of the cultivated breeds of dogs, and the strains of the jackal and the fox. Adults in captivity made no approach towards domestication; but a young one, which Mr. Hodgson obtained when it was not more than a month old, became sensible to caresses, distinguished the dogs of its own kennel from others, as well as its keepers from strangers; and, on the whole, its conduct manifested, to the full, as much intelligence as any of his sporting dogs of the same age.

W. A. Wooler, Esq., also gives an account of a wild dog from the Mahabalishwar Hills, in the Presidency of Bombay, and called there Dhole. The habits of this dog, in a state of nature, are similar to those of the Buānsī of Nepal, with which animal it is most probably identical. Colonel Sykes proves that the wild dog of the Dukhun, called by the Mahrattas
Kolsun, is the same as the Báansú of Nepal; the skulls and external characters exhibiting precisely the same formation and features. That gentleman further observes, that this dog differs from every wild species hitherto described. Its head is compressed and elongated; its nose not very sharp; the eyes are oblique, the pupils round, the irises light brown. The expression of the countenance is that of a coarse, ill-natured Persian greyhound, without any resemblance to the jackal, the fox, or the wolf; and, in consequence, essentially distinct from the Canis Quaio, or Sumatraensis, of General Hardwicke. The ears are long, erect, and somewhat rounded at the top; the limbs are remarkably large and strong in relation to the bulk of the animal, which is intermediate in size between the wolf and jackal. It hunts in packs; and in the stomach of one killed was found a portion of the Nylghau antelope.

Here, then, is a genuine wild dog, called in the different mountain districts it inhabits, Bálánú, Dhale, and Kolsun, of a sandy-red, or rufus colour, and destitute of the last small molar of the lower jaw. Colonel Baber, in a note subjoined to Colonel Syke's description in the Transactions of the Asiatic Society, states, that it was often seen by him on the western coast, and in the Balaghat district, where it is numerous. "As often," he adds, "as I have met with them, they have invariably been in packs of from thirty to perhaps sixty. They must be very formidable, as all animals are very much afraid of them. Frequently remains of hogs and deer have been brought to me, which had been taken overnight by these wild dogs. The natives assert that they kill tigers and cheetahs, and there is no doubt of the fact. It is quite correct that they are found in the Nilgiris, though only in the western parts. I, myself, was followed, while travelling between the Paitera river and Nadlabatt, a distance of eight or nine miles, by a pack of them; and had I not repeatedly fired off my pistols, they would certainly have carried away three or four terriers and Spanish dogs that were following me at the time. Two or three times I succeeded in getting young ones; but I did not keep them longer than three or four weeks, they were so very wild, as well as shy. It was only at night they would eat, and then most voraciously."

The Canis Quaio of General Hardwicke, is a red wolfish-looking dog in the Raungur Hills; and the Canis Sumatraensis is a wild dog of the same general character, found in Sumatra, but with ears less acutely pointed.

All accounts of wild dogs concur in stating the fact, that their colour is always sandy-yellow or red, a colour occasionally seen in animals of the domestic breeds, such as in one of the species of the Scotch terrier. That these wild dogs are genuine, we think there cannot be the slightest doubt; and, if so, what becomes of the wolf theory of Mr. Bell? Besides, we cannot see, by what possible power of inter-breeding, either a setter, or a spaniel, or a "Maltese lion dog," could be produced from a wolf. At the "National Dog Show," held at Islington, in 1862, every species of dog was exhibited, the whole comprising upwards of eight hundred specimens, and every one showing some different character, which made it distinct from another. Here the huge bearhound, down to the toy-terrier, of 2½ lbs. weight, was to be seen; and is it possible that the original of all these was a hungry gaunt wolf, with the sanguinary qualities of the tiger, and the ferocity of the hyena? The same, or similar arguments might possibly apply to the wild dogs of India; but inter-breeding from species of the same kind, is much more likely to produce variety, in the lapse of ages, than inter-breeding from species originally distinct, although bearing a close resemblance to each other. We do not, however, when we contend that these wild dogs are genuine, pretend to assert that any of them are the originals of any one of our domestic breeds. All we wish is to prove that there are genuine wild dogs; which fact being established, the necessity of looking to the wolf as the origin of the dog falls to the ground, for these wild dogs are not wolves.

In the next place, though the wolf and dog will breed together, their progeny, if fertile, as Buffon seems to prove, is so in a low degree only, the mixed race gradually failing, and becoming extinct. It has also yet to be seen, whether there exist a race of true wolves, the descendants of dogs, which have returned to their natural state, and reassumed their original characters. If the wild dogs, described above, and regarded as genuine, be really the
The descendants of a domestic stock, even then, seeing that they have resumed their original characters—as evidenced by their uniformity of size, figure, colour, and instincts—the argument that the wolf is the primeval type of the dog is at once nullified; for these rufus wild dogs are distinct from the wolf. While thus venturing to question the theory of Mr. Bell, and other eminent naturalists, we are not prepared to point out the origin or origins of the domestic dog; and we venture to say that the subject will always remain a Gordian knot, which science will never unravel. Buffon has eloquently observed, that "those species which man has greatly cultivated, whether belonging to the animal or the vegetable world, are, beyond all, those which are the most altered; and as the alteration is sometimes to such a degree, that we cannot recognise in them anything of their primitive form—such being the case with wheat, which has no resemblance to the plant from which it is supposed to have derived its origin—it is not impossible, that among the numerous varieties of the dog which we see in the present day, there is not one which bears a resemblance to the original type, or rather, to the first animal of the species."

Mr. Richardson, in his treatise on The Dog, also positively denies the assumed identity of structure between that animal and the wolf, set forth by Mr. Bell. He says the intestines of the wolf are considerably shorter than those of the dog, evidently marking him as an animal of more strictly carnivorous habits. The orbits are placed higher, and more forward in the skull. The proportion between the bones of the hind legs differs; so does the number of toes. The structure of the teeth is different; these being in the wolf much larger, whilst the molar teeth of the upper and lower jaw are adapted to each other; in the wolf, in a peculiar scissors-like manner, rendering them infinitely more serviceable for breaking bones—a structure not found in the dog.

"The wolf is not susceptible of the highest degree of domestication, and capable of great affection for mankind, which has been abundantly proved of the wolf." When has it been proved? I have seen many so-called "tame wolves," but never one that might be trusted; or that did not, when opportunity offered, return to his fierce nature and wild habits. The whelps, too, produced by these partially domesticated wolves, are not in the smallest degree influenced by the domestication of their parents. The Royal Zoological Society of Ireland had, some years ago, in their garden in the Phoenix Park, a pair of very tame wolves. These produced young, which became tame likewise, and, in their turn, produced cubs. The society very kindly presented me with one of the last-mentioned cubs, which, though only five weeks old when I took him from his dam, was as fierce and violent in his own little way as the most savage denizen of the forest. I brought up this animal among my dogs; for them he conceived a considerable degree of affection, or respect, perhaps; for submission was the most striking feature of his conduct towards them; and was, doubtless, induced by the frequent and substantial castigations he received. He never, it is true, exactly dared to attack me in front, but he once showed a disposition to do so when I pulled him down by the tail as he was endeavouring to get over the garden wall. He, however, on several occasions charged me from behind, when he thought my attention was otherwise engaged. He once only succeeded in inflicting a severe bite; and by this time I had utterly despaired of making anything of him: he was about eighteen months old; I sent him about his business. He subsequently fell into the hands of a showman, and assumed his proper character in the caravan. These observations, while they militate against the theory of Mr. Bell, concur with those of Buffon, in reference to the experience which that great naturalist obtained in rearing his own wolves. He found them, like Mr. Richardson, well enough up to their eighteenth month, but, after that period, the innate savageness of their nature began to discover itself, and there was little or no safety in their presence.

"As to dogs," continues Mr. Richardson, "when accident drives them to subsist on their own resources, thus rendering them wild, they assume feral characters; but as to their thus acquiring, in the course of a few generations, the habit and aspect, or the general similitude of wolves, I conceive it to be an assertion only, and one that has yet to be proved. Even such
dogs as have been thus driven into feral and independent life, will be found ever ready to acknowledge the control of man, and may, with comparatively little trouble, be induced to return to their allegiance to him. Nor will the whelps of such re-domesticated dogs be born wild, as is the case with the cubs of the tamest wolves. In the case of these dogs, circumstances, and not natural instinct, have driven them wild; and these circumstances ceasing to operate, domestication returns.

"How does it happen that the dog is to be met with in every quarter of the globe to which man has penetrated, while the true wolf has never yet been met with south of the equator? Further, are not several distinct species of wolf admitted to exist? Is there not more than one distinct species of wolf admitted by naturalists to exist in North America alone? It has not even been attempted to be proved that these species are identical; their distinctness has been more than tacitly admitted. Yet they resemble each other far more closely than any wolf does the dog. Has the dog, then, been derived from each and all of these wolves; or has the original wolf, origin alike of wolf and dog, been yet properly indicated? Should not this fact be duly ascertained prior to that in question?

"The wolf and the dog will not breed together in a state of nature. In their native forests they clearly will not, or the wild dog would not still remain distinct from the wolf, whose hair is in the immediate neighbourhood of his own. Man's effort and skill, combined with partial domestication, may, indeed, induce a union between them; but naturally they shun each other, and mutually exhibit a strong natural antipathy. Nor will these animals—the wolf and the dog—breed together, unless one of them, at least, be thoroughly domesticated. How else have all attempts to produce a breed between the wolf and Australian dingo so signally failed?"

The simple breeding together of animals, and the fertility of their offspring, is not a sufficient proof of identity of species. Mr. Hodgson has shown that the capra tharal—

* We have shown this in our previous pages.

† This we have also shown in our illustrative anecdotes.

the goat of Nepal—and the domestic goat will breed together. The hunchbacked zebu, of India, will breed with our common cattle, and the offspring is prolific. Pallas has stated that, in various parts of Russia, the sheep and the goat have bred together; whilst Chinese and European pigs, differing, according to Mr. Eyton, in important osteological particulars, will do so likewise.

In The Animal Kingdom, arranged after its Organisation, by Baron Cuvier, the following opinions, translated by Mr. Blyth, are given by that distinguished naturalist upon this subject. Speaking of the dog, and his supposed subjugation to the power and intelligence of man, he says,—"The domestic dog is the most complete, the most singular, and most useful conquest ever made by man, the whole species having become his property. Each individual is devoted to its particular master, assumes his manners, knows and defends his property, and remains attached to him until death; and all this, neither from constraint nor want, but solely from gratitude and pure friendship. The swiftness, strength, and scent of the dog have rendered him a powerful ally to man against other animals, and were even, perhaps, necessary to the establishment of society."

In reference to the origin of the dog, Mr. Blyth, in a note to his translation of the Baron's Régne Animal, argues in favour of the wolf theory. He says—"If the idea, which I conceive there is every reason to entertain, respecting the origin of the domestic dog be well founded, it is clear that a recurrence to a single wild type would be impossible. The dog is apparently a blended race, derived principally from the wolf, and partly from various other allied species. In the museum of the Zoological Society of London, there is a specimen of an Esquimaux dog (C. nubilus), which resembles the large American wolf so closely, that there can scarcely be any doubt of the connection which subsists between them; and it is well known, of the American wolves in particular, that if a young animal be surprised by a hunter, and suddenly menaced by his voice and manner, it will crouch to him, and implore his mercy in precisely the manner of a spaniel; so that only a little encouragement and kindness is required to gain its permanent attachment. Indeed many of them are killed
to obtain a proffered reward, by taking this (assuredly unworthy) advantage of their natural submissiveness. That the wolf possesses the mental qualities, and is capable of the same strong attachment to man as the most faithful dog, has been abundantly proved by the observations of M. F. Cuvier and others; and the unremitting persecution to which it has been necessarily subjected in Europe, for so many years, will sufficiently account for the savage and distrustful character which it exhibits when unreclaimed; though even then the germs of a better disposition are traceable in the permanent attachment of the male and female, and sociality of the young, till urgent necessity, or the annual period of dominant sexual excitement, subdues every milder propensity and acquired sentiment of friendship or disinterested affection.

"Instances occasionally happen of the dog returning by choice to a state of wildness, and assuming then, of necessity, the character ascribed to the wolf. I have known this to occur in a male pointer, and in a female greyhound: the latter was so fine a specimen of the breed, that, on being entrapped, it was thought desirable to obtain a litter from her, which was accordingly effected; but, while her puppies were very young, she managed to escape to the woods, and never returned: three of her progeny grew to be excellent hounds; but two others proved quite irreclaimable; and escaping from servitude, like their dam, were finally shot, for their destructive poaching propensities."

In the Zoology of Dr. Carpenter, we find it stated that "the common dog is a species of the genus *canis*, belonging to the family *canidae*, of the order *carnivora*, of the class *mammalia*, and the division *vertebrata*. From the information conveyed to us by the term *vertebrata*, we learn that it has an internal skeleton, with a jointed backbone and skull, containing the spinal marrow and brain, the centres of the nervous system; and that it has five senses, four extremities, and red blood. The knowledge that it is among the class *mammalia*, implies that it is a warm-blooded animal, breathing air, possessing a heart with four cavities, a complete double circulation, produces its young alive, nourishes them afterwards by suckling, and has the body, more or less, covered with hairs. By referring it to the order *carnivora*, we know that it is in its natural state a beast of prey, adapted by the formation of its teeth, and the digestive apparatus, to feed upon animal flesh; and by the structure of the extremities, to pursue and attack the animals which serve as its prey. As one of the family *canidae*, we know that it resembles, in some respects, the wolves, foxes, jackals, and hyænas, as well as the cats, in being *digitigrade* (that is, in walking on the ends of the toes), and that it differs from the cat in not being so much adapted to destroy its living prey, as to feed upon animals already killed; the mouth not being formed so exclusively for cutting and tearing as is the cat’s, and in the claws being neither so long and sharp, nor capable of being pushed forth or withdrawn, as in the feline tribes. Again, the dog differs from the fox and hyæna in certain peculiarities in the form of the teeth; but his relationship to the wolf is so close, that many naturalists have regarded them as sprung from the same stock. Then, while the dog belongs to a genus distinct from the hyæna and fox, it is identical with the wolf and jackal in generic character, and it may be that it does not even constitute a species distinct from the wolf. But, while some characters are constant in each race, others may undergo great variation; so that, within the limits of one species, we may have a large number of varieties, or breeds, marked by differences much greater than those which, in other cases, are held to distinguish species. This is especially the case in domestic animals; and in none is it shown more strongly than in the dog. How different, for example, are the greyhound, the mastiff, and the bloodhound! We should scarcely imagine that any period of time, or external influence, could ever convert one of them into the other. Yet the zoologist feels no hesitation in affirming that they had one common origin; since it is found that their distinct forms are preserved only so long as they are matched in breeding with forms of the same kind. Hence there is no difficulty in reconciling the diversities actually existing among the various races of dogs with the idea of one common origin, of which they are modifications. When and how the several breeds arose, is less easily determined."

Among so many conflicting statements, it is,
perhaps, utterly impossible to determine the true origin of the dog. Mr. Bell, and others, argue for the wolf theory. Mr. Hodgson and others do the same for the primitive wild dog theory; and Professor Kreischer does the same for the jackal theory. He says that there is a kind of jackal in the Frankfort Museum, exemplifying all the types of the ancient Egyptian dog. To this theory of the jackal, however, we cannot, for a moment, lend ourselves. To be sure, it is said that the manners of this animal bear a very close resemblance to those of the dog. When taken young it soon becomes domesticated; attaches itself to mankind, wags its tail when pleased, and distinguishes its master from other persons. It likes to be fondled and patted with the hand; and, when called by name, will answer to it, and leap on a chair. It drinks as the dog does, by lapping, and it will eat readily from the hand: it is even fond of playing with dogs, and eats bread with eagerness. These qualities induced Mr. Pennant to think, with Professor Kreischer, that the various races of the dog were indebted to the jackal for their origin. To this pleasing canine portrait, however, that of Buffon presents a very great contrast. He says that the jackal is stupid and voracious; that it is very difficult to be tamed; and that he had one which was kept for nearly a year, when neither food nor caresses could mollify the fierceness of its disposition. Although it had been taken young, and reared with the utmost care, it would suffer no one to touch it, and would bite at any one indiscriminately. When occasionally allowed a little liberty, it amused itself by leaping on the tables, and devouring everything suitable to its palate. Its voracity, he says, was enormous. If it could get nothing better, it would eat the leather for harness, and boots or shoes. It would eat the most putrid bodies, disinter the dead, attend caravans, and follow armies, to feast on the remains of the fallen or the slain. Such a brute does not appear, to our mind, to exhibit a single trait of the dog, to the extent that would lead us to coincide with the theory which would place the jackal as the original of that generous animal; but, as the opinions of eminent naturalists are so different from each other, it is difficult to decide between them.

Another theory advanced is, that the shepherd's dog is the original type; but it is thus combated by Mr. Richardson:

"Many naturalists, and these natives of different countries, have advanced this theory, and still they have all employed the one designation in indicating their favourite type—viz., the shepherd's dog. I must here first take the liberty of inquiring what shepherd's dog? for shepherd's dogs differ most materially from each other. Buffon stood up for the originality of the matin, or shepherd's dog of his own country. Later writers, copying more or less from him, have adhered to the theory of the sheep-dog origin, while they have forgotten the difference which exists between their own national sheep-dogs and those indicated by Buffon. Truly there exists but little similitude between the tailless, woolly-looking animal, the sheep-dog of England, the fox-like colley of Scotland, the gaunt and short-haired cur of Ireland, the matin of Buffon, the noble, stately, and powerful sheep-dog of the Pyrenees, the guardian of the flocks of the Abruzzi, the gigantic mastiffs, the herd-dogs of the Himalaya mountains, and, in short, between various other sorts of sheep-dog, used for tending flocks in as various portions of the known world. Shall we assume the original type to have been the sheep-dog or matin of France, or the more graceful colley of Scotland? Are we to believe that a brace of either of these dogs were the progenitors of the entire canine race? Did the gigantic bear-dog, the noble Newfoundland, the courageous and powerful mastiff, the slender and rapid greyhound, the stunted yet formidable bulldog, the diminutive and sensitive Blenheim spaniel, and the still more diminutive, and now almost extinct, lion-dog of Malta—all arise from a brace of curs? If they did, to what now are we to attribute the varieties at present existing? We are told to climate and breeding. As to breeding, how could it operate when there was but a single pair to breed from? How, if the varieties of the dog proceeded but from one original type, could development thus be produced, extending beyond the limits of the faculties and powers proper to that type? Will change of climate ever convert a greyhound into a bulldog? Will it truncate the muzzle, raise the frontal bones, enlarge the frontal sinuses, or effect a positive alteration of the posterior
brances of the lower maxillary bones? Or will change of climate, on the other hand, operate to convert a bulldog into a greyhound, produce a high and slender form, diminish the frontal sinuses, deprive the animal of the sense of smell, at least comparatively, together with courage and other moral qualities depending on organisation? I say nothing: I only ask my intelligent readers—do they believe this possible? Thus far, a very eminent naturalist, Colonel Hamilton Smith, goes with me, hand in hand; all that I have adduced he admits; but here we unfortunately part company. Colonel Smith seeks to account for these differences by calling in the intervention of a supposed admixture of wolf, fox, or hyæna, &c. He admits an originally-formed dog, and one variety only; and refers for the alterations that have taken place in him to crossing with these wild animals. Now I consider this theory as even less tenable than that of the wolfish or vulpine origin of the dog, as the colonel is obliged to bring several races of wild dogs to his aid; and, may I venture to inquire, where is their origin? Besides this, we have to refer to the decided antipathy subsisting between these animals in a state of nature, and thus effectually precluding intermixture, unless through human intervention and agency, which clearly was never exerted in that condition for this purpose.

"It is," says Mr. Richardson, "in far remote ages of 'The Earth and Animated Nature' that we have to seek for traces of the origin of this sagacious and generous animal, which has enjoyed the especial privilege and well-merited honour of being, par excellence, the friend of man."—In this opinion we concur. We further believe—for it must resolve itself into a matter only of belief where all reasoning is contradictory, and therefore in a great measure nugatory—that, however close his alliance may be to the wolf or the jackal, neither of these animals are his original. He has, in our opinion, an original of his own; and, however thick may be the veil which shrouds this in obscurity, his intelligence being next to that of man, stamps him as a creation as distinctly original as that of the half-reasoning elephant.

So nearly akin is the intelligence of the dog to reason, that we are sometimes puzzled to account for the actions which result from it.

"Lo! the poor Indian, whose un infuri'd mind
Sees God in clouds, and hears him in the wind,
*   *   *   *   *
And thinks, admitted to that equal sky,
His faithful dog shall bear him company."

The poets of different ages and of various lands would seem to have delighted in commemorating the virtues of this favourite animal. Of this we have already given an illustration from the Homeric poems, and we will now give one from the Virgilian Georgies:—

"Nor last forget thy faithful dogs; but feed
With fattening whey the mastiff's gen'rous breed,
And Spartan race, who, for the fold's relief,
Will prosecute with cries the nightly thief;
Repulse the prowling wolf, and hold at bay
The mountain robbers rushing to the prey.
With cries of hounds thou may'st pursue the fear
Of flying hares, and chase the fallow deer;
Rouse from their desert dens the bristled rage
Of boars, and beamy stags in toils engage."

Walter Scott was also passionately attached to dogs; and, in some of the most graphic and picturesque scenes in his beautiful novels, several of these find a prominent place. Their fidelity and sagacity, exemplified on many occasions, were to him a source of great enjoyment. In allusion to these qualities, as exhibited by one, in the case of a traveller who had been dashed to pieces by falling from a precipice of Helvellyn, he says—

"Nor yet quite deserted, though lonely extended,
For faithful in death, his meek favourite attended,
The much-loved remains of her master defended;
And chased the hill-fox and the raven away.
How long didst thou think that his silence was slumber?
When the wind moved his garments, how oft didst thou start?
How many long days and long weeks didst thou number,
Ere he faded before thee, the friend of thy heart?"

The circumstances which suggested this poem were detailed to a tourist by one of the guides who conducts visitors to the summits of Skiddaw and Helvellyn. The unfortunate man who perished amidst these solitudes, was a resident of Manchester, who was periodically in the habit of visiting the lakes, and who, confiding in his knowledge of the country, had ventured to cross one of the passes of Helvellyn, late in a summer afternoon, in company only with his faithful dog. Darkness, it is supposed, came on before his expectation; he wandered from the track; and fell over the rocks...
FOR MOUNTAIN, FIELD, AND FARM.

into one of those deep recesses where human foot never treads. The dog was found by the side of his master's body, after many weeks' fruitless search. The man who told the story concluded with the pious exclamation of—

"God knows how the poor beast was supported so long."

Wordsworth has also written on this subject; but his poem is too long for quotation here; the following, however, are four of the stanzas most appropriate to our subject.

"A barking sound the shepherd hears,
A cry as of a dog or fox;
He halts and searches with his eyes
Among the scattered rocks:
And now at distance can discern
A stirring in a brake of fern;
From which immediately leaps out
A dog, and yelping runs about.

"The dog is not of mountain breed;
Its motions, too, are wild and shy;
With something, as the shepherd thinks,
Unusual in its cry:
Nor is there any one in sight,
All round, in hollow or in height;
Nor shout nor whistle strikes his ear;
What is the creature doing here?

"It was a cove, a huge recess,
That keeps till June December's snow;
A lofty precipice in front,
A silent tarn below.

Far in the bosom of Helvellyn,
Remote from public road or dwelling
Pathway or cultivated land,
From trace of human foot or hand.

"But hear a wonder now, for sake
Of which this mournful tale I tell!
A lasting monument of words
This wonder merits well.
The dog, which still was howling night,
Repeating the same timid cry,
This dog had been, through three months' space,
A dweller in that savage place."

As an appropriate close to this chapter, we will give the epitaphs written by two of our most celebrated poets, upon their favourite dogs. "Maida," the first, was the deer-hound of Sir Walter Scott, presented to him by Macdonald of Glengarry, and was a splendid animal. He lies buried at the gate of Abbotsford, of which he was long the guardian:

"At thy master's gate here, Maida,
Lovely dost thou rest;
Light the low-relievo marble
Lie upon thy breast."

"Boatswain" was the favourite Newfoundland of Lord Byron:

"The poor dog! in life the firmest friend,
The first to welcome, foremost to defend;
Whose honest heart is still his master's own—
Who labours, fights, lives, breathes for him alone."

CHAPTER II.

HISTORY OF THE DOG.

The Canidae, or Canine family, includes the Dog, the Wolf, the Jackal, the Fox, and the Lycaon; in other words, all those animals which Linnaeus assigns to his genus Canis; and which, though agreeing in dentition, and in the digitigrade structure of the feet, may, nevertheless, with propriety, be divided into sub-generic groups. In all, the muzzle is elongated; the bony palate terminates in a line with the hinder margin of the posterior molars, in this respect differing from that of other carnivora; and there are two true molars on each side of the upper and lower jaws. The genus Megalotis, in the form of the lower jaw, in the dentition, and in the prolongation of the bony palate, offers an exception to the general rule.

Dental formula:—Incisors, $\frac{6}{6}$; Canines, $1-1$; Molars, false $3-3$, carnassiers $1-1$, true $2-2$, $2-2 = 12$.

The true molars below are small, the last being even minute, as is the first false molar, and often dropping out early.

379
Fore feet, with five toes; hind feet, with four toes, and sometimes a fifth on the tarsus; claws not retractile.

The following is the arrangement of the groups into which the breeds of the domestic dog have been thought to resolve themselves:

1. Dingo—semi-domestic?
2. Equineus dog?
3. Hare Indian’s dog?

To what groups these respectively belong is not very clear; probably to the first or second of the following groups:

1. Shepherd’s do

2. Siberian.

3. Pomeranian.

4. Icelandic, &c.

5. Terrier, rough and smooth.

6. Turnspit.

7. Barbary dog.

8. Lurcher, &c.

9. Great Danish dog.

10. Irish wolf-dog.

11. Scotch greyhound, or deer-hound.

12. English ditto.

13. Italian ditto.

15. Alphonian dogs, &c.

17. Water-spaniel.

18. Rough water-dog.

20. Italian wolf-dog.

22. Labrador dog.

23. Alpine dog, &c.

24. Pointer.

27. Fox-hound.

28. Old English hound.

29. Bloodhound.

31. Cuban mastiff.

32. Mastiff.

33. Spaniel.

34. Bloodhound.

35. African hound, &c.

36. Cuban mastiff.

37. Mastiff.

38. Canis lupus.

39. Dugue de forte race of the Romans, it is not to be wondered at their sending to Britain for our old indigenous mastiff.

In the Scriptures there are abundant allusions to the dog. Some of these are to be found in Exodus xxii. 31; 1 Kings xxii. 19 and 23; 2 Kings ix. 35, and elsewhere. The passages of greatest force are:—“In the place where the dogs licked the blood of Naboth, shall dogs lick thy blood, even thine;” and, “The dogs shall eat Jezebel by the wall of Jezreel.” These recall the picture of a scene painted in modern days by a poet, who had travelled in Greece and Turkey, and whose wonderful pen drew, with magical power, the habits of the masterless dogs that “wander up and down for meat, and grudge if they be not satisfied.” The passage is in Byron's Siege of Corinth:

“"He saw the lean dogs beneath the wall,
   Hold o'er the dead their carnival;
   Gorging and growling o'er carcass and limb,
   They were too busy to bark at him.
   From a Tartar’s skull they had stripp’d the flesh,
   As ye peal the fig when the fruit is fresh;
   And their white tusks crunch’d o’er the whiter skull,
   As it slipt through their jaws when their edge grew dull,
   As they hazily mumbled the bones of the dead,
   As they scarce could rise from the spot where they fed;
   So well had they broken a lingering fast
   With those who had fallen for that night’s repast.”

In Egypt the dog was a favourite, and carefully bred, and, as the paintings of that people prove, there were several breeds. It would
appear, indeed, that some kinds were regarded with religious veneration, and embalmed after death. Mummies of them are still found. There would seem to have been in this country of natural and artificial physical wonders, different kinds of dogs. There are representations of hounds resembling our greyhound; of pet-domestic dogs, with sharp ears, and curly tails; of short-legged turnspits; of watch-dogs; of hunting-dogs, and other descriptions of the canine race. Indeed, what, physically speaking, were these people without, from the Pyramid of Cheops down to the smallest representations of humanity, in black marble statuary?—from innumerable colossal figures of kings that might rival the proportions of Jupiter in our limited conceptions, down to the minutest representation of the species—scaribaces—that human ingenuity and fingers could fashion? They had, also, of "live-stock," the crocodile, "the great dragon of the river," the emblem of the Nile, and the symbol of Egypt; they had the beautiful ibis and the pelican, emblem of maternal love; in short, what had they not? and, as they represented these things in sculpture, so did they represent their dogs, from which representations we are, at this day, enabled to decide, in some measure, the nature of the various breeds of the animals of which they were possessed. The modern greyhound of Arabia so closely resembles the delineations of the ancient greyhound, that we cannot doubt their affinity. The Egyptians, in the chase, used the bow and spear, and intercepted the game as it fled before the hounds, discharging their arrows whenever it came within range. When a fierce antelope, as the Lencoryx, was brought to bay, the hunter gallantly used his spear, as the bow-hunter of the middle ages did in Europe. On the level plains of Egypt the chasseur often followed in his chariot, urging his horses to the full speed, and endeavouring to meet the game, or place himself in the direction the dogs were forcing it to take, with his bow and arrows ready. It was, perhaps, the partiality evinced by the Egyptians for the dog, that led the Israelites to regard it with abhorrence, as an unclean animal; in which feeling they have been followed by the Mohammedans. Be this as it may, Palestine "is the country in which this animal has the longest been refined that entire domestication with man which he has enjoyed in most other lands; in other words, the treatment of the dog has almost always, in Palestine, been such as it has only in other countries been subject to, since the propagation of the Moslem faith. And since the ideas concerning dogs have been much the same with the ancient Jews and modern Moslems, there is no doubt that the existing practices of the latter, illustrate the ancient practices of the former. Among both, we trace the despised, but not maltreated dog of the streets; and among both we discover that, with every predisposition to do without them, certain breeds of dogs have forced their services upon man, from the indispensable nature of their help in hunting and in guarding the flocks."

The street dogs, called Pariah dogs in India, have excited the attention of all travellers in that country, as well as in Turkey, and the whole of the Levant. They roam the streets of towns, cities, and villages, owned by no one; but, for their services in clearing away carrion and offal, are universally tolerated. Allusions are made to them in the earliest records of antiquity. Homer describes them in conjunction with vultures, as feeding upon the slain:

"Whose limbs, unburied on the naked shore,
Devouring dogs and hungry vultures tore."

These dogs herd together in troops, and keep to their respective districts; they display all the qualities and propensities of their race, and if they are fierce and venomous, it is because they are left to their own resources; since, to become at once domestic, they require only to be owned and noticed. Colonel Sykes, speaking of the Pariah dog of Dukhun, observes that it is there very numerous, and not individual property, but breeds in the towns and villages unmolested. He remarks that the Turnspit dog, long-backed, with short crooked legs, is frequently found among the Pariahs. There is also a petted minute variety of the Pariah dog, usually of a white colour, with long silky hair, corresponding to a common lap-dog of Europe, which is taught to carry flambeaux and lanterns. The last variety noticed, is the dog with hair so short as to appear naked, like the Barbary or Egyptian dog. It is known to Europeans by the name of the Polygar dog. Of the Domesticated
dogs, Colonel Sykes states, that the first in size and strength is the Brinjaree dog, which somewhat resembles the Persian greyhound, but is much more powerful.

The properties of the dog, however, will be treated of further on in this work; meanwhile we will here instance the general intelligence, fidelity, and sagacity of this animal, by a few illustrative anecdotes, which place him in his relationship with man in a striking point of view. There are few who, from their own experience, cannot bear testimony to the good qualities of the dog! It has been somewhere said, "that man is the god of the dog," for to man he looks up with reverence and affection, and the praise of his master is his richest reward. Is this instinctive attachment to the human species acquired, or is it an original impulse implanted in its nature, by the All-wise Creator, for man's benefit, so that in the primitive condition of society he might have a friend and assistant, all-important in the chase, and in the extirpation of wild beasts, which he can settle in a land or found a colony, he must drive to a distance or destroy?

In reference to the domesticated races, we have no animal so completely subservient to all the purposes or the wants of man, in so far as obedience, attachment, and alliance can be rendered by an inferior to a superior. The anecdotes which are recorded as illustrative of these qualities, would form a canine library of no mean pretensions. In Mr. Burchell's Travels in Africa, we have the character of a pack of dogs thus given:—

"Our pack of dogs consisted of five-and-twenty of various sorts and sizes. This variety, though not altogether intentional, as I was obliged to take any that could be procured, was of the greatest service in such an expedition, as I observed that some gave notice of danger in one way, and others in another. Some were more disposed to watch against men, and others against wild beasts; some discovered an enemy by their quickness of hearing, others by that of scent; some for speed in pursuing game; some were useful only for their vigilance and barking; and others for their courage in holding ferocious animals at bay. So large a pack was not, indeed, maintained without adding greatly to our care and trouble, in supplying them with meat and water, for it was sometimes difficult to procure for them enough of the latter; but their services were invaluable, often contributing to our safety, and always to our ease, by their constant vigilance, as we felt a confidence that no danger could approach us at night without being announced by their barking. No circumstances could render the value and fidelity of these animals so conspicuous and sensible as a journey through regions which, abounding in wild beasts of almost every class, gave continual opportunities of witnessing the strong contrast in their habits, between the ferocious beasts of prey, which fly at the approach of man, and these kind, but too often injured companions of the human race. Many times, when we have been travelling over the plains where those have fled the moment we appeared in sight, have I turned my eyes towards my dogs to admire their attachment, and have felt a grateful affection towards them for preferring our society to the liberty of other quadrupeds. Often, in the middle of the night, when all my people have been fast asleep around the fire, have I stood to contemplate these faithful animals lying by their side, and have learnt to esteem them for their social love of mankind. When wandering over pathless deserts, oppressed with vexation and distress at the conduct of my own men, I have turned to these as my only friends, and felt how much inferior to them was man when actuated only by selfish views.

"The familiarity which subsists between this animal and our own race, is so common to almost every country of the globe, that any remark upon it must seem superfluous; but I cannot avoid believing that it is the universality of the fact which prevents the greater part of mankind from reflecting duly on the subject. While almost every other quadruped fears man as its most formidable enemy, here is one which regards him as its companion, and follows him as its friend. We must not mistake the nature of the case; it is not because we train him to our use; and have made choice of him in preference to other animals, but because this particular species feels a natural desire to be useful to man, and from spontaneous impulse attaches itself to him. Were it not so, we should see, in various
countries, an equal familiarity with various other quadrupeds, according to the habits, the taste, or the cuprice of different nations. But everywhere it is the dog only that takes delight in associating with us, in sharing our abode, and is even jealous that our attention should be bestowed on him alone; it is he who knows us personally, watches for us, and warns us of danger. It is impossible for the naturalist, when taking a survey of the whole animal creation, not to feel a conviction that this friendship between two creatures so different from each other, must be the result of the laws of nature; nor can the humane and feeling mind avoid the belief, that kindness to those animals, from which he derives continual and essential assistance, is part of his moral duty."

These sentiments are those of a man who was everywhere surrounded with danger, and who was in the very best situation for appreciating the nature and value of the dog. He saw in him the most constant, vigilant, and faithful of associates; his humanity expanded as he reflected on his qualities, and he could not help giving the preference to the dog over his own species for faithfulness and friendship. The passage in which this appears is worth repeating and remembering by those who may look upon this generous animal with an unfavourable or unfriendly eye. "When wandering over pathless deserts, oppressed with vexation and distress at the conduct of my own men, I have turned to these as my own friends, and felt how much inferior to them was man when actuated only by selfish views."

The Newfoundland dog has long been famed for his sagacity and the humanity of his performances.

A native of Germany, fond of travelling, was pursuing his course through Holland, accompanied by a very large one of this species. Walking one evening on a high bank, which formed one side of a dike, or canal, so common in that country, his foot slipped, and he was precipitated into the water, and, being unable to swim, he soon became senseless. When he recovered his recollection, he found himself in a cottage on the opposite side of the dike to that from which he had fallen, surrounded by peasants, who had been using the means so generally practised in that country for restoring animation. The account given by the peasants was, that one of them, returning home from his labour, observed, at a considerable distance, a large dog in the water, swimming, and dragging, and sometimes pushing something which he seemed to have great difficulty in supporting, but which he, at length, succeeded in getting into a small creek on the opposite side to that on which the men were.

When the animal had pulled what he had hitherto supported as far out of the water as he was able, the peasant discovered that it was the body of a man. The dog having shaken himself, began industriously to lick the hands and face of his master, while the rustic hastened across; and, having obtained assistance, the body was conveyed to a neighbouring house, where the usual means of resuscitation soon restored him to sense and recollection. Two very considerable bruises, with the marks of teeth, appeared—one on the shoulder, the other on the nape of the neck—whence it was presumed that the faithful animal first seized his master by the shoulder, and swam with him in this manner for some time; but that his sagacity had prompted him to let go his hold, and shift his grasp to the neck, by which he had been enabled to support the head out of the water. It was in the latter position that the peasant observed the dog making his way along the dike, which, it appeared, he had done for a distance of nearly a quarter of a mile. It is therefore probable that this gentleman owed his life as much to the sagacity as to the fidelity of his dog.

A large Newfoundland dog, belonging to Glasgow, offers another instance to the many on record of the extraordinary sagacity of dogs. It seems, that being, like human juveniles, sometimes rather fond of fun, he required to receive occasional discipline, and for that purpose a whip-shaft was kept beside him, which was at certain times applied to him. He evidently did not like this article, and was found occasionally with it in his teeth, moving sily to the door with it. Being left at night on the premises, he found the hated article, and thrust the small end below the door, but this he could not do with the thick part. A few nights afterwards, the whip-shaft was left beside him, and was never seen again. He
had put the small end below the door, and some one had pulled it out. On the dog being asked where it was, he looked very guilty, and slunk away with his tail between his legs. This same dog has his provisions brought to him in a tin can. Taking a walk, he saw a child carrying a vessel exceedingly like his; when he quietly seized it by the handle, and carried it to his quarters, the child holding on, and screaming all the way. When shown his own he seemed quite ashamed of his mistake, and allowed the frightened child to go with the tin he had mistaken for his own. This animal is in the habit of begging money from his biped acquaintance, with which he marches to a baker's shop and buys bread, which he carries home and eats when hungry.

It was but the other day that we read of an anecdote strongly indicative of the fidelity of an Irish dog towards his master, who, in the city of Dublin, was overcome by the potent beverage which, as it is a favourite liquor of other parts of Ireland, so does it hold a high place in the estimation of at least some of the inhabitants of that city. A respectable-looking man, belonging to the middle classes of life, tottered down Donegal-street, apparently oblivious to everything. A handsome dog, of the caste known as spaniel, followed at his heels, whimpering most mournfully, evidently wishing him to retrace his steps, and displaying a great deal more regard for the man than he did for himself. The man at last tumbled down on the steps opposite the parish church, his watch being thrown out of his pocket by the fall. The dog, with an instinct which, if inferior to the reason exhibited in a higher order of beings, certainly exhibited a more exalted notion of affection than is portrayed in many, lay down on his master's breast, clutching the watch between his two fore feet. A crowd gathered round the senseless man; but the dog, considering himself his protector, would let no one approach him. A constable came up; but the dumb animal, recognising no person, would not let the policeman go near him; the dog guarding every pore of the baton with his head. The barking of the spaniel at last awakened the drunkard, who, with much difficulty, got the watch into his pocket, and staggered on, the faithful animal barking and wagging his tail with delight.

There is, perhaps, a still more extraordinary instance of sagacity; and, as it is of a rare description, it merits a place in these pages. It is from the *Recollections of a Sportsman*, by Lord W. Lennox. "A short time ago, a dog, well known to the railway officials, from his frequent travelling with his master, presented himself at one of the stations on the Fleetwood, Preston, and Longridge line. After looking round for some length of time among the passengers, and in the carriages, just as the train was about to start he leaped into one of the compartments of a carriage, and laid himself down under the seat. Arriving at Longridge, he made another survey of the passengers, and, after waiting until the station had been cleared, he went into the railway station hotel, searched all the places on the ground-floor, then went and made a tour of inspection over the adjoining grounds; but, being apparently unsuccessful, trotted back to the train, and took his old position just as it moved off. On reaching the station from which he had first started, he again looked round as before, and took his departure. It seems that he now proceeded to the general railway station at Preston, and, after repeating the looking-around performance, placed himself under one of the seats in a train which he had singled out of many that are constantly passing in and out, and, in due time, arrived in Liverpool. He now visited a few places where he had been before with his master, of whom, as it afterwards appeared, he was in search. Of his adventures in Liverpool little is known; but he remained all night, and visited Preston again early the next morning. Still, not finding his missing master, he, for the fourth time, "took the train"—this time, however, to Lancaster and Carlisle; at which latter place the sagacity and faithfulness of the animal, as well as the perseverance and tact he displayed in prosecuting his search, were rewarded by finding his master."

Of the spaniel races there are many recorded instances of wonderful sagacity; and to some of them has been ascribed the possession of even an organ of music. On a few of this family, fine music has been known to produce an apparently painful effect, causing them gradually to become restless, to moan piteously, and, finally, to escape from its presence with every sign of
suffering and distress. Others have been seen to sit and listen to music with seeming delight, and even to go every Sunday to church, with the obvious purpose of enjoying the solemn and powerful strains of the organ. All these displays, however, of musical tendencies on the part of the canine race, are as nothing in comparison with the following, which a German paper gave an account of some time back. Frederick S——, a musical amateur of Darmstadt, in the grand duchy of Hesse, possesses a female spaniel, which has become a strange source of terror to all the mediocre musicians of the place and its vicinity. Having acquired a competency by commercial industry, Mr. S—— retired from business, and devoted himself, heart and soul, to the daily and hourly enjoyment of his favourite science. Every member of his little household was by degrees involved, more or less, in the same occupation, and even the housemaid could, in time, take a part in a chorus. One individual alone in the family seemed to resist this musical entrancement; this was a small spaniel, the sole specimen of the canine race in the mansion. Mr. S—— felt the impossibility of instilling the theory of sounds into the head of Poodle, but he firmly resolved to make the animal bear some part or other in the general domestic concert; and by perseverance, and the adoption of ingenious means, he attained his object. Every time that a false note escaped either from instrument or voice—as often as any blunder, of whatever kind, was committed by the members of the musical family (and such blunders were sometimes committed intentionally)—down came its master’s cane on the back of the unfortunate spaniel, till she howled and growled again. By-and-by, simple menaces with the stick were substituted for blows; and, at a still more advanced period of this extraordinary training, a mere glance of Mr. S——’s eye was sufficient to make the animal howl to admiration. In the end, she became so thoroughly acquainted with, and attentive to, false notes, and other musical barbarisms, that the slightest mistake of the kind was infallibly signalised by a yell from her, forming the most expressive commentary upon the misperformance. When extended trials were made of the animal’s acquirements, they were never found to fail, and she became, what she still is, the most famous, impartial, and conscientious critic in the duchy of Hesse. But, as may be imagined, her musical appreciation is entirely negative; if you sing with expression, and play with ability, she will remain cold and impassible. Although nothing can be said in favour of the dog while in a state of nature, still, after he has received an education from man, the whole world will bear testimony to his immense value. Volumes would not suffice to contain instances of his services to the human race. A man and his dog may almost be considered as component parts, each working for the other, whether in heat or in cold, in tempests or in calms. The blind confide in him; the lame have his support; the rich are proud of him; and, too often, the poor man has nothing but his dog to give him consolation.

These instances of sagacity and intelligence, as displayed in this animal, are, in numberless instances, equalled by his courage. Mr. Lloyd, in his Field Sports, says, that “for bear-shooting, a first-rate dog is invaluable; but such are rarely to be found; indeed, with the exception of Paijas, I never met with one at all deserving of that character. That gallant hound, however, was, in his better days, everything I could wish. In one instance I knew him to worry a large bear for nearly eight successive hours; and during a considerable part of this time no person was with him. Sometimes he was alongside the beast; at others, a little ahead, and then hanging on his rear; and all this while making the forest ring again with his yells. Though he usually conducted his attacks with caution, in consequence of the mauiling he received from a bear in his younger days, his courage at times, during the chase I speak of, got the better of his prudence; for, on hearing my shots, he seldom resisted the temptation of having a snap at the haunches of his rugged antagonist. In this case, the bear would swing himself round with wonderful agility, dash at the dog, and strike out with his paws in much the same manner as a cat; but Paijas, being up to these manoeuvres, always took care to beat a timely retreat.

“By a dog thus incessantly harassing a bear, the sportsman is enabled to make many a short cut; his continual attacks, besides, often bring the beast to a stand-still; in which
case, one can generally approach within range of him. On such occasions a good dog is an immense safeguard to a person; as, should he unhappily fall into the jaws of the beast, his faithful follower might be the means of saving his life; for the dog seldom hesitates to fix at once upon the bear; and, by so doing, he often succeeds in drawing the attack from his master to himself.

"High-couraged dogs are not unfrequently killed by the bear during the chase; for, if the beast once gets them within his grasp, he, in most cases, quickly annihilates them. Several instances of the kind have come to my knowledge.

"It is said, that when the bear is pursued by dogs, he, at times, becomes so much enraged, that he takes hold of the nearest stick or stone he can lay his paws upon, and casts it at them. According to Mr. Nilsson, indeed, when the bear is attacked by the hunter, and whilst beating a retreat, he satisfies himself by throwing these missiles at his adversary. It is reported that bruin is a bad marksman; for, instead of sending his weapon in the direction of his opponent, he not unfrequently whizzes it over his own head. As I never witnessed an exploit of the kind on the part of a bear, I am by no means inclined to vouch for the truth of these stories."

In following the elk, the Northern chasseur must have his dogs, which he often slips from the couplings, and which not unfrequently bring the old males to bay. In hunting this animal, considerable art is necessary; and the eagerness and length of time with which they pursue the game are astonishing. The dog must always be allowed to start the elk; for, should the latter once get sight or scent of the sportsman, he usually goes off at his best pace.

The great inconvenience of slipping a dog on these occasions is, that if he should be good for anything, and the elk does not stand to bay, he will hardly ever desist from pursuing the animal; and thus the sportsman may be thrown out altogether.

To guard against a circumstance of this kind happening, the Northern chasseurs—there generally being two or more in company on these occasions—are not unfrequently provided with a second dog, which they retain in his leash. When, therefore, they can no longer hear the challenges of the dog that is loosed in the distance, the other enables them to continue the pursuit. Sometimes, however, dogs go off altogether from their masters. "I have heard of instances of their pursuing the elk such great distances, that they have been lost to their owners for days and days together, and have perhaps cast up at last in an altogether different part of the country."

Of the determination and spirit of the dog, even in pursuing and attacking the most ferocious animals, there are many examples on record. Recently, a French journal chronicled the following incidents in a wild boar hunt:—

The pack of hounds of M. Rattier de Verveines, twenty-five in number, lately hunted a huge wild boar in the forest near this town—Alençon—but, after three hours' chase, could not bring it to bay, though it stopped now and then to attack the dogs. Twelve fresh hounds having been set on it, it at last stopped, and the dogs attacked it with great determination. It, however, ripped up several, and threw others in the air. One of the keepers having arrived, fired his carbine, but only broke one of the fore feet of the animal. The chief keeper then arrived, and fired two balls at its head, without, however, producing any effect. He, however, re-loaded, and then lodged one ball in the boar's muzzle, and the other behind his ear. The last proved mortal, the animal falling dead. It was then found that two of the dogs were dead, ten more mortally wounded, and that several others were more or less injured. The boar weighed about 3 cwt.

The terrier has long been famous for his game and hunting propensities. Recently a stone-cutter, engaged at the Bodelwyddan church, near St. Asaph, was taking a walk in some fields, accompanied by a dog, of the crossbred terrier breed. The dog was hunting along a small rivulet, which ran at the bottom of a field, when a large male otter made his appearance, running along the course of the brook. The man was frightened, never having seen such an animal before; but the dog immediately attacked him, when a battle ensued, the other dragging the dog to a small pool, about three or four feet deep, evidently with the intention of drowning him. The man prevented this by laying hold of the dog, and dragged
them both out fastened together; when again, on *terra firma*, they fought desperately for half-an-hour, mutually separating to draw breath; then the otter took advantage of this pause, and made for the brook again. The dog, by this time, was dreadfully lacerated—his nose and lips cut through, and otherwise bruised. The man perceiving this, took up a hedge-stake, and gave the otter a severe blow on the head. The dog then went at him again, the man occasionally assisting with his stick; and between them both the otter was killed, after an hour's hard fighting. It was a formidable-looking animal, and measured, from the nose to the tail, 3ft. 10in.

It is to be regretted that an animal possessed of such generous impulses, however, is sometimes found to act contrary to all expectation. The following is an instance of this, and places the mastiff, on this occasion, in a very unfavourable point of view:—A lady, of some property, residing in the Rue des Vignes, at Vaugirard, was possessed of a huge mastiff, which, being very savage, had to be kept constantly chained up, but which she prized because it had belonged to her late husband. One morning, according to custom, she took the animal his food, but he seemed more indolent than usual, and she gave him a beating. Watching an opportunity, he suddenly rushed on her, threw her down, dragged off the greater part of her clothes, and bit her dreadfully in the breast, arm, and one of the legs; in fact, tearing away fragments of the flesh. The lady's cries attracted some of the neighbours to the spot, and they rescued her. Although suffering dreadfully, and faint from loss of blood, she requested them to strangle the animal. They accordingly passed a cord round the dog's neck, and removing his collar, prepared to effect the operation; but he tugged so violently at the cord that he broke it, and rushed towards the room into which the lady had been conveyed. The door was closed on him, and he tried to force it open, but failed. On this, barking furiously, he rushed towards the people, who remained in the court-yard; but they were able to escape by the door, and to close it. The comissary of police, who had been sent for, now arrived, accompanied by some gendarmes, and he made them kill the animal. Medical assistance having been obtained for the unfortunate lady, it was found that she was in a fearful state. The dog was, after death, examined by a veterinary surgeon, and he declared that he was neither mad nor labouring under any malady. He further declared that, in his belief, the animal must have had a sort of instinctive hatred of his mistress, and must have been driven to fury by her beating him.

Mr. Richardson gives the following interesting account of a Newfoundland dog, which belonged to a gentleman in Eifeshire, and which was alike remarkable for its tractability and its trustworthiness. At two other points, distant about a mile from each other, and at the same distance from this gentleman's mansion, there were two other dogs, of great power, but of less tractable breeds than the Newfoundland. One of these was a large mastiff, kept as a watch-dog, by a farmer; and the other a staunch bulldog, that kept guard over the parish mill. As each of these three was lord-ascendant of all animals at his master's residence, they all had a good deal of aristocratic pride and pugnacity; so that two of them seldom met without attempting to settle their respective dignities by a wager of battle.

The Newfoundland was of some service in other domestic arrangements, besides his guardianship of the house; for every forenoon he was sent to the baker's shop in the village, about half a mile distant, with a towel containing money in the corner, and he returned with the value of the money in bread. There were many useless and not over-civil curs in the village; but, on ordinary occasions, the haughty Newfoundland treated this ignoble race in that contemptuous style in which great dogs are wont to treat little ones. When the dog returned from the baker's shop he used to be regularly served with his dinner, and he went peaceably on house-duty for the rest of the day.

One day, however, he returned with his coat dirtied, and his ears scratched; having been subjected to a combined attack of the curs, while he had charge of his towel and bread, and could not defend himself. Instead of waiting for his dinner as usual, he laid down his charge somewhat sulky, and marched off; and, upon looking after him, it was observed that he was crossing the intervening hollow in a straight line for the house of the farmer, or
rather on an embassy to the farmer's mastiff. The farmer's people observed this unusual visit; and they were induced to notice it from its being a meeting of peace between those who had habitually been belligerents. After some intercourse, of which no interpretation could be given, the two set off together in the direction of the mill; and, having arrived there, they, in brief space, engaged the miller's bulldog as an ally.

The straight road to the village where the indignity had been offered to the Newfoundland dog, passed immediately in front of that dog's master's house; but there was a more private and circuitous road by the back of the mill. The three took this road, reached the village, scoured it in great wrath, putting to the tooth every cur they could get sight of; and having taken their revenge, and washed themselves in a ditch, they returned, each dog to the abode of his master; and when any two of them happened to meet afterwards, they displayed the same pugnacity as they had done previous to this joint expedition.

It would seem that in this case there was a mere momentary concert for the accomplishment of one object among three dogs differing considerably in their habits; and that when this momentary purpose was accomplished, the wonted animosity of the three returned, and they fought as readily with each other as ever. But it does not appear that all casual, or apparently casual, interferences of dogs, for the benefit of each other, pass off in this momentary way; for there is another well-authenticated anecdote of two dogs, at Donaghadee, in which the instinctive daring of the one on behalf of the other, caused a friendship, and, as it would seem, a kind of mourning for the dead, after one of them had paid the debt of nature. This happened while the government harbour, or pier, for the packets at Donaghadee was in the course of building, and it occurred in the sight of several witnesses. The one dog in this case also was a Newfoundland, and the other was a mastiff. They were both powerful dogs; and, though each was good-natured, when alone, they were very much in the habit of fighting when they met. One day they had a fierce and prolonged battle on the pier, from the point of which they both fell into the sea; and, as the pier was long and steep, they had no means of escape but by swimming a considerable distance. Throwing water upon fighting-dogs is an approved means of putting an end to their hostilities; and it is natural to suppose that the same effect would take place from two combatants of the same species tumbling themselves into the sea. Accordingly, each began to make for the land as he best could. The Newfoundland, being an excellent swimmer, very speedily gained the pier, on which he stood shaking himself; but, at the same time, watching the motions of his former antagonist, which, being no swimmer, was struggling exhausted in the water, and just about to sink. In dashed the Newfoundland dog, took the other gently by the collar, kept his head above water, and brought him safely on shore. There was a peculiar kind of recognition between the two animals after this. They never fought again; they were always together; and when the Newfoundland dog was accidentally killed by the passage of a stone wagon over him, the other languished, and evidently lamented for a long time.

The care of the dog in directing the steps of the blind, is highly deserving of notice. There are few persons who have not seen some of these unfortunate objects thus guided along through the winding streets of a town or city, to the spot where they are to supplicate charity of passengers. In the evening the dog safely conducts his master back, and receives, as the reward of its services, that scanty pittance which wretchedness can bestow. Mr. Ray, in his Synopsi of Quadrupeds, informs us of a blind beggar who was thus led through the streets of Rome by a middle-sized dog, which, besides leading his master in such a manner as to protect him from all danger, learned to distinguish both the streets and houses where he was accustomed to receive alms twice or thrice a week. Whenever the animal came to any one of these streets, with which he was well acquainted, he would not leave it till a call had been made at every house where his master was usually successful in his petitions. When the beggar began to ask alms, the dog lay down to rest; but the man was no sooner served or refused, than the dog rose spontaneously, and without either order or sign, proceeded to the other houses where the beggar generally received some gratuity. "I
observed," says he, "not without pleasure and surprise, that when a halfpenny was thrown from a window, such were the sagacity and the attention of this dog, that he went about in quest of it, took it from the ground with his mouth, and put it into the blind man's hat. Even when bread was thrown down, the animal would not taste it unless he received it from the hand of his master."

Dogs can be taught to go to market with money, to repair to a known shop, and carry home provisions in safety. Daniel speaks of a person who lived at a turnpike-house about a mile from Stratford-on-Avon, who had a dog trained to go to a neighbouring town for any articles of grocery that he wanted. A note mentioning these was tied round his neck, and in the same manner the articles were fastened. In these errands the commodities were always brought safe to his master.

Smellie, whom Lord Brougham compliments in his admirable work on Instinct and Science, tells us, in his Philosophy of Natural History, that a grocer in Edinburgh had a dog, which, for some time, amused and astonished the people in the neighbourhood. A man who went through the streets ringing a bell and selling penny pies, happened one day to treat this dog with a pie. The next time he heard the pieman's bell he ran to him with impetuosity, seized him by the coat, and would not suffer him to pass. The pieman, who understood what the animal wanted, showed him a penny, and pointed to his master, who stood at the street-door, and saw what was going on. The dog immediately supplicated his master by many humble gestures and looks. The master put a penny into the dog's mouth, which he instantly delivered to the pieman, and received his pie. This traffic between the pieman and the grocer's dog continued to be daily practised for many months.

On the authority of Dibdin, we quote the following from his Observations in a Tour through England. At a convent in France, twenty paupers were served with a dinner at a certain hour every day. A dog belonging to the convent did not fail to be present at this regale, to receive the odds and ends which were now and then thrown down to him. The guests, however, were poor and hungry, and, of course, not very wasteful: so that their pensioner did little more than scent the feast of which he would fain have partaken. The portions were served by a person, at the ringing of a bell, and delivered out by means of what, in religious houses, is called a tour; which is a machine like the section of a cask, that, by turning round upon a pivot, exhibits whatever is placed on the concave side, without discovering the person who moves it. One day this dog, who had only received a few scraps, waited till the paupers were all gone, took the rope in his mouth, and rang the bell. His stratagem succeeded. He repeated it the next day with the same good fortune. At length the cook, finding that twenty-one portions were given out instead of twenty, was determined to discover the trick: in doing which he had no great difficulty; for, lying *perdu*, and noticing the paupers as they came in great regularity for their different portions, and that there was no intruder except the dog, he began to suspect the real truth; which he was confirmed in when he saw him wait with great deliberation till the visitors were all gone, and then pull the bell. The matter was related to the community; and, to reward him for his ingenuity, he was permitted to ring the bell every day for his dinner, when a mess of broken victuals was purposely served out to him.

In Vol. III. of the Annual Register, we find it stated, that "while a man of the name of Richardson, a waterman, near Hammersmith, was sleeping in his vessel, she broke from her moorings, and was carried by the tide under a west-country barge. Fortunately for the man, his dog happened to be with him; and the sagacious animal awakened him by pawing his face, and pulling the collar of his coat, at the instant the boat was filling with water. He seized the opportunity, and thus saved himself from otherwise inevitable death."

About the end of the last century, a person went to a house in Deptford, to take lodgings, under pretence that he had just arrived from the West Indies. After having agreed on the terms he was to pay, he said he should send his trunk that night, and come himself the next day. About nine o'clock in the evening, the trunk was brought by two porters, and was carried into his bed-room. Just as the family were going to bed, their little house-
ANECDOTES.

THE DOG, AND ITS VARIETIES; [BUFFON.

...dog, deserting his usual station in the shop, placed himself close to the chamber-door where the chest was deposited, and kept up an incessant barking. The moment the chamber-door was opened, the dog flew to the chest, against which it scratched and barked with redoubled fury. They attempted to get the animal out of the room, but in vain. Calling in some neighbours, and making them eye-witnesses of the circumstance, they began to move the trunk about; when they immediately discovered that it contained something that was alive. Suspicion becoming very strong, they were induced to force it open; when, to their utter astonishment, they found in it their new lodger, who had had himself thus conveyed into the house with the intention of robbing it.

In the Life of James Sackington, it is stated that Mr. C. Hughes, a son of Thespis, had a wig which generally hung on a peg in one of his rooms. He one day lent the wig to a brother player, and, some time after, called on him. Mr. Hughes had his dog with him, and the man happened to have the borrowed wig on his head. Mr. Hughes stayed a little while with his friend; but, when he left him, the dog remained behind; for some time he stood, looking full in the man's face; then making a sudden spring, leaped on his shoulders, seized the wig, and ran off with it as fast as he could; and, when he reached home, he endeavoured, by jumping, to hang it up in its usual place. The same dog was one afternoon passing through a field in the environs of Dartmouth, where a washerwoman had hung out her linen to dry. He stopped, and surveyed one particular shirt with attention; then seizing it, he dragged it away through the dirt to his master, whose shirt it proved to be.

Some nations are partial to the dog as food. In some of the South Sea islands dogs are fattened with vegetables, which the natives savagely cram down their throats when they will voluntarily eat no more. They become exceedingly fat; and are allowed, by Europeans who have overcome their prejudices, to be very palatable. They are killed by strangling; and the extravasated blood is preserved in cocoa-nut shells, and baked for the table. The negroes of the coast of Guinea are so partial to these animals as food, that they frequently give considerable prices for them; a large sheep for a dog was, at one time, a common article of exchange. Even the ancients esteemed a young and fat dog to be excellent eating. Hippocrates ranks it with mutton or pork. The Romans admired sucking whelpes, esteeming them a supper in which even the gods delighted.

When Lieutenant Fremont was at Fort Lamarie, on the Platte—a station of the American Fur Company—the Indians in the neighbourhood gave him an invitation to a feast of honour—a dog feast. "The women and children," says the lieutenant, "were sitting outside the lodge, and we took our seats on buffalo robes spread around. The dog was in a large pot over the fire, in the middle of the lodge, and, immediately on our arrival, was dished up in large wooden bowls, one of which was handed to each. The flesh appeared very glutinous, with something of the flavour and appearance of mutton. Feeling something move behind me, I looked round, and found that I had taken my seat among a litter of fat young puppies. Had I been nice in such matters, the prejudices of civilisation might have interfered with my tranquillity; but, fortunately, I am not of delicate nerves, and continued quietly to empty my platter."

Buffon has bequeathed us an excellent description of the dog, the substance of which is here given.

"The dog," he says, "independently of the beauty of his form, his vivacity, force, and swiftness, is possessed of all those internal qualifications that can conciliate the affections of man, and make the tyrant a protector. A natural share of courage, an angry and ferocious disposition, renders the dog, in its savage state, a formidable enemy to all other animals: but these readily give way to very different qualities in the domestic dog, whose only ambition seems to please: he is seen to crouching along, to lay his force, his courage, and all his useful talents at the feet of his master; he waits his orders, to which he pays implicit obedience; he consults his looks, and a single glance is sufficient to put him in motion; he is more faithful even than the most boasted among men; he is constant in his affections, friendly without interest, and grateful for the slightest favours; much more mindful of benefits received than injuries..."
offered, he is not driven off by unkindness; he still continues humble, submissive, and imploring; his only hope to be serviceable, his only terror to displease; he licks the hand that has been just lifted to strike him, and at last disarms resentment by submissivo perseverance.

"More docile than man, more obedient than any other animal, he is not only instructed in a short time, but he also conforms to the dispositions and the manners of those who command him. He takes his tone from the house he inhabits; like the rest of the domestics, he is disdainful among the proud, and churlish among clowns. Always assiduous in serving his master, and only a friend to his friends, he is indifferent to all the rest, and declares himself openly against such as seem dependent like himself. He knows a beggar by his clothes, by his voice, or his gestures, and forbids his approach. When at night the guard of the house is committed to his care, he seems proud of the charge; he continues a watchful sentinel; he goes his rounds, scents strangers at a distance, and gives them warning of his being on duty. If they attempt to break in upon his territories, he becomes more fierce, flies at them, threatens, fights, and either conquers alone, or alarms those who have most interest in coming to his assistance. However, when he has conquered, he quickly reposes upon the spoil, and abstains from what he has deterred others from abusing; giving thus at once a lesson of courage, temperance, and fidelity.

"From hence we see of what importance this animal is to us in a state of nature. Supposing, for a moment, that this species had not existed, how could man, without the assistance of the dog, have been able to conquer, tame, and reduce to servitude every other animal? How could he discover, trace, and destroy those that were noxious to him? In order to be secure, and become master of all animated nature, it was necessary for him to begin by making a friend of part of them; to attach such of them to himself, by kindness and caresses, as seemed fittest for obedience and active pursuit. Thus the first art employed by man was in conciliating the favour of the dog; and the fruits of this art was the conquest and peaceful possession of the earth.

"The generality of animals have greater agility, greater swiftness, and more formidable arms, from nature, than man; their senses, and particularly that of smelling, are far more perfect: and having gained, therefore, a new assistant, particularly one whose scent is so exquisite as that of the dog, was the gaining a new sense, a new faculty, which before was wanting. The machines and instruments which we have imagined for perfecting the rest of the senses, do not approach to that already prepared by nature, by which we are enabled to find out every animal though unseen, and thus destroy the noxious, and use the serviceable.

"The dog, thus useful in itself, taken into a participation of empire, exerts a degree of superiority over all animals that require human protection. The flock and the herd obey his voice more readily even than that of the shepherd or the herdsman; he conducts them, guards them, keeps them from capriciously seeking danger; and their enemies he considers as his own. Nor is he less useful in the pursuit; when the sound of the horn, or the voice of the huntsman, calls him to the field, he testifies his pleasure by every little art, and pursues with perseverance those animals which, when taken, he must not expect to divide. The desire of hunting is, indeed, natural to him, as well as to his master, since war and the chase are the only employ of savages. All animals that live upon flesh hunt by nature. The lion and the tiger, whose force is so great that they are sure to conquer, hunt alone, and without art. The wolf, the fox, and the wild dog, hunt in packs, assist each other, and divide the spoil. But, when education has perfected this talent in the domestic dog—when he has been taught by man to repress his ardour, to measure his motions, and not to exhaust his force by too sudden an exertion of it, he then hunts with method, and always with success."
CHAPTER III.

VARIETIES OF THE DOG—WILD AND HALF-WILD.

If we pass from dogs confessedly wild to those which are half-wild, only semi-domesticated, the Dingo, or Australian dog, is one of the most remarkable and best known. Of the origin of this dog, and of the circumstances connected with its introduction into Australia, we are totally ignorant. We know that wild packs exist in the remoter districts, and are the scourge of the country, preying on the native kangaroo, and making havoc among the flocks and herds of the European settlers. So wolf-like are these dogs in general form—that they are specifically distinct from the wolf—that the first navigators who touched at New Holland scarcely recognised them as dogs. Dampier, in the account of his voyage performed in 1699, states that his men saw two or three beasts like hungry wolves; and the similarity is, to a certain degree, very striking. The domestic breed—if domestic it can be called—in all respects resembles those which are completely emancipated.

THE DINGO.

The Dingo, called Warragal by the natives, is about as large as a harrier; its body is firmly built, its limbs muscular; its head is broad between the ears, and its muzzle is acute; the neck is thick and powerful; the ears are short, pointed, and erect; its tail, which is rather long, is somewhat bushy and pendulous, or, at most, raised only horizontally. The general colour is sandy red; the eyes are rather small and oblique, which is one of the diagnosties of a low degree of culture, and is never seen in what are termed high-bred animals.

The agility and muscular powers of the Dingo are extraordinary; and its cunning and ferocity are as much so. It never barks, but howls loudly; and is said never to discover a feeling of pleasure by wagging the tail. The natural habits of one which was brought to this country in about the sixth week of its age, was closely watched. On its being put into a room, it immediately skulked into the darkest corner, and there crouching, eyed those in its presence with looks of great distrust and aversion: as soon as left to itself, it commenced the most melancholy howling, which ceased on any person's entrance. This, for some days, was its constant practice; and, when placed in a kennel, the greater part of the day was thus passed. It grew up strong and healthy, and gradually became reconciled to those from whom it was accustomed to receive food, but was shy towards others, retreating into its kennel at their approach. It never barked, nor, like other dogs, gave notice of the approach of strangers, and therefore, as a guard, was perfectly useless. A great part of the day was spent in howling, and that so loudly as to be heard at the distance of more than half a mile. When the moon rose brightly, it would sit and utter, for hours, its wild lamentations, not a little to the annoyance of the neighbourhood. With all its shyness, it was, at the same time, savage, but would never make an open attack. Several times it snapped at persons who happened to be walking within its reach, but only when their backs were turned, and it immediately retreated again into its kennel. So great was its strength, that though encumbered by a heavy chain, it leaped a wall of considerable height, and was not secured without difficulty.

This animal is a great pest to the Australian settler, and is remarkably tenacious of life. It is also a very obstinate fighter. Instances are related of its sustaining a combat with four or five stout hounds, and ultimately getting away from them. Very few dogs can kill a Dingo single-handed. Like the wolf, it fights in silence, and utters no cry of pain; but, like that grim felon, dies as hard as it has lived. The following instances of its tenacity of life are given by Mr. George Bennett, in his Wanderings in New South Wales:

"One had been beaten so severely that it was supposed all its bones were broken, and it was left for dead. After the person had walked some distance, upon accidentally looking back,
his surprise was much excited by seeing the Dingo rise, shake himself, and march into the bush, evading all pursuit. One, supposed dead, was brought into a hut, for the purpose of undergoing decortication: at the commencement of the skinning process upon the face, the only perceptible movement was a slight quivering of the lips, which was regarded at the time as merely muscular irritability. The man, after skinning a very small portion, left the hut to sharpen his knife, and, on returning, found the animal sitting up, with the flayed integument hanging over on one side of the face.

In New Zealand there has been found an apparently feral dog, called by the natives "Kaearahe." Regarding this animal there is a tradition, which says, that he was given to them some centuries ago by certain divinities who visited their shores. In appearance, this dog closely resembles the "Dingo," but he seems to have been partially domesticated.

There is a small dog domesticated on the banks of the Niger, very nearly resembling the Dingo in form, but on a much more diminutive and lighter scale, and with a longer muzzle in proportion. Its general colour is reddish.

THE DHOLE.—CANIS PRIMAÆVUS.

The Dhole is a native of India, over which peninsula it extends in great numbers, and bears different names in different parts. It was originally described by Mr. Hodgson as the Búánsú, and by him given the title of Canis primaævus—original, or primeval dog—as, in his opinion, it was the origin of the domestic dog. The locality of the dog to which we have already alluded, was Nepal, the eastern and western limits of its range being the Sutlej and the Burhampoora.

In 1831, Colonel Sykes described a wild dog from the Mahattas, which he calls the wild dog of the Deccan; to which we have also already alluded, and which would seem to be identical with Mr. Hodgson's dog.

The Dhole, Búánsú, or Kolsun—for these names are synonymous—is about the size of a small wolf, but is much more powerfully built; its limbs, in particular, being remarkably large-boned and muscular, in proportion to its size. Its ears are large, and rounded at the tips; the muzzle moderately pointed; the tail very bushy; and its colour a sandy red, or buff.

"In habits, these dogs present all the characteristics of ferocious beasts of prey. They prowl by night and by day indiscriminately, and hunt in packs of from ten to sixty. While in pursuit they utter a peculiar yelp; and it is on scent, and not on sight, that they mainly depend for success. Their speed, however, is considerable, and their savage courage and endurance render them a terror to the most formidable rangers of the wilds. Bishop Heber says of this dog—'They are larger and stronger than the fox, which in form and fur they resemble. They hunt in packs, give tongue like dogs, and possess an exquisite scent. They make, of course, tremendous havoc among the game in these raids; but the mischief is said to be repaired by destroying wild beasts.' The panther, the wild bull, the tiger, the elephant, fall an easy prey before a pack of dholes. On they sweep, coming upon their game with the force of an avalanche, and overwhelming their victim in a living torrent. The hunted animal may, indeed, kill many of his enemies, but he has little time afforded him for exertion or display of prowess; for the dead or wounded are hardly missed ere others have rushed into their places.—The wild dog of China has a great resemblance to the Dhole but is usually less in size, and its ears are smaller and more pointed; its colour is that of a lively bay."

THE DEEB OF EGYPT.

The Deeb of Egypt chiefly inhabits Abyssinia and Nubia, and is a very ancient dog. Some naturalists have considered it as the original type; but this of course is a point which it is impossible to settle. It has erect ears; semi-pendulous lips; muzzle rather blunt at the point; tail hairy and short; and its colour is that of a dirty white, intermixed with black and buff; its height is about eighteen inches.

SOUTH AMERICAN RACES.

Among the wild races of dogs, or rather of dogs become wild, to which Buffon alludes, are those of South America and the West Indian Islands, confessedly sprung from a European stock, left or lost by the early settlers in the vast plains. These have given origin to an unreclaimed race. Azara states that these dogs are
called Yagoua in Paraguay, where they are very common, and dwell in caves. They formerly abounded in Hayti, Cuba, and all the Caribbean islands; but are now extirpated there. Mr. Darwin alludes to wild dogs in Banda Oriental as attacking sheep. According to Oexmelin these dogs resemble the greyhound; but others more accurately describe them as having the head flat and elongated, the muzzle sharp, the body slender, and the general aspect wild and savage. They are strong and active, and hunt their prey in packs.

It would appear, however, that the Europeans, on their arrival, found native dogs both in the Caribbean Islands and in Peru. "Those belonging to the savages of the Antilles," says Buffon, "had the head and ears very long, and resembled a fox in appearance." He also adds that the Indians of Peru had a large and a smaller kind of dog, which they named Alco, and that those of the Isthmus were ugly, with rough, long hair, and erect ears.

With respect to the Alco of Peru and Mexico, nothing more is known about it than what Dampier and Fernandez mention. The latter describes two breeds—viz., the fat Alco, or Michucaneus, called by the natives Ytecuinte porzoalii, and the broad-footed Alco, or Techihi. Both were small, some of the latter race not much exceeding a guinea-pig in size. The head was small, the back arched, the body thick, the ears pendulous, and the tail short. An individual, probably of this race, was brought to this country from the neighbourhood of Mexico, by Mr. Bullock; it was white, variegated with black and reddish-yellow. This specimen was procured in the mountains of Durango, where it bore the name of Acoletto. It died in a few days, and its stuffed skin formed part of a collection exhibited in Piccadilly, being placed under a glass with a huge bull-frog, which equalled it in size. Dogs resembling the Alco were seen as early as 1492, in several of the West Indian Islands, by Columbus; and were also found in Martinique and Guadaloupe, in 1635, by French navigators, who describe them as resembling the little Turkish, or Barbary dogs, without hair; adding, that they were eaten by the inhabitants. All trace of them is now lost.

The probability is that these Alco dogs were not indigenes to the soil, either in the islands or on the continent of Peru; but were brought by some of the tribes by whom South America was populated. The breed might have been introduced by that strange people (of Malay descent?) who founded the Peruvian and Mexican empires. In the South Sea Islands, dogs of a similar race exist, which are fed on vegetable food, and eaten, as were the Alco dogs in South America.

African Dogs.

Wild dogs exist in Congo, Guinea, and other parts of Africa, hunting in packs, and dwelling in caves or burrows. Clapperton met with them in the country beyond Timbuctoo. In the island of Teneriffe, a large wolfish breed of dogs is domesticated, and valued for the chase.

Major Denham used African hounds in Africa for hunting the gazelle; in the chase of which, their exquisite scent and extraordinary speed were displayed to great advantage. They would frequently quit the line of scent for the purpose of taking a direct, instead of a circuitous course—sportsmen call this cutting off a double—and recover the scent again with wonderful facility. These beautiful hounds were brought to England, and consigned to the Tower menagerie; where, shut up in a close den, they were doubtless miserable. Instead of exerting their energies in pursuit of the antelope on the plains of Africa, here they were prisoners, with no means of escape, and with no room or opportunity for the exercise of their powers and instincts. They were not, however, of a wild breed; in symmetry and action they were perfect models; and in temper were gentle, excepting that confinement rendered the female irritable.

The Cape hunting-dog is a daring and fero-cious animal; and as the Dingo is in Australia, so it is one of the pests of Southern Africa. It is a complete dog, or Canis, in the form of the skull and the characters of the teeth; it has, however, as in the hyaenas, only four toes on the anterior feet, and the same on the feet behind. In figure it is tall, lightly built, but muscular and well proportioned; the limbs are long, the ears large and erect, the jaws powerful, and the teeth strong. Its aspect is wild and fierce, and its disposition treacherous. The fur is close and of a sandy yellow, irregularly.
ESQUIMAUX DOGS.] FOR MOUNTAIN, FIELD, AND FARM. [ESQUIMAUX DOGS.

clouded and blotched with black and a little white. The tail is somewhat bushy, and of moderate length. The colour is subject to variation.

Wild, fleet and savage, this species hunts in packs mostly during the night, but frequently in the day; and so fleet is it that few animals can out-distance its speed. It often commits extensive ravages on the flocks and herds of the farmer, though it seldom attacks horned cattle openly, but steals on them while asleep, and bites off their tails, even at the root, with one snap—a fact which the wide gape and vast power of its jaws enables it to do with ease.

Mr. Burchell, on his return from Africa, brought a living individual to England, which retained during life all its native ferocity.

It is the general opinion of naturalists, that this species is an intermediate link in the chain of the carnivorina, uniting the canine group to the hyaenas. Indeed, in some points of general aspect, and in the number of the toes, the approximation of this dog to the latter animals is so marked, that Mr. Burchell regarded it as a hyæna; and, as such, Temminck described it, under the title of hyæna pietæ, though he afterwards assigned it to the genus canis. The name of hyæna-dog has also been conferred upon it.

In size, the Cape hunting-dog (Wilde Houden of the Dutch colonists) is as large as a pointer or hound, but higher on the limbs in proportion to the bulk of the body. We are not aware that any serious attempts have been made to domesticate it.

ESQUIMAUX DOGS.

Dogs which, in their aspect and physiognomy, retain a marked air of wildness, as indicated by the sharpness of the muzzle, the erect or semi-erect position of the ears, and the oblique direction of the eye—giving an air of cunning and distrust to the countenance—are found in the Esquimaux race. In general aspect, this dog—Canis familiaris, var. borealis—so closely resembles the wolf of its native regions, that, when seen at a little distance, it is not easy to distinguish between them; so much so, indeed, is this the case, that Sir Edward Parry's party, during their second voyage, forbore to fire upon a pack of thirteen wolves, which had closely followed some Esquimaux, lest they should commit an irreparable injury upon these poor people by destroying their faithful and powerful allies.

In both the Esquimaux dog and grey wolf, the fur is deep and thick; both have the same erect ears, the same breadth of skull between them, and the same, or nearly the same, sharpness of muzzle. In addition, we may state that, in its native wilds at least, the voice of this dog is not a bark, but a long melancholy howl.

In the dog, however, the tail is more bushy than in the wolf, and is carried in a graceful curve over the back; while in the wolf it hangs down between the legs. It is further to be remarked, that the antipathy of the Esquimaux dog to the wolf is inveterate. He not only regards the wolf as an enemy, but fears it; and though he will attack the bear with undaunted energy, he never, unless impelled by necessity, ventures to assault the wolf. Often, indeed, he falls a sacrifice to this beast of prey, and is carried off even in sight of his owners.

To the Esquimaux their dogs are of the greatest importance. It is to them that they look for assistance in the chase of the seal, the bear, and the reindeer; for carrying burdens, and for drawing them on sledges over the trackless snow of their dreary plains. In summer, a single dog carries a weight of thirty pounds in attending his master in the pursuit of game; and in winter, six or seven dogs, yoked to a heavy sledge, with five or six persons, or a load of eight or ten hundredweight, will perform a journey of forty or fifty miles a day. On good roads they will travel this distance at the rate of eight miles an hour for several hours together; but on untrodden snow, twenty-five or thirty miles would be a fair day's journey. The same number of dogs, well fed, with a weight of only five or six hundred pounds, that of the sledge included, are almost unmanageable, and, on a smooth road, will go at the rate of ten miles an hour. While thus travelling, should they scent a reindeer, even a quarter of a mile distant, they gallop off furiously in the direction of the scent, and soon bring the game within reach of the arrow of the hunter. So acute, indeed, is their sense of smell, that they will discover a seal-hole by it entirely, at a very great distance.

The average height of the Esquimaux dog is one foot ten inches; generally the colour is
white, with something of a yellow tinge; but some are brindled, some black and white, and some black.

THE MACKENZIE RIVER DOG.

If the Esquimaux dog resembles the grey wolf of North America, equally does the Hare Indian’s or Mackenzie River dog resemble the fox. This dog (Canis familiaris, var. lagopus) is characterised by a narrow, elongated, and pointed muzzle; by erect, sharp ears, and by a bushy tail, not carried erect, but only slightly curved upwards, and by the general slenderness of the form. The hair is fine and silky, thickening in winter, when it becomes white, or nearly so; but in summer it is marked by patches of greyish black or slate-grey, intermingled with shades of brown. So nearly does this dog resemble the arctic fox of the regions where it is found, that they have been considered merely as varieties of each other, one being of the wild, the other of the domesticated race. The Hare Indian’s dog is never known to bark in its native country; and the beautiful pair brought to England by Sir John Franklin and Dr. Richardson, never acquired this canine language. One born in the Zoological Gardens, however (the pair in question having been presented to the Society), readily learned it, and made his voice sound as loudly as any European dog of his size and age.

This variety is of great value to the natives of the bleak and dreary realms where the moose and the reindeer are objects of the chase. Though it has not strength fitting it for pulling down such game, yet its broad feet and light make, enable it to run over the snow without sinking, if the slightest crust be formed on it, and thus easily to overtake the moose and the reindeer, and keep them at bay until the hunters come up. In the fox the pupil of the eye is oblong; in the dog, circular; but, independently of this, it is, to say the least, highly improbable that this intelligent dog is specifically identical with the arctic fox. If, for the sake of argument, however, we grant that it is, as some contend, and also that the Esquimaux dog is identical with the wolf, other dogs also being reclaimed wolves, we are involved in a dilemma; for we must then admit that the wolf and fox will breed together, and produce a fertile offspring, which those who contend for the wolffish origin of the dog by no means will allow to be possible.

THE POMERANIAN, OR WOLF-DOG.

The Pomeranian, or wolf-dog (chien-loup), and the Siberian dog, the Lapland dog, and the Iceland dog, of Buffon, appear to be closely related to the Esquimaux dog. Buffon regards them as varieties of the shepherd’s dog, which he considers to be that which, of all, is nearest the primitive type, since, as he observes, in all inhabited countries, whether men be partially savage or civilised, dogs resembling this more than any other are spread; and he attributes its preservation to its utility, and its being abandoned to the peasantry charged with the care of flocks. If, however, great cerebral development and intelligence are to be received as tests of cultivation, we should be inclined to regard the shepherd’s dog as one of the most remote from the original wild type, sharp and pointed as are its nose and ears. The forehead of the Pomeranian dog rises; the top of the head is arched and broad between the ears, and the hair is long, and sometimes matted. This dog is of middle size, but light, active, and strong.

Mr. Youatt, in his treatise on The Dog, says, the Pomeranian, or “wolf-dog, is no longer a native of Britain, because his services are not required there; but he is useful, in various parts of the continent, in the protection of the sheep from the attacks of the wolf. A pair of these dogs was brought to the Zoological Society of London, in 1833, and there long remained an ornament to the gardens. They appeared to possess a considerable degree of strength, but to be too gentle to contend with so powerful and ferocious an animal as the wolf. They were mostly covered with white or grey, or, occasionally, black hair, short on the head, ears, and feet, but long and silvery on the body and tail. The forehead is elevated, and the muzzle lengthened, and clothed with short hair. The attachment of this dog to his master and the flock is very great; and he has not lost a particle of his sagacity; but, where wolves are common, is still used as a sheepdog.”
CHAPTER IV.

THE DOMESTIC DOG.—PASTORAL DOGS AND TERRIERS.

"Domestication," says Mr. Blaine, "proves a powerful agent in promoting various changes from the original form, characters, and habits of quadrupeds. By its agency they are enlarged to monstrosities, or diminished to pigrpies; it even operates in the increase or decrease of the organs themselves. A breed of tailless cats and curtailed dogs has been perpetuated. The horns of cattle, essential as they are to the animals in their wild state, are dispensed with when the animals themselves are taken under the protection of man; and polled breeds of oxen and sheep are now common among us. We have an instance of the former in the Galloway bull. Neither need we wonder at these changes, great as they are, when we consider how numerous and how potent are the agents which the artifice and experience of man enable him to employ. Indeed, man himself, though apparently a free agent, is no longer the same being that he was when he lived in a pure state of nature. His external characters are much changed; while internally he is subjected to morbid alterations unknown to savages. Neither is it to be wondered at that the controlling power of man should be so influential, extending as it does over every important circumstance connected with the beasts around him. Man regulates at his pleasure the quantity and quality of their food; he also governs all their motions, and restrains their exercise to close confinement, or increases it to great and continued exertions. Even the temperature they reside in is raised or lowered at the will of the owner; and still further and more important restraint is put on them by regulating their sexual intercourse, which insures the perpetuation of almost any desired form, by allowing the propagation only between such individuals as approach the nearest thereto. In other instances, an accidental variation which may have occurred, or a singular deformity, has been seized on and propagated by future similar selections, until it became permanent, and then it constitutes a breed. To something of this kind we owe the wry-legged terriers; and it is probable, also, that a crooked mastiff offered the foundation for the bulldog."

THE SCOTCH COLLEY.

One of the theories to which we have alluded is that of ascribing the original dog to the pastoral or shepherd’s breed, known in Scotland, and the north of England, as the Colley. However this may be, this species is certainly one of the most sagacious of all descriptions of dogs. Anecdotes, well authenticated, of his performances, would of themselves make a bulky volume. In the structure of the feet of this species of dog, there is a peculiarity which has attracted the observation of the naturalist. Mr. Richardson describes it as consisting of a greater or smaller number of supplemental toes or appendages, called "dew-claws," and situated at the hinder part of the foot. The pointer, the spaniel, and all dogs which prey upon ground game, without running it down in the chase, are possessed of these appendages, which evince, in a striking manner, the admirable care which Nature takes to adapt every animal to the duties which it has to perform. "They are soft and pendent," says Mr. Richardson, "but do not act by means of muscles, like the toes properly so called, but are a sort of fringe to the back part of the foot. In walking on hard surfaces they are of no use; and as they are liable to be torn and lacerated in beating among bushes, and thus to cripple the animals—for wounds in the feet of dogs are more injurious to them than in any other part of their bodies—they are cut off in sporting dogs when very young; but in shepherds’ dogs, and in pastoral dogs generally, they are allowed to remain; and in the hill pastures especially, which are interspersed with bogs, and places between the hummocks of grass which consist of soft and sludgy peat, these dew-claws, by spreading out to their whole length by a little pressure, greatly extend the
surface of the foot, and thus enable it to bear up the animal in situations where it otherwise would sink, in the same manner as people furnished with snow shoes can walk over snowy surfaces, in which, if they had not these means of protection, they would sink knee-deep. This peculiarity is found wanting in all the coursing dogs, and in all those which, in a state of nature, find their prey upon the firm ground.

When we think of the sportsman walking over, and the dew-clawed dog running over, such bogs as are above alluded to, what reflections does the mind conjure up! Who can guess the secrets of the peat bog? Who can divine all that is buried beneath that sable and partially heath-covered surface? Far, far down in its depths, and even beneath the thin soil of the moor, lies hidden many a secret of bygone days. Below the grim, ghastly surface, the waters, and the black remnants of countless plants, lie the sad memorials of ages unknown to the history of man. Huge trees stand upright, and their gigantic roots rest upon the crowns of still older forest giants! In the inverted oaks of Murten Moor, in Switzerland, many see the famous oak woods that Charlemagne caused to be cut down, now more than a thousand years ago. For centuries the moors have concealed, in their silent bosoms, the gigantic works of ancient Rome. Far in the deep, lie buried in stone, hatchets and flint arrow-heads of Frisians and Cheruski, by the side of the copper kettle and the iron helmet of the Roman soldier. The skeletons of ante-diluvian animals rest there peaceably by the corpses of ancient races with sandals on their feet, and skins of animals around their naked bodies. Hundreds of brave English horsemen, who sought an honourable death in the battle of Solway, were swallowed up, horse and man, by the insatiable moor. In years bygone, a Danish King Harold, called the Blue Tooth, allured with foul treachery a fair princess of Norway, Gunhildo, to Jutland. She came, and she vanished from the memory of man. History had forgotten her; tradition had even begun to fade; but the peat bog opened its long-closed lips, and accused, late, but loud, the bloody king, of this wicked deed. The poor princess was found far below the peat, strangled and tied to a post, where her merciless foe had buried her, as he thought, for ever, in the abyss.

THE COLLEY, OR SHEPHERD'S DOG.

Of the sagacity and faithfulness of the shepherd's dog many interesting narratives are current. It knows its master's flocks; it will single out a sheep under his direction, keep it separate, or disengage it again from the rest of the flock, should it regain or mingle with them; it will keep two flocks apart, and, should they become mixed, it will re-divide them. It will watch and defend them from strange dogs or foxes, and will drive them to any place required. It is, in fact, the shepherd's friend and assistant; it watches every look and every sign, is quick in apprehension, prompt in obedience, and pleased with its master's praise; and well does he who tends his flocks on the wide pastur-lands or mountain districts of our island, appreciate the services and fidelity of his attached ally.

Mr. Hogg, known by his poetical soubriquet of the "Ettrick Shepherd," has given us many anecdotes of the sagacity of this dog; and we ourselves, in the hill districts of Scotland, have seen many of them exhibit a degree of intelligence almost human.

He stands about twenty-one inches in height at the shoulder; is very gracefully shaped; ears half erect; muzzle pointed; coat long, but fine and silky; tail and hams fringed with hair; colour usually black and tan, or sandy yellow; but there are many black and white.

In England the species is larger, but, we think, scarcely so active, and certainly by no means so graceful, being destitute of tail. This apparent defect in the structure of the animal is not natural; but is the effect of what is termed "stringing," an operation performed when the animal is young, and which consists of pulling out the bone of the tail with the teeth. This causes the fleshy portion of the appendage to contract, until it becomes apparently nothing more than a mere tuft of hair. It is said that dogs thus denuded endure more fatigue than when in possession of their tails.

Both in Scotland and England the breed of the sheep-dogs is preserved with the greatest attention to purity. The Arab has scarcely greater affection for his horse than the Scottish shepherd has for his dog. As the one is the constant companion of the wanderer in the desert, so is the other the constant companion of the
flock-watcher of the mountains. In the points of size and strength, however, the Scotch and English breeds are much inferior to those of some other countries. In the Alps and the Pyrenees, for example, the breeds are much larger and stronger; whilst, in the neighbourhood of the Caucasian range, there is an equally large and powerful variety.

The "Colley" of France bears a strong resemblance to the English breed in form and size. His disposition is, also, similar; and he possesses all the attributes of the other. He likewise, in his puppyism, is denuded of that graceful appendage—the tail—a practice which we cannot help stigmatising as inhuman, and by no means counterbalanced by the additional benefits supposed to be derived from it by their masters.

Nearly allied to the "Colley" is the dog of the drover, somewhat larger, but equally sagacious. He would seem to be the produce of a cross with the lurcher. He has great courage and strength, and will attack the fiercest bullock, and hold him, if commanded so to do by his master.

The cur is a mongrel sprung from the Colley. He is a tantalising, barking, apparently spirited, but cowardly animal. He is the biter of the horses' heels, but the vigilant watch-dog of the humble dwelling of the cottager. His voice is always heard the moment an invader of the precincts of that tenement appears. The tail of the cur is mostly cut short; but Bewick says that many are whelped with short tails, which seem as if they had been cut, and these are called, in the North, "self-tailed dogs."

Though this writer thinks the cur-dog to be a true or permanent breed, it seems to us that it is a cross between the shepherd's dog and some other race, perhaps the terrier.

**TERRIERS.**

Supposing the shepherd's dog to be the representative of a small section of the domestic canine race, the next to which we may turn is that of the terriers. These are a very hardy race, full of courage and spirit, and will face anything, without the slightest indication of fear. They are a small breed of dogs, but have an amazing degree of strength, a sharp bite, and have, to a great extent, the power of "holding on" to whatever they get within the grasp of their teeth. The property for which they are most distinguished is for hunting up such animals as burrow under ground, pressing them from their earths, and then attacking them with the utmost fierceness and determination. We have seen some Scotch terriers fight until they were lacerated in the most dreadful manner; and even then they would not give up the contest, however unequal, and had to be lifted and taken away. They will even face a badger with the most resolute spirit. All wild animals they will attack indiscriminately, although, properly speaking, they are what are called vermin dogs. Rats, mice, weasels, polecats, and badgers, they will fall upon on the instant; hence their value in the country, where the stock of the farmer is so frequently a prey to some of these marauding animals. To the rat they are a most determined foe; and well that it is so, for the great fecundity of these noxious animals is one of the circumstances which renders them so formidable in their destructive propensities. "Go," says a writer, "into a barn or granary, where hundreds are living, and you shall not see one; go to a rick that may be one living mass within, and there shall not be one visible; or dive into a cellar that may be perfectly infested with them, rats you shall not see; no, not so much as a tip of a tail, unless it be that of a stray one 'popping across for a more safe retreat.' As men seldom see them, they seldom think of them. But this I say," continues the writer, "that if rats could, by any means, be made to live on the surface of the earth, instead of in holes and corners, and feed and run about the streets and fields in open day, like dogs and sheep, the whole nation would be horridly stricken; and ultimately there would not be a man, woman, or child able to brandish a stick, but would have a dog, stick, or gun for their destruction, wherever they met with them. These midnight marauders and common enemies of mankind, devour the food, to the starvation of our fellow-creatures." The writer does not altogether ignore the argument of the friends of the rat—that these vermin destroy in the sewers much matter that would otherwise give out poisonous gases. Sewer rats, he admits, are not the very worst of the race; but even they should be slain wherever they may be caught. But the rats of the cellar, the
warehouse, the barn, the rick-yard, the granary, and the corn-field, are the grand destroyers against which war by the terrier, the trap, and the ferret should be proclaimed.

Whilst the terrier is one of the best of rat-killers, he is also a good house-dog, sufficiently vigilant, and at all times ready to attack any one who, at an improper season, dares to disturb the quiet of the household. Mr. Richardson tells us that he knows a gentleman who had a very fine Scotch terrier, which not only cleared a large farm, and also the farm-yard, of all vermin, but acted as cattle-dog or sheep-dog, as occasion required. He used successfully to repel the inroads of a very powerful and fierce boar, which was wont to come in a furious and formidable manner; so much so, indeed, that he often threw the labourers in the field into the greatest alarm; but if Trap happened to get notice of the invasion, the boar, though very large (much in the shape of a wild boar, and of that brindled colour which indicates the nearest approach to that formidable animal), paid severely for his temerity. The dog, which had been trained to keep animals in their right places, but to kill nothing except game and vermin, made no direct attack on the life of the boar. He laid hold of him by the ear; and that hold he kept till the boar, though much stronger and far heavier than the dog, was so completely subdued, that Trap could lead him by the ear to his own place of abode. The dog had seldom occasion to take him half-way; but he used to watch his motions; and if the boar offered to return, the dog instantly went to meet him, and so punished his other ear, that there was no need for a second warning, at least during the next week.

One of the principal uses of the terrier, as a hunting dog, is to accompany the foxhounds; and, in cases where all the earths are not carefully stopped he is indispensable, because his assistance is necessary in unearthing Reynard.

THE SCOTCH TERRIER.

Of this breed there are three varieties; one of a sandy-red colour, standing about eighteen inches high, very strong, with short stout legs; he has a large head in proportion to his body; a somewhat pointed muzzle, and an acute scent; his ears are small, and his bite very sharp. This variety is very common, and may frequently be seen quietly sitting at the door-steps of many of the houses in the more quiet and respectable localities of London. They abound in Scotland, and are generally known as the "Highland Terrier." The hair is hard and wiry, frequently closely or thickly matted; and when intermixed, or marked with white or any other colour, it is a certain sign of impurity. The best are such as are of a russet, sandy, or black colour. They are extremely attached to their masters, and we think are very tenacious in memory. We, many years ago, possessed an impure specimen, which nevertheless was an excellent little dog; he either wandered or was stolen from us, in a place near Doune, in Stirlingshire; and several months afterwards we were told that such a dog was at a miller's, about twenty miles from where we were at that time. Neither the distance nor the uncertainty of its being our dog deterred us from setting out on foot (there were no conveyances in those days up to the hills) to ascertain the fact. Accordingly, we arrived at the miller's, and elevating our voice, heard "Pincher" reply from a small sort of granary, where he had been carefully detained. We soon had him at liberty; and we shall never forget the joy which he exhibited at our meeting. We walked immediately back; and, at the end of our journey, did not feel in the least tired, so happy were we at the recovery of our faithful and attacked little dog.

The other two varieties are those of the Pepper and Mustard kind, celebrated by Sir Walter Scott in Guy Mannering, and the variety which prevails in the Western Islands of Scotland. The first is low, long-backed, and short-legged; with wiry and curly hair, and a pretty long muzzle. The second is about the same size as the sandy-red coloured one, but with the hair much longer, and having a more flowing appearance.

Besides these there is the

SKYE TERRIER.

This valuable little dog takes its name from one of the Hebrides, or western islands, where it is found in the greatest perfection. It is longer in the body and lower in the legs than the Highland dog; covered with long, silky, and silvery-looking hair, and has its breasts and
legs of a light or palish tan colour. It is considered the second variety of the Scotch terrier, and is famous for the destruction of vermin. In Blackwood's Magazine, a real Skye terrier is thus described:—"A mouth, the roof whereof is dark as midnight; his glittering eyes are black as jet; his ears short; his legs none of the longest; but his body is. His tail is a triumph, when fairly spread out; and as for the strength with which it is attached to his body, you may hold him up by the aforesaid tail as long as you can—with one hand. Then his hair is pepper-and-salt in hue, long and curly, and—if I may so speak (though no one but myself and the family will know exactly what I mean by it)—with a kind of silken wiriness."

THE ENGLISH TERRIER.

This dog is commonly of a black and tan colour; and those of this tint are the best; but they are sometimes white. If black and tan, they should not present a speck of white; and if white, they should be entirely of that colour.

In conflict, the English terrier is as resolute as the Scotch; but he is less capable of supporting cold, and is not so fond of the water. What was the primitive stock of this breed we cannot say; but we should be inclined to concur in the opinion of Mr. Richardson, that his original is to be found in the rough, or Scotch breed. We are the more inclined to this opinion, as we have seen a pair of beautiful Skye terriers, with careful feeding and nursing, gradually become smoother and shorter in the hair, until they seemed likely to lose their original character altogether. Mr. Richardson says, that a small, well-marked English terrier, under seven pounds' weight, will, if as good as he looks, fetch from five to ten guineas. The celebrated dog "Billy," who killed the hundred rats in less than five minutes, was a white English terrier, with a dark patch on the side of his head.

We have already alluded to the wonderful fecundity of rats, of which, according to the writer already quoted, Mr. Shaw's little dog, "Tiny," under six pounds' weight, destroyed two thousand five hundred and twenty-five pairs; which, had they been permitted to live, would, he says, within a given time, have produced one thousand six hundred and thirty-three mil-

lions, one hundred and ninety thousand two hundred living rats! Rats destroyed by Messrs. Shaw and Sabin in two years, amounting to seventeen thousand pairs, would, had they been permitted to live, have produced, at the calculation of this writer, and in the same time, no less than ten thousand nine hundred and ninety-five millions, seven hundred and thirty-six thousand! "Now," continues the writer, "let us calculate the amount of human food that they would destroy. In the first place, my informants tell me that six rats will consume, day by day, as much food as a man; secondly, that the thing has been tested, and that the estimate given was, that eight rats would consume more than an ordinary man. Now I—to place the thing beyond the smallest shadow of a doubt—will set down ten rats to eat as much as a man, not a child; nor will I say anything about what rats waste. And what shall we find to be the alarming result? Why, that the first pair of rats, with their three years' progeny, would consume, in the night, more food than sixty-four thousand six hundred and eighty men the year round, leaving eight rats to spare! And the rats destroyed by the little wonder, 'Tiny,' had they been permitted to live, would, at the same calculation, with their three years' progeny, have consumed as much food as one hundred and sixty-three millions, three hundred and nineteen thousand and twenty men: above two-thirds of the population of Europe!"

Verily, if this be the case, it is a happy arrangement in the great scheme of Providence, that some animals that have a more than usual fecundity, have been created to destroy each other when they become too numerous, and that terriers have been so constituted to assist in the destruction of rats!

THE TURSPIT TERRIER.

This dog is a small, long-backed, cross-made thing, with the fore legs bent, first inwards and then outwards, presenting several windings, but rather of the crooked than the flowing kind, which Hogarth characterised as the line of beauty. He is a mongrel, and his name sufficiently denotes the meanness of the occupation in which he was formerly engaged. This was to turn a wheel, on which depended the spit which roasted the meat in the kitchen.

3r
In this occupation, however servile, he had certainly a chance of coming in for a share of the "good things" of this world; and if his master were not of the barbarous school, the turnspit of old may have passed his time tolerably comfortable. The appliances of modern art have long ago abolished his employment. His occupation, like that of Othello's, has vanished, and he himself is fast passing from the face of the earth, and will, no doubt, ere long become extinct.

THE HARLEQUIN TERRIER.

This beautiful little article is, in form, the perfect model of the English terrier. He is of a slate colour, like the Skye, with a little tan about the legs and muzzle. This, though not always, is frequently the case, and he possesses all the higher attributes of his species in the most marked degree. Why he has been called after that extremely active gentleman, who, in a parti-coloured dress of very tight fit and variety of hue, figures on the stage in a Christmas pantomine, we are not quite certain. Perhaps it has arisen from the various patches with which he himself is sometimes marked, and which, in the opinion of many, greatly add to his beauty. The origin of this little dog has not been satisfactorily traced, but he is now a recognised variety.

"In former times," says Mr. Richardson, to whom we have already been so much indebted, "a brace of terriers used to accompany every pack of foxhounds, for the sake of unkenneling reynard, in the event of his taking to earth. This attendance has long been discontinued, as being no longer necessary, the fox being now run into too rapidly to admit of his giving the gallant terriers this trouble. Some recent writers do not appear aware of this circumstance, but gravely furnish us with long extracts from Daniel, &c., relative to this now obsolete practice."

THE RUSSIAN TERRIER.

This is a fine large specimen of his kind, and is in great demand in Scotland, on account of the valuable qualities of which he is found to be possessed. He will take the water like a spaniel, will tackle a wolf, and has all the vigilance of the most active and most keen of the Scotch breed. He stands high, being upwards of two feet at the shoulder; and, although he might, by some, be supposed to be a mastiff from his form, he does not belong to that breed, although he bears, in some points, a striking resemblance to it. He stands straight and well up; looks formidable, and presents a front of great courage.

The colour is usually black and tan; but many are of a sort of rufus, or reddish-brown. About twenty years ago two of these dogs were to be seen in the Scottish metropolis, equal in size to many a mastiff. In Germany they are known by the name of "bear-searchers."

THE SOUTH AMERICAN TERRIER

Bears a strong resemblance to the Russian, and is remarkable for its power of destroying reptiles—escaping the bite of the serpent with a certainty which surprises, when we consider the power of that reptile to twist, turn, or coil itself in almost every direction, and round anything of ordinary dimensions. Its spring is so rapid and sure, that it will seize the serpent by the back in an instant, and immediately crush its vertebrae to fragments. It is rarely to be seen in this country; but we have noticed it as belonging to the terrier species.

THE MEXICAN PRAIRIE DOG

Is amongst the most diminutive of the canine family. It is said to burrow in its native prairies in the manner that rabbits do in this country. Of this, however, we are not aware of any well-authenticated fact, although we remember having read, in the book of some obscure Mexican traveller, that such was the case. As he is not likely ever to become acclimatised in this, or be of much use in his own country, it is of little consequence to the general world what may be the nature of his habits; although, to the professed naturalist, as well as to those who are curious in matters of natural history, no doubt, a complete knowledge of these would be highly interesting.

THE MALTESE TERRIER.

The Maltese islands lie about forty-five miles from the southern shore of Sicily, and 150 to the east of the African coast, in the neighbourhood of Cape Bonn. They are nearly due north from Tripoli, on the coast of Africa, and are
composed of a group of three—Malta, Gozo, and Comino—of which the first is by far the largest. From the first of these islands the Maltese terrier takes its name; and although it has, by some naturalists, been classed with the spaniels, its habit of vermin-killing has induced others to class it with the terriers. It is very diminutive, and is usually black, though sometimes white; but, in whatever colour he appears, he should be of but one "all over."

This little animal was well known to the ancients, as he figures upon many Roman remains. He is now, however, nearly extinct; and the celebrated animal-painter, Landseer, has immortalised him in one of his paintings, as "The Last of his Race."

THE BULL-TERRIER

Is a cross between terrier and bulldog, varying in aspect according to the sort of terrier to which he owes descent. As his name implies, he is a mongrel, but is, nevertheless, a lively courageous dog, well adapted for all kinds of mischievous sport, and affording fewer unpleasant associations than the bulldog, while he is harder than the terrier.

THE LURCHER.

The lurcher appears to be a mixed breed between the rough terrier or shepherd's dog and the greyhound, and is therefore a mongrel dog. Bewick informs us that it is shorter than the latter, with stronger limbs, and is covered with a rough coat of hair, commonly of a pale yellow colour. The scent of this dog being remarkably fine, he is often employed in killing hares and rabbits in the night. He steals silently and cautiously upon them while they are feeding, and then suddenly darts forward and seizes them.

CHAPTER V.

HOUNDS.

To introduce to and acclimatise various birds, animals, and fishes in Australia and New Zealand from this country, has, for some years, been the object of several colonists, ambitious of having the forests, fields, and rivers of their adopted homes, stored with such living remembrances of the land they have left, as may preserve it for ever in their recollections. To a large extent, we believe, success has attended their efforts; and, we think, that something in the same way might be attempted for this country, seeing that there is much living beauty scattered over the globe that might, with little expense and trouble, be here naturalised. Certainly nature has distributed over the surface of the earth the races best fitted for each climate. And nowhere can a race arrive at such perfection and beauty as in its first home. Nevertheless, there are numerous races for which other climates besides their own are adapted. And in nothing have the ingenuity and energy of man been so magnificently displayed as in the introduction of new races. The art of acclimatisation is unquestionably capable of immense development. An association has been instituted in Loudon, expressly for the purpose of improving the art to its utmost possibilities. In reference to man, the most extraordinary example of acclimatisation which modern times has produced, is the growth, by millions, of negroes in America and the West Indies. America and the West Indies are not well adapted to the European constitution; but the large, and always enlarging infusion of the negro blood will, doubtless, ultimately (if it has not already) produce the exact race the best suited for the climate. In America the results would be helped by saving from extinction the native American race. So far, however, as America is concerned, a new element is destined to come into play. The intercourse between
America and the eastern coast of Asia is rapidly extending. Already an emigration from China to America has begun. Through Russian and English influences the centre of Asia is moved, and the current will flow to the very heart of America. The central and Eastern Asiatic races are by no means comely; but they are strong—as strong in their way as the English race. In Australia, however, there is likely to be a still greater mingling of races than in America. Australia will receive hosts from Europe, hosts from Eastern and Central Asia, and hosts also from Southern Asia and Southern Africa.

Wherever the English race has penetrated, it has not failed to be the prevailing one; but it ought not anywhere to be the exclusive race. In India a large leaven of English blood is demanded. On the southern slopes of the Himalayas, and in other mountain ranges of India, colonies of Scottish Highlanders might be planted with immense advantage. But, besides, all English soldiers going to India should, when their term of service expires, settle there. This would have a manifold benefit. It would lessen the military expenditure; it would strengthen the English empire in India; and it would rapidly propagate the English language, and diffuse English civilisation. There is already no race equal to the English; but might it not at home be nobly transfigured, and thus be further moulded for its mighty achievements abroad? The English, properly so called, have sinew, solidity, indomitable endurance; but they are deficient in rapidity of movement, and in imagination. Blend with them the finest Asiatic races, and the defect is overcome. This we have already physically shown in our treatment of the English race-horse.

A beautiful experiment in acclimatisation would be to send to New Zealand the Circassians, who, by successive defeats, have been driven from their homes. The Circassians are universally admitted to be a singularly gifted, comely, and heroic race. In New Zealand they would find mountains as grand as those of the Caucasus, and no ferocious Russians to hunt them down.

But, whilst men can, almost anywhere be acclimatised, we are not so certain that this could be the case with such birds or beasts as must always be more or less under the power of climatic influence. It is not our purpose here to consider this question at large; but, in reference to the dog, we believe that even he, universal as is his distribution over the face of the earth, and hardy as is his nature, could not have his race perpetuated, if shifted from one climate to another. The dog of the tropics would not continue his race long in the higher latitudes of the temperate zone; nor would even the English dog long survive the rigours of an arctic region. Of this we have an example:—Mr. Lloyd, in his Swedish travels, was going to hunt the bear on the 16th of January, when the quicksilver was twenty-five degrees below zero; and though he was habited in his usual clothes, with the exception of an additional waistcoat, he experienced little inconvenience, as he kept himself warm with walking. From not sufficiently covering his ears, however, he got them slightly frost-bitten. What, however, was the case with Paijas, his only dog? He was an extreme sufferer. "This," he says, "was partly owing to his hair having become thin and ragged, in consequence of his advanced age. None of the native dogs, indeed, even in their full vigour, are altogether proof against the weather, if it be unusually severe. Their feet seem to be the most affected; for I have many a time seen them hold up their legs from the snow, and cry out most piteously. This being the case with animals whom Nature has provided with extremely warm jackets, it may be imagined how little able some of our thin-coated English dogs would be to face the rigours of a Northern winter.

"I saw this exemplified in two instances:—One was an English bloodhound, which Mr. Otway Cave, then member for Leicester, was so kind as to present to me; the other was a bulldog that I procured from home. Both of these dogs would, doubtless, have answered my purpose exceedingly well; but they could not exist in the forest, if the quicksilver happened to be a few degrees below zero. On one occasion, indeed, the bulldog became so benumbed with the cold, that his limbs absolutely stiffened; when, to save his life, I was obliged to cause one of my people, after putting him into a bag, to carry him a distance of some ten miles, to a habitable part of the country.
"As it was not full daylight when we reached the vicinity of the ring, we halted, and got up a good fire. This the poor dog seemed most thoroughly to enjoy; to ourselves, likewise, it was far from uncomfortable. Here we took some refreshment, which we needed, as we had breakfasted very superfliously prior to leaving Nas."

Other instances of the impossibility of acclimatising animals in such temperatures as are widely different from those to which their nature is congenial, might be adduced; but it is unnecessary here.

**THE IRISH WOLF-DOG.**

As in several other sciences, those who pursue the study of natural history, do not, in all points, agree in their opinions. Whilst the classification of the different varieties of species was founded by the great Cuvier upon their osteological structure, and craniological development; other naturalists, either from a natural desire of novelty, or from the equally natural wish to be original, and to show to the world that they have opinions of their own, have adopted other indications to decide what ought to be the standard of, or guide to canine classification. Colonel Smith seems to think that colour is the most proper guide to be adopted; whilst Mr. Martin thinks the ear, considered in relation to its size and form, is the best mark by which the variety may be determined. For us to enter upon the consideration of a subject of this kind, would only be to perplex what has already been said upon it, with, perhaps, novel ideas; but with such an amount of success as would give to ourselves little satisfaction, and, perhaps, less to our readers. All that we will say is, that we think Colonel Smith's theory is not likely to be adopted by the scientific naturalist; and that Mr. Martin's is something like judging of the character of a man's mind by the form and dimensions of his auricular organ. Cuvier's system is the least likely to lead to error, and, therefore, the more likely to be the most universally adopted. In reference to this system, in so far as the dog is concerned—and it is to no further extent that we refer—Mr. Richardson has given his assent, considering that the arrangement of the Frenchman has made all the varieties of the domestic dog easily to be divided into three classes.

In treating of the Irish wolf-dog, Mr. Richardson has separated it from both the Highland deer-hound and the Scottish greyhound; but this he has done from no conviction of its being right, but simply in deference to general opinion, which, he considers, incorrect, as "these three dogs, though originally identical, are now, unquestionably, distinct in many particulars." We shall treat them indiscriminately, as the distinctions between them, originally, would seem to have been very little.

"Silius describes a large and powerful greyhound as having been imported into Ireland by the Belge; thus identifying the Irish wolf-dog with the celebrated Belge dog of antiquity, which we read of in so many places, as having been brought to Rome for the combats of the amphitheatre."

Hollinshead says of the Irish—"They are not without wolves, and greyhounds to hunt them, bigger of bone and limb than a colt." Campion also speaks of him as a "greyhound of great bone and limb." Evelyn, describing the savage sports of the bear-garden, says—"The bulldogs did exceedingly well; but the Irish wolf-dog exceeded, which was a tall greyhound, a stately creature, and did beat a cruel mastiff." Here we have an actual comparison of powers, which marks the dog to have been a greyhound, and quite distinct from a mastiff.

In the second edition of Smith's *History of Waterford*, the Irish wolf-dog is described as much taller than a mastiff, and as being of the greyhound form, unequalled in size and strength. Mr. Smith writes—"Roderick, King of Connaught, was obliged to furnish hawks and greyhounds to Henry II."

In the *Antiquities of Ireland*, by Sir James Ware, the wolf-dog is prominently spoken of:—"I must here take notice," he says, "of those hounds, which, from their hunting of wolves, are commonly called wolf-dogs, being creatures of great strength and size, and of a fine shape. I cannot but think that these are the dogs which Symmachus mentions in an epistle to his brother Flavianus. 'I thank you,' says he, 'for the present you made me of some Canes Scotici, which were shown at the Circensian games, to the great astonishment of the people, who could not judge it possible to bring them to Rome otherwise than in iron cages.' I am sensible Mr. Burton (Itinerary
of Anton., 220), treading the footsteps of Justus Lipsius (Epist. ad Bely. Cent., i., p. 44), makes no scruple to say, that the dogs intended by Symmachus were British mastiffs.

But, with submission to great names, how could the British mastiff get the appellation of Scoticus in the time of Symmachus? For he was consul of Rome in the latter end of the 4th century; at which time, and for some time before, and for many centuries after, Ireland was well known by the name of Scotia, as I have shown before (Chap. I.) Besides, the English mastiff was no way comparable to the Irish wolf-dog in size or elegant shape; nor would it make an astonishing figure in the spectacles exhibited in the circus. On the other hand, the Irish wolf-dog has been thought a valuable present to the greatest monarch, and is sought after, and is sent abroad to all quarters of the world; and this has been one cause why that noble creature has grown so scarce among us, as another is the neglect of the species since the extinction of wolves in Ireland; and even of what remain, the size seems to have dwindled from its ancient stateliness.

"When Sir Thomas Rowe was ambassador at the court of the Great Mogul, in the year 1615, that emperor desired him to send for some Irish greyhounds, as the most welcome present he could make him; which being done, the Mogul showed the greatest respect to Sir Thomas, and presented him with his picture, and several things of value.

"We see, in the public records, an earlier instance of the desire foreigners have had for hawks and wolf-dogs of Irish growth. In a privy seal from King Henry VIII. to the lord deputy and council of Ireland, wherein his majesty takes notice, 'that at the instant suit of the Duke of Alberkyre of Spain (of the privy council to Henry VIII.), on the behalf of the Marquis of Desarry and his son, that it might please his majesty to grant to the said marquis and his son, and the longer liver of them, yearly out of Ireland, two goshawks and four greyhound; and forasmuch as the said duke hath done the king acceptable service in his wars, and that the king is informed that the said marquis beareth to him especial good-will, he therefore grants the said suit, and commands that the deputy for the time being shall take order for the delivery of the said hawks and greyhounds, unto the order of the said marquis and his son, and the longer liver of them yearly; and that the treasurer shall take the charges of buying the said hawks and hounds.'

"It is true that British hounds and beagles were in reputation among the Romans, for their speed and quick scent. Thus Nemesian, in his Canegetics:

'Veloces, nostroque orbis venutibus aptos.'

'Great Britain sends swift hounds,
Fittest to hunt upon our grounds.'

And Appian calls the British hound σκυλός ἑν ίππειρόνος, a dog that scents the track of the game. But this character does not hit the Irish wolf-dog, which is not remarkable for any great sagacity in hunting by the nose.

"Ulysses Aldrovandus, and Gesner, have given descriptions of the Canis Scoticus, and two prints of them very little different from the common hunting-hound. 'They are,' says Gesner, 'something larger than the common hunting-hound, of a brown or sandy spotted colour, quick of smelling, and are employed on the borders between England and Scotland to follow thieves. They are called sleut-hounds.' In the Regium Majestatem of Scotland, is this passage:—'Nullus perturbat aut impediat Canem trasantem aut, homines trassantes cum ipso sequendum latrones, aut ad capiendum latrones:'—(Nobody shall give any disturbance or hindrance to tracing-dogs, or men employed with them to trace or apprehend thieves or malefactors). This character no way agrees with the Irish wolf-dog; and the reader must observe, that when Gesner and Aldrovandus wrote, in the 16th century, modern Scotland was well known by the name of Scotia, which it was not in the 4th century, when Symmachus wrote the aforesaid epistle; and therefore the Canis Scoticus, described by Aldrovandus and Gesner, were dogs of different species.'

Buffon regards the French Mâtin and the great Danish dog as the main stocks of the greyhound race; but this is not clear. In Scotland and Ireland, there existed, in very ancient times, a noble breed of greyhounds used for the chase of the wolf and the deer, and which appears to be the pure source of
our present breed. It is quite as probable that the mātin is a modification of the ancient greyhound of Europe, represented by the Irish greyhound or wolf-dog, as that it is the source of that fine breed. Few, we believe, of the old Irish greyhound exist. In Scotland the old deer-hound may still be met with; and though it exceeds the common greyhound in size and strength, it is said to be below its ancient standard. With the extinction of the wolf, the necessity of keeping up the race to the highest perfection ceased. The hair is wiry, the chest is remarkable for volume, and the limbs are long and muscular. A similar breed existed, and still continues to exist, in Albania, and was celebrated by the ancients for its prowess. In England, the greyhound was larger and stronger formerly than at present, and employed in chasing the stag. Queen Elizabeth was gratified one day, after dinner, by seeing from a turret, sixteen deer pulled down by greyhounds upon the lawn at Cowdrey Park, in Sussex.

In Arabia, Persia, and other parts of the East, a breed of greyhounds has existed from time immemorial. These dogs strongly resemble light coursing dogs, represented in Egyptian paintings, and are probably descended from them. Of the same type are the semi-wild, unowned street-dogs of Egypt, Syria, and South-western Asia. From the antiquity of the greyhound breed, we might be induced to suppose, that in it is to be seen the nearest approach to the primitive source, or one of the primitive sources of the reclaimed race; and, perhaps, the Arabian greyhound, or the lurcher-like street-dogs of Egypt, retain some characters in common with the primitive stock. Care and attention have elevated the British greyhound far above the ancient Egyptian coursing dog, or that of Arabia, of which the form of the head is woolish, the tail fringed with long hair, and the ears, as seen in the paintings of the ancient Egyptians, erect and very acute. The Turkman watch-dog, for guarding sheep, is described as a large, rugged, fierce animal, equaling the wolf in stature, shaped like the Irish greyhound, and with equally powerful jaws. The ears are erect; the tail rather hairy; the general colour deep yellowish red. This race is of great antiquity, and doubtless still retains much of its pristine aspect, which is so wolf-like, that, according to Colonel Hamilton Smith, "a friend being present in Asia Minor at a wolf-hunt, allowed one (a wolf) to pass out of a brake, because he mistook him for one of the Turkman dogs."

In the Highland, or Celtic poems of Ossian, professedly translated by Macpherson, we find the ancient Irish wolf-dog, or the Scottish deer-hound, the subject of several traditions. "Bran" was the favourite dog of Fingal, the famous hero. In Mr. Scrope's volume on "Deer-stalking," we find the following:—

"Fingal agreed to hunt in the forest of Sledale, in company with the Sutherland chief, his contemporary, for the purpose of trying the comparative merits of their dogs. Fingal brought his celebrated dog Bran to Sutherland, in order to compete with an equally famous dog belonging to the Sutherland chief, and the only one in the country supposed to be any match for him. The approaching contest between these fine animals created great interest. White-breasted Bran was superior to the whole of Fingal's other dogs, even to the 'surly strength of Luath,' but the Sutherland dog, known by the full-sounding name of Phorp, was incomparably the best and most powerful dog that ever eyed a deer in his master's forests.

"When Fingal arrived in the forest with his retinue and dogs, he was saluted with a welcome that may be translated thus:—

"With your nine great dogs,
With your nine smaller game-starting dogs,
With your nine spears,
Unwieldy weapons!
And with your nine grey, sharp-edged swords,
Famous were you in the foremost fight."

"The Sutherland chief also made a conspicuous figure, with his followers, and his dogs, and weapons for the chase. Of the two rival dogs, Bran and Phorp, the following descriptions have still survived amongst some of the oldest people in Sutherland. Bran is thus represented:—

"The hind leg like a hook or bent bow;
The breast like that of a garron;
The ear like a leaf."

"Such would Fingal, the chief of heroes, select from amongst the youth of his hunting-dogs. Phorp was black in colour, and his points are thus described:—
THE DOG, AND ITS VARIETIES; [ST. BERNARD DOG.

"...Two yellow feet, such as Bran had;
Two black eyes,
And a white breast;
A back narrow and fair,
As required for hunting;
And two erect ears of a dark-brown red."

"Towards the close of the day, after some severe runs, which, however, still left the comparative merits of the two dogs a subject of hot dispute, Bran and Phorp were brought front to front, to prove their courage; and they were no sooner united than they sprang at each other, and fought desperately. Phorp seemed about to overcome Bran, when his master, the Sutherland chief, unwilling that either of them should be killed, called out, 'Let each of us take away his dog.' Fingal objected to this; whereupon the Sutherland chief said, with a taunt, that 'it was now evident that the Fingalian did not possess a dog that could match with Phorp.'

"Angered and mortified, Fingal immediately extended his 'venomous paw,' as it is called (for the tradition represents him as possessing supernatural power), and with one hand he seized Phorp by the neck, and with the other, which was a charmed and destructive one, he tore out the brave animal's heart. This adventure occurred at a place near the March, between the parishes of Clyne and Kildonan, still called 'Leck na Con' (the Stone of the Dogs); there having been placed a large stone on the spot where they fought. The ground over which Fingal and the Sutherland chief hunted that day is called 'Dirrie-leck-Con.' Bran suffered so severely in the fight, that he died in Glen Loth before leaving the forest, and was buried there. A huge cairn was heaped over him, which still remains, and is known by the name of 'Cairn Bran.'"

Thus, whilst the ancient Highland chiefs piled a cairn, or heap of small stones, on the graves of their favourite dogs, modern admirers erect to them monuments, and engrave upon them epitaphs, which celebrate their virtues.

The original greyhound was a long-haired dog; and the modern smooth-coated and thin animal, now known by that name, is comparatively of recent date. Of this we have sufficient evidence in the ancient monuments of Egypt, where, as well as in Persia and India, rough greyhounds of great size and power still exist. A dog of the same kind has been described by H. Smith, as well known in Arabia; and a gigantic rough greyhound was found by Dr. Clarke, on the confines of Circassia, and by him described as identical with our old Irish greyhound.

THE NEWFOUNDLAND, LABRADOR, AND ST. BERNARD DOGS.

We are inclined to consider the Italian wolf-dog, used in the Abruzzi by the shepherds to defend their flocks, the Newfoundland and Labrador dog, and the Alpine dog, as the representatives of a distinct group; the latter dog, indeed, approximates to the mastiff. We have seen several noble specimens of the Alpine, or St. Bernard breed: their size is equal to that of the largest mastiff; the head is deep; the ears are pendulous; the fur is rather long and wiry; the eye is full and very expressive; and the form of the body and limbs indicates great strength. Their sense of smell is very acute, and aids them in the work of supply to which the worthy monks of the convent of the Great St. Bernard have applied them. To the honour of those excellent men be it spoken, that while others have trained the dog to the combat, to the chase of the runaway slave, and to the pursuit of game, they have availed themselves of the power, intelligence, and courage of the animal, to rescue the unhappy traveller from the horrors of death amidst the snows of the mountains.

One of these noble dogs was decorated with a medal, in commemoration of his having saved the lives of twenty-two persons, who, but for his sagacity, must have perished. He was lost in 1816, in an attempt to convey a poor traveller to his anxious family. The man was a Piedmontese courier, who arrived at St. Bernard in a very stormy season, labouring to make his way to the little village of St. Pierre, in the valley beneath the mountain, where his wife and children dwelt. It was in vain that the monks attempted to check his resolution to reach his family. They at last gave him two guides, each of whom was accompanied by a dog, of which one was the remarkable creature whose services had been so valuable to mankind. Descending from the convent, they were in an instant overwhelmed by two avalanches; and the same common destruction
waited the family of the poor courier, who were toiling up the mountain to obtain some news of their expected friend; they all perished. A story is told of one of these dogs, who having found a child unhurt, whose mother had been destroyed by an avalanche, induced the boy to mount upon his back, and thus carried him to the gate of the convent. The incident forms the subject of a French print.

The wolf-dog of the Abruzzi is pure white, somewhat more lightly formed than the Newfoundland dog, but strong and muscular, and the hair is long and flowing.

What our ancestors suffered from the ravages of wolves, may readily be inferred from the various plans which are, at the present day, adopted in other countries infested by them for their rapid destruction.

Mr. Greiff, one of the oldest and best sportsmen in Sweden, dwelt in Stockholm, and took a very prominent part on the occasion of the political convulsions which agitated that country between 1820—'30. It was he who seized the person of the king Gustavus, in which act the monarch slightly wounded him with a sword which he then held in his hand. Mr. Greiff, however, being a man of herculean strength, wrested this weapon from the hand of his sovereign, and took him up in his arms, as he would have done a child, and conveyed him to a place of security. By thus peril his life, Mr. Greiff was, perhaps, a principal means of bringing about a bloodless revolution. This gentleman gives us a somewhat minute account of the plans adopted by his countrymen for the destruction of wolves in the neighbourhood of the Swedish capital. We take the account from Mr. Lloyd, whose bear and wolf-hunting exploits furnished him with the materials for a very interesting couple of volumes:

A spot covered with a tolerably thick wood of large trees, especially spruce, where the ground is undulating, and which contains fens and mosses, and of such great extent, that the pathway does not pass over fields or plains which prevent the tracing of the animals, after a fall of snow or sleet, is the suitable place for entrapping wolves. The wood must be left quiet from passengers, or woodsmen, during the time of hunting—or, in other words, the winter season; and should be situated near the centre of the parish whose peasants are to form the skall, or trap. A cottage should be near the place, that the under-huntsmen may find quarters, and have opportunity to call up in haste the men employed to fasten on the Jagttyg, or hunting-cloth, by which the daily watch of a whole division of the country, for this purpose, will be avoided.

The heewing down of trees, for the purpose of forming the skall-plat, or place of lure, should take place in the month of August or September, when the assistance of the authorities must be required. If the wood is not of the thickest and heaviest kind, the skall-plats should be ready in two to three days, with thirty to forty labourers per day.

When the skall-plat is ready, it must be kept undisturbed by the woodsmen, and from all noise.

In the month of October, when the peasants begin to kill their worn-out horses, the head-ranger gives them intimation that they shall, in conformity with orders from authority, transport them to the hunting or lure-place, and give the necessary commands for their skinning; and also that a huntsman is to be at hand to direct that the carrion should be laid in the proper place.

As soon as the ground is frozen, the hunting-cloth is brought out, which must be smoothed well down, and beaten with fir branches, so that all shall be prepared against the first falling snow; for the hunts which can be formed by the traces on the first snow, or before Christmas, are the surest.

Two huntsmen are then ordered to keep watch at the skall-plat, the day on which the snow has fallen; and they should go round it three times a day, morning and evening, and once during the night with a lantern of tin, so constructed, that it only throws light from the bottom; the marks of the animals going in and out are carefully noted each time, and written down in a journal, and whether they follow each other in numbers, or go singly.

An experienced huntsman will soon discover at what time the animals visit the carrion; the 8th, 11th, and 14th days are usually the periods, after they have once eaten of it. It happens that wolves, early in winter, get into the skall-plat, and lie there several days, without their traces being discovered; and, on such occasions,
it is necessary to drive them gently out again, in order to ascertain their number.

Each time of going round the area, every track is to be swept out with a long broom; and if the huntsman at any time have occasion to step out of the pathway, the marks should be immediately obliterated. Birds of prey, such as ravens and crows, must not be frightened away, because they entice the wild beasts by their cries, and give them confidence.

The huntsmen then examine each his side of the skall-plat: should it be found, when they meet, that traces of such animals as have entered are sufficiently numerous to fasten up the hunting-cloths, the men, for that purpose, are called out immediately; and the fastening should be executed with all possible expedition, and the whole finished within two hours.

The fastening ought to commence either at the top or at the bottom of the skall-plats, where two rolls of cloth should be lying ready. One man unloosens the roll—the other carries the pole on which it is wound. They advance along the line, unwinding as they go. The roll should be wound round the pole, so that it unwinds correctly and easily. A third man fastens the cloth round the end of each stake. When the hunting-cloth is fastened up, the men who have been so employed return each along his allotted distance, and rectifies what he finds amiss. The pieces of cloth ought to hang three feet from the ground. The huntsmen then reconnoitre the skall-plat, to ascertain whether the animals have escaped during the fastening. If that be the case, the hunting-cloths are immediately taken down, wound up, and laid in their places.

When it is found that the animals are enclosed, messengers are immediately dispatched, to apprise the people of the time of assembling for the hunt, and of the number required, according to the size of the skall-plat, reckoning eight, and, at the utmost, ten, hunting-paces between each person.

From the moment it is ascertained that the animals are enclosed, and until the hunt takes place, the utmost silence is to be observed at and about the skall-plat.

When the people are assembled, and the numbers communicated to the head-ranger, they advance silently to the skall-plat, and are formed in two divisions, either at the top or at the bottom. A huntsman goes before each division, and a huntsman after. They place each peasant in his proper situation, and inform him what he is to attend to; namely—to stand on the outside of the hunting-cloths; to remain silent, and not to go from his post; but, if the animals show themselves, he is to shake and strike against the cloths with his hunting-staff or spear.

The Skalfoedgar, or subordinate officers of the hunt, are chosen from trusty people, who are acquainted with the locality; soldiers are preferable. These, together with the superfluous huntsmen, are distributed among the body which is to advance, and should, for the preservation of better order, be distinguished by some badge.

Should there be any of the royal family present, the head-ranger himself advances in the centre; otherwise, a trusty huntsman, who should preserve a steady pace in his advance.

The driving division ought to advance slowly, because too much haste brings the people sooner into disorder. The movement ought to be effected without shots or cries; only they are to strike the trees with their hunting-poles, and examine carefully if any animal has hidden himself, or lies dead.

When the people have advanced to the farthest point, the wild animals which have been shot are conveyed to the king's skreen.

No other than good marksmen are allowed to carry a gun.

Such is the importance of the arrangements made, even at this day, in Scandinavia, for the slaying of the wolf.

THE HIGHLAND DEER-HOUND.

The Highland deer-hound has the general appearance of a high-bred greyhound, especially in all the points on which speed and power depend; but he is built more coarsely, and altogether on a larger and grander scale. The shoulder is also more elevated; the neck thicker; the head and muzzle coarser; and the bone more massive. He stands from twenty-eight to thirty inches in height at the shoulder; his coat is rough, and the hair strong; colour usually sandy yellow, iron grey, or white. All colours should have the muzzle and tips of the
ears black. A tuft, or pencil of dark hair on the tip of the ear, is a proof of high blood.

This is a very powerful dog, equally stamnuch and faithful; and when the Scottish mountains swarmed with stags and roes, it was held in high estimation, as being capable of following the deer over surfaces too rough and fatiguing for the ordinary hounds of the low country. "The general aspect of the Highland hound," says Mr. Richardson, "is commanding and fierce. His head is long, and muzzle rather sharp; his ears pendulous, but not long; his eyes large, keen, and penetrating, half-concealed among the long, stiff, and bristly hair with which his face is covered; his body is very strong and muscular, deep-chested, tapering towards the loins; and his back slightly arched. His hind quarters are furnished with large prominent muscles; and his legs are long, strong-boned, and straight—a combination of qualities which gives him that speed and long duration in the chase for which he is so eminently distinguished. His hair is wiry and shaggy, of a reddish sand colour, mixed with white; his tail is rough, which he carries somewhat in the manner of a stag hound, but not quite so erect. This is the dog formerly used by the Highland chief-tains of Scotland in their grand hunting parties; and is, in all probability, the same noble dog used in the time of Ossian. The Scottish Highland greyhound will either hunt in packs or singly."

The following description of deer-coursing, written by Mr. Scrope, presents us with a faithful picture of the mode of using the hounds adapted for that purpose in the Highlands:

"No time was to be lost; the whole party immediately moved forward in silent and breathless expectation, with the dogs in front, straining in the slips; and on our reaching the top of the hillock, we got a full view of the noble stag, which, having heard our footsteps, had sprung to his legs, and was staring us full in the face, at the distance of about sixty yards.

"The dogs were slipped; a general halloo burst from the whole party, and the stag, wheeling round, set off at full speed, with 'Buskar' and 'Bran' straining after him.

"The brown figure of the deer, with his noble antlers laid back, contrasted with the light colour of the dogs, stretching along the dark heath, presented one of the most exciting scenes that it is possible to imagine.

"The deer's first attempt was to gain some rising ground to the left of the spot where we stood, and rather behind us; but, being closely pursued by the dogs, he soon found that his only safety was in speed; and as a deer does not run well up hill, nor like a roe, straight down hill, on the dogs approaching him, he turned, and almost retraced his steps, taking, however, a steeper line of descent than the one by which he ascended. Here the chase became more interesting; the dogs pressed him hard, and the deer, getting confused, found himself suddenly on the brink of a small precipice, of about fourteen feet in height, from the bottom of which there sloped a rugged mass of stones. He paused for a moment, as if afraid to take the leap; but the dogs were so close that he had no alternative.

"At this time the party were not above 150 yards distant, and most anxiously awaited the result, fearing, from the ruggedness of the ground below, that the deer would not survive the leap. They were, however, soon relieved from their anxiety; for though he took the leap, he did so more cunningly than gallantly, dropping himself in the most singular manner, so that his hind legs first reached the broken rocks below; nor were the dogs long in following him. 'Buskar' sprang first, and, extraordinary to relate, did not lose his legs; 'Bran' followed, and, on reaching the ground, performed a complete summersault; he soon, however, recovered his legs, and the chase was continued in an oblique direction down the side of a most rugged and rocky brae, the deer apparently more fresh and nimble than ever, jumping through the rocks like a goat, and the dogs well up, though occasionally receiving the most fearful falls.

"From the high position in which we were placed, the chase was visible for nearly half a mile; but some rising ground intercepting our view, we made with all speed for a higher point. On reaching it we could perceive that the dogs, having got upon smooth ground, had gained on the deer, which was still going at speed, and were now close up with him. 'Bran' was then leading, and in a few seconds
was at his heels, and immediately seized his hock with such violence of grasp, as seemed, in a great measure, to paralyse the limb, for the deer's speed was immediately checked.

"'Buskar' was not far behind; for soon afterwards passing 'Bran,' he seized the deer by the neck. Notwithstanding the weight of the two dogs, which were hanging to him, having the assistance of the slope of the ground, he continued dragging them along at a most extraordinary rate, in defiance of their utmost exertions to detain him, and succeeded more than once in kicking 'Bran' off. But he became at length exhausted; the dogs succeeded in pulling him down, and, though he made several attempts to rise, he never completely regained his legs. On coming up we found him perfectly dead."

The Highland chiefs of former days were wont to hunt the stag with all the pomp and magnificence of Eastern sovereigns. Under the plea of a deer-hunt, they would sometimes assemble four or five thousand of their clan, ostensibly for the purpose of driving the deer into their toils, but, in reality, for very different purposes. Walter Scott, if our memory serves us, alludes to this circumstance in his Waterley. When the government found out the secret of these "gatherings," they were suppressed by an act of parliament.

The elegant appearance of the stag has always procured for it great admiration; and although he is a native of many parts of Europe, he is supposed to have been originally introduced to this country from France.

By way of contrast to the animated prose description of Mr. Scrope, we present our readers with another, equally animated, although in the "poetical vein."

The stag, too, singled from the herd, where long
He rang'd, the branching monarch of the shades,
Before the tempest drives. At first, in speed
He, sprightly, puts his faith; and, rous'd by fear,
Gives all his swift aerial soul to flight.
Against the breeze he darts, that way the more
To leave the lessening murderous cry behind.
Deception short! though fletcher than the winds
Blown o'er the keen-air'd mountains by the north,
He bursts the thickets, glances through the glades,
And plunges deep into the wildest wood.
If slow, yet sure adhesive to the track,
Hot streaming, up behind him come again
Th' inhuman route, and from the shady depth
Expel him, circling through his ev'ry shift.

He sweeps the forest oft; and sobbing sees
The glades, mild opening to the golden day;
Where, in kind contest, with his butting friends
He went to struggle, or his loves enjoy.
Oft in the full-descending flood he tries
To lose the scent, and lave his burning sides;
Oft seeks the herd: the watchful herd, alarm'd,
With selfish care avoid a brother's woe.
What shall he do? His once so vivid nerves,
So full of buoyant spirit, now no more
Inspire the course; but fainting, breathless toll,
Sick, seizes on his heart; he stands at bay;
And puts his last weak refuge in despair.
The big round tears run down his dappled face;
He groans in anguish; while the growling pack,
Blood-happy, hang at his fair-jutting chest,
And mark his beauteous chequer'd sides with gore.

It must be acknowledged that there is something exceedingly exciting in the hunting of the larger kinds of animals, whether on horseback or foot, with dog or gun. Princes of every age and country have been remarkable for their love of the chase; and one who, within these few years, has obtained no little celebrity in the eyes of the political world of Europe, is a devoted lover of the chase. Victor Emmanuel, of Italy, is one of the most enthusiastic hunters of the day. He has hunting quarters in the vicinity of the Alps—those stupendous mountain ranges which realise to the imagination all that Byron has written of "mountain majesty." When he sets out for these quarters, as a body-guard round the royal cavalcade, there walk about forty or fifty of the hardest mountainers of these districts, armed with rusty fowling-pieces, and destined to beat the bush, and drive the game to the sportsmen. The king is habituated in a broad-brimmed wideawake, and a grey hunting-suit of coarse woollen cloth, all of one colour, agreeably to fashion. He looks a kind of bluff Henry VIII. of England, equally stout, darkly sunburnt, with a deep, almost livid, red, round and behind the ears, bristling with moustaches, stretching from the lips all across the face—not a man to be loved or valued by those who do not look below the surface. The tents destined for himself and his party he has pitched about an hour's walk up a valley, deep in a glen shut in by bare rocks—a whole craggy wilderness, the refuge of chamois and bouquetins. With the exception of the character of the game, this is thoroughly Scotch.

For a long time this heroic sovereign seemed
to think that the only occupation fit for a king was war and the chase; though he never was unmindful of the noble saying of one of his ancestors, that "a sovereign's greatest prerogative was to give and to forgive." During his father's lifetime, in peaceful days, the then Duke of Savoy was only a forester. Men saw but little of him, unless they chose to meet him in the woods of Pollenzo or Raccoon, with a double-barrelled gun on his shoulders, and so plainly attired, that a good peasant of the neighbourhood once mistook him for a gamekeeper, and offered him a three-franc bribe to shoot him a fox which laid waste his poultry-yard; when the king humoured the good man, and, effecting the object, accepted and pocketed the money. After Charles Albert's death, when Victor had to play king in the camp, in the council-chamber, and parliament, his favourite field amusements were greatly curtailed. But the gun and the rifle were never set aside; and in the hot summer he had his holiday, when he would pitch his tent near "Our Lady of the Snow," on the top of Val d'Orco; or in some even more inaccessible savage spot in Val d'Aosta, and thence run and race, and climb and creep on all-tours, on the brink of precipices, staking his royal life against the carcass of a stambecce. Stambecce-stalking on the Alps lasts naturally but a short season; yet business shortened it more and more with the subsequent aggrandisement of the state, and the deepening of political complications. His hunting habits are very austere. He robs himself of sleep, rises regularly at midnight, calls up the whole household, visits the stables, sees to horses, hounds, and guns; and, after assuring himself that all is right, and all in readiness, he snatches a few hours more rest; then up he is again at earliest daybreak; the horn is wound, the hunt is up, and away he rides as fast as the nimblest mountain mag can carry him, and then takes to his legs, and the race is between him and the swiftest quadrupeds, over crags and along gullies common men shudder only to look at. Once upon a time, it is related that he came back to Turin in great glee, telling his friends he had given chase to a bouquetin for two whole days; had parted company with his aides-de-camp, his guides, his huntsmen, every man in his suite. He had followed the coy mountain goat; he had pressed closer and closer; he had driven higher and higher up; he had knocked it up, blown all the wind out of its panting body, and had, at last, brought it back triumphant, the prize of that untamed strength which has scarcely a match anywhere.

Feats like these we might expect to see in this island, performed by some during Highland chief, in the days of George II.; but, alas! money-hunting and mongrelism have made us degenerate.

Turning from the hunting of the "buck and the roe," the chamois and the bouquetins, to that of the wild boar, a yet wilder enthusiasm is displayed.

Among the exercises that contribute most towards forming good military riders, are the hunts organised in Northern Africa, by the French Algerian authorities, for the destruction of dangerous animals. Wherever French troops are, they require to be actively employed. Accordingly, they are sent to Algeria, as to a school of adversity, to become inured to toil and hardships; and when not employed in suppressing any disturbances that may arise among the Arab tribes, or in opening up new routes, or in constructing forts and earthworks, the chase affords an opportunity for the exertion and excitement so necessary for the due maintenance of the soldier's health and vigour. During a spring excursion, made by the 1st regiment of the Chasseurs d'Afrique, a wild boar-hunt was got up at almost every halt. A scene from a hunt which took place at Bordj-Bouira, exhibits, in a forcible manner, the excitement which animates all parties engaged in it.

On arriving at the bivouac of Bordj-Bouira, the neighbouring ravines were pointed out to the colonel of the regiment, who commanded the column, as the resort of boars and other wild beasts. By his orders, a grande chasse was immediately organised, and promised more than the ordinary amount of excitement, as the natives had announced the news of a lion having been recently seen in the neighbourhood. The hunting-ground comprised a number of parallel ravines, somewhat deep, descending from the spur of the Jurjura, the ridges of the different passes inclining gradually towards the plain of the Hamza. All the country about here is either wooded or covered
with formidable thickets. There are but very few regular paths, and those only practicable for the surefooted Arab horses.

At the appointed hour, the native chiefs brought to the "meet" at least three hundred scouts, a certain number of whom were on horseback, and provided with firearms; the remainder on foot, and merely armed with matrogs, or thick sticks. All these Arabs were placed upon the same line, in the plain opposite the mountain, the shooters being distributed along the ridges, and wherever there was a chance of seeing a wild boar pass. This picturesque arrangement greatly assists the imagination in drawing for itself a beautiful scene. On a preconcerted signal being given, the scouts advanced, beating up the thickets of juniper and jujube trees, and uttering loud and almost deafening cries, so as to drive out the animals from their cover in the ravines. A troop of wild boars soon took flight in the direction of the mountain. Some of these were promptly killed by the armed scouts at their different posts—but immediately afterwards the scene changed. The Arab mounted scouts, as well as the French troopers, animated by the sight of the monstrous animals, and by the sounds of the firearms, hastened to the pursuit of the boars that had succeeded in forcing the lines of the tireurs; and then began one of those headlong races, of which it is difficult to say whether we most admire the skill and boldness of the riders, or the energy, grace, and suppleness of their Arab horses, which, going at the top of their speed, clear every obstacle with a surety of foot that is never deceived, even on the steepest and most rugged paths.

The remainder of the fugitive herd was speedily encompassed by all the huntsmen, both French and Arab being carried away and electrified, as it were, by mutual excitement. Gun-shots and pistol-shots were fired off on every side, so that there was a certain amount of danger in being present at such a mêlée; for whenever an Arab smells powder he becomes intoxicated, and fires away indiscriminately, to the right or to the left, not at all heedin who may be near—a characteristic, we may observe, that gives us so very high idea of their sporting qualifications.

The band having been thus destroyed with-out accident to the "assistants," the trumpets sounded the recall. The number of victims was fourteen full-grown boars, and six young ones. They were all brought to the place of rendezvous, and put upon mules, to be taken in triumph into the camp. The chasseurs, with their colonel at the head of the column, formed the escort; the march was enlivened by repeated flourishes of trumpets; and, at the entrance of the bivouacking-ground, a feu-de-joie was discharged in the air in front of those who had remained behind, but who had come out to meet "the return from the hunt." Not the least brilliant part of the scenes composing the general action here, must have been the great variety of the costumes, and the gaiety of the Arabian horsemen, wheeling about on their splendid steeds, under the rays of an African sun. The wild boars were afterwards arranged in order on the ground, and each sportsman sought to recognise the animal which he supposed had fallen from the effect of his weapon.

In the evening, the bivouae of the 1st regiment of chasseurs was particularly gay. The men, arranged as in small tribes, took their seats around the large kettles that gave forth an appetite-creating odour; and, as they partook of the savoury slices of boar-flesh, they related to each other the "moving events" of the day. Some openly expressed regret at not having encountered the lion; but it may readily be supposed that the majority inwardly rejoiced at having avoided him.

Changing the scene, and returning to our own island, we pause for a moment to dwell upon the principal hunting national sport of England—fox-hunting. This sport presents us with very different features from such as we have just related; but it is, nevertheless, equally exciting. There are, perhaps, now more hunting, more "meets," and more numerous fields here than there were at any former period. Ladies, too, euliven the sport by their presence; and here we may observe, that the riding-habit of these "fair creatures" was first introduced in the reign of Charles II.; but, even in the days of Queen Anne, was viewed with some degree of animadversion. This is proved by the following satirical remarks of Addison:—"Among the several female extravagancies I have already taken notice of, there is one which still keeps its
ground—I mean that of ladies who dress themselves in a hat and feather, a riding-coat, and a periwig, or at least tie up their hair in a bag or ribbon, in imitation of the smart part of the opposite sex." And he thus more particularly favours us with a description of one of these anomalous personages:—"His hair, well curled and powdered, hung to a considerable length on his shoulders, and was tied, as if by the hand of his mistress, with a scarlet ribbon, which played like a streamer behind him; he had a coat and waistcoat of blue camlet, trimmed and embroidered with silver; a cravat of the finest lace; and wore, in a smart cock, a little beaver hat, edged with silver, and made more sprightly by a feather. * * *

As I was pitying the luxury of this young person, who appeared to me to have been only educated as an object of sight, I perceived, on my nearer approach, and as I turned my eye downward, a part of the equipage I had not observed before, which was a petticoat of the same as the coat and waistcoat."

The modern huntswoman is not quite so gaily attired; but if she were, she, no doubt, would be in the fashion. Be this as it may, however, the sport of fox-hunting is not now, as it was in former times, restricted to any particular class of men. Although the old Epping Hunt, of venerable antiquity, in virtue of the right of free warren, confirmed to the citizens of London by Henry III., in 1226, has lost its former prestige, the lord mayor, aldermen, and corporation no longer proceeding to the hunt in "solemn guise," many wealthy citizens, by the aid of the railways, take their turn with the hounds at the various "meets," within a few hours' distance from town, perhaps once or twice a week, and return to look in at their offices and counting-houses just before the close of business.

Of course there is, now, as, indeed, there always was, a great disparity in the character of the fields, and the ceremonial observed in them. At "provincial" meets the costume is very ad libitum—the farmer, the horsedealer, the barrister, the little country attorney, often turning out in mufti; whilst the M.P., the city merchant, and the leading men of the county, appear in the legitimate scarlet. Leicestershire is the hunting county par excellence; and Melton Mowbray, the head-quarters.

This was, till lately, a prettily situated, insignificant town; but it is now quickly becoming a sort of metropolis for our fox-hunting aristocracy. "The uninitiated reader," says Nimrod, "would, perhaps, be surprised by an enumeration of the persons of rank, wealth, and fashion, who, during several months of every year, resign the comforts and elegancies of their family mansion, for a small house in some town or village of Leicestershire—to any, but the eye of a sportsman, nearly the ugliest county in England." The same authority gives us the following coup-d'œil of the legitimate Meltonian, which contrasts widely with the miscellaneous lot in a "provincial" hunt; and as strangely with the hunting gentry of the time of George II., as we have seen represented in a picture of Mr. Taylor, the artist. "The style of your Meltonian fox-hunter has long distinguished him above his brethren of what he calls the provincial chase. When turned out of the hands of his valet, he presents the very beau-ideal of his caste. The exact fit of his coat, the superlatively well-cleaned leather breeches, and the generally apparent high breeding of the man, can seldom be matched elsewhere; and the most cautious sceptic would generally satisfy himself on this fact at a single inspection."

One more passage from this entertaining writer and thoroughgoing sportsman, drawing the line between the fox-hunter of the eighteenth and the nineteenth centuries respectively:—"Compared with the luxurious case with which the modern sportsman is conveyed to the field—either lolling in his chaise and four, or galloping along at the rate of twenty miles an hour on a hundred-guinea hack—the situation of his predecessor was all but distressing. In proportion to the distance he had to ride by starlight, were his hours of rest broken in upon; and, exclusive of the time which that operation might consume, another serious matter was to be provided for. This was the filling his hair with powder and pomatum until it could hold no more, and forming it into a well-turned knot, or club, as it was called by his valet, which was commonly a good hour's work. The protecting mud-boot, the cantering hack, the second horn in the field, were luxuries unknown to him; and his well-soiled buskins and brown-topped

415
boots would have cut an indifferent figure in the presence of a modern connoisseur by a Leicestershire cover-side. Notwithstanding all this, however, we are inclined strongly to suspect, that out of a given number of gentlemen taking the field with hounds, the proportion of really scientific sportsmen may have been in favour of the olden times."

Another still more important change effected in modern hunting, however, is in the character of the horses. They are now higher bred than before, and much faster; but on this subject we have sufficiently spoken in the first division of this work.

Regarding the costume of the sportsmen in the days of George II., it may be observed that the gentlemen wore the heavy, square-cut, buckram-supported coat, which was generally common in society; the triangular hat; the powdered and pomatumed head, and the pig-tail appendage. The large three-cornered cocked hat, called a kevenhuller, was imported from Germany, and is a speciality of the times of the first two Georges. It is thus described by a writer of the time:—"It is shaped like an equilateral triangle, placed with the most mathematical precision on the head, somewhat elevated behind, and sloping in an unvarying angle downwards to the eyes, surrounded by a long, stiff, formal feather, rising from a large rosette of black ribbon on the dexter side."

The sight of such an apparition in a Leicestershires "meet" now-a-days, might be expected not only to astonish the riders, but even frighten the horses from their propriety.

To most English sportsmen Wales is quite unknown as a fox-hunting country; yet there are several packs kept in Pembrokeshire and the two adjoining counties. First, let us remark as to the country, that the enclosures are usually small, the fences consisting of turf walls, from six to eight feet in height; but, though rather formidable in appearance, they are a very safe kind of fence, and a horse accustomed to them jumps on and off with great ease. There are also a good many loose stone walls, and occasionally timber.

A writer in The Field, who has evidently been present at some of the "meets" in Wales, begs us to accompany him on a fine morning—say February, as there is always better sport in Wales after Christmas than before—to the "Twenston Catty Arms," a favourite meet of the hounds, where we shall probably find half-a-dozen pinks, one or two black coats, and a rough-looking farmer, mounted on a rougher pony, without any saddle, waiting for the hounds. Until their arrival he requests us to take a look at the horses and their riders; and we see in the former, well bred, short-legged ones, fit to go in most countries; and, in the latter, true-bred English sportsmen. The hounds now come up; they bear the unmistakable look of fox-hounds, but are somewhat shorter on the leg, and a little more harrier-like about their muzzles and sterns than the generality of English packs. After the usual greetings, the master moves off towards "Penbryn Gorse;" and, on our arriving at the cover-side, instead of a flat furze brake, we find a deep dingle, with a natural growth of furze on either side, with little crags of rock jutting out here and there. The knowing ones quietly cross over to the side on which the fox is likely to break, and the master waves the hounds into the cover, which suddenly becomes quite alive. Presently a whimper is heard, and then a hound opens. "Have at him Goblin!" cries the master, and a burst of merry music answers the cheer. Pug just shows his nose outside the cover, but is headed back; then dismal fears of a "chop" begin to prevail; they are, however, soon dispelled; as, after running round the cover, he breaks away at the upper end: the master sounds a few notes on his horn, and the hounds settle down on the line. "He is away for the rocks," observes a quiet-looking man in black, at the same time charging a big bank; and away we go merrily for nearly four miles, when we find ourselves on the edge of a steep dingle, across which the hounds are streaming. "The Field" here divides; the wiser half follow a gentleman on a bay, who seems to be riding straight away from the hounds. However, he makes a sudden turn, scrambles down the side of the dingle by a narrow path, and reaches the summit on the other side, just as the hounds, which have come to a slight check, hit off the scent again.

We then go on for about another mile, jump a big bank, with stiffish wattling at the top, and are then upon the open mountain. But our dangers are not yet over, as we suddenly
see the foremost horse disappear up to his
girths in a treacherous peat-bog. On we go,
leaving our unfortunate friend to extricate
himself as he best can, and pick our way
carefully among the boulders, which become
rather too plentiful to allow easy galloping.
We now see "The Rocks"—a huge volcanic
pile, heaped into fantastic shapes—looming in
the distance, and Reynard is perceived a little
way ahead, gallantly struggling to reach his
city of refuge.

The chase now becomes very exciting; the
hounds are coursing the fox; but he is within
two hundred yards of the rocks; and, if he
can but struggle on for a few seconds more,
will be safe. However, he is doomed;
"Crafty" rolls him over; the rest of the pack
rush in; and so dies the poor fox. Only three
horsemen are in at the death; but, by the
time the animal is broken up, the friends we
left in the dingle arrive; and, after a little
crashing, we turn our horses' heads homewards,
and agree that forty-five minutes in Wales is
not bad sport after all.

In fox-hunting there are frequently taken,
by man and horse, leaps which, in moments of
less excitement, would literally appal them.
On one occasion, Mr. Alex. Campbell, of Mon-
zies, when hunting with Mr. Baker's hounds,
cleared, on one of his favourite horses ("De-
ceiver"), the river Leam, being nine yards
and six inches across. Not one of the "field" at-
ttempted this daring "fly;" but Mr. Haigh tried
it in a much narrower place, and succeeded in
landing himself and horse on the right side.
Mr. Cambell's remarkable leap caused not a
little commotion in the hunting world; and a
gentleman, named Gibson, backed five of his
horses for £50 each to clear both places of the
Leam—viz., at the spot which was taken by
Mr. Campbell, and that taken by Mr. Haigh.
These horses, however, were then announced
for sale at Tattersall's; and the match had
to be made conditionally, that if they were
not sold above the reserve price, the match
should stand good; and if sold, to be no match.
As only one of them was sold, the event stood
good with four of the horses; and, after a con-
siderable amount of "beating about the bush,"
it came off near Granborough—Mr. Martin, of
Rugby, being the acceptor of the challenge.
Captain Henry Lowndes was umpire. The
narrow place was first tried, and all four horses
got over, but not without a scramble on land-
ing. The umpire decided that Gibson had
won with all four, being £50 each horse. The
wide place (Mr. Campbell's "yawner") was
then attempted with a grey horse—as noble a
looking animal as ever gazed through bridle.
With a mass of people facing him on the other
side of the river, he gallantly charged it, but
fell on the edge of the water, thereby losing
the first £50. Had the hounds been in full
cry, and nothing to face him, perhaps he would
have accomplished the feat. It was, however,
a great task to undertake, on the part of the
nags, in cold blood. The two next horses were
not put to it. The fourth, however, was sent
at it in gallant style, but unfortunately jumped
into the middle of the water. They were all
ridden by one man, who appeared to weigh
about 9st.; and, considering that he received a
ducking on each occasion, he rode with great
spirit and determination. He did not, however,
appear to handle his horses as a first-rate artist
—he seemed "at sea" on one or two occasions
with his hands; but a finer seat on horseback
could hardly be seen. The match, therefore,
ended thus:—Mr. Gibson's horses won over the
narrow place, and lost over the wide part:
and Mr. Campbell's feat still remains unsur-
passed.

The patronage which the chase receives in
England is universal. The poor and the
plough-boy alike participate in its exhilarating
scenes; and even the senator, who sways the
destinies of the kingdom, may occasionally be
found in the field. The late Lord Palmerston
was a great friend to the sport, and not un-
frequently, even when premier, might be found
joining one of the "meets" in Hampshire,
although he had passed the threescore and
ten assigned as the period of man's allotted
existence in this sublunary world. It is not
many years ago, since, at Parley church, he
met the Hursley hounds, which were thrown
into Parnell Wood. In less than five minutes
a hound challenged (which summons the
huntsman said could not be a mistake). Im-
mediately a view-halloo was given; one ring
round the cover, and away they went at a
slapping pace over the open, through Mitchel-
marsh, nearly down to the "Dog and Crook." There
he turned to the left, the going bounds
forcing him back over Eldon farm, and then over the open to Compton House, where the fox ran to ground in view, after a good hour and ten minutes—in fact very few were up, the pace being so good, and the country very heavy. A great many of the field here left, being quite satisfied with the above runs; but not so with all; for a fox had stole away, but Mitchellmarsh Summers got on his line, and was up to him at Parnell, where the first fox was found. He immediately broke by Ashley Hangers, through Ashley Wood, and then took the open over Westley farm, leaving Sparsholt on the right, to Norwood, and then again over the open nearly to Winchester. He then went over the railroad to Abbots Worthy, and took the side of the rail to Hook-pit farm; then again over the railroad and recrossed it about a mile up, making his point for Pile's farm; then through the Bailey covers to Steching Wood, and from there into Lord Ashburton's large covers on the Grange. It was now half-past four o'clock, and the horses belonging to the huntsman and whipper-in dead-beaten—as was every horse that lived with the hounds—so it was thought prudent to whip off. This concluded a capital day's sport: the last run, from point to point, could not be less than fourteen miles, and the ground run over from twenty to twenty-five miles; time, two hours thirty-five minutes. This is supposed to have been one of the best runs seen in Hampshire; and the first man in England, while we write, commenced the day with the hounds; but whether he was as staunch to the end of the chase as he is to the end of a debate in the House, the Sporting Chronicle does not say.

Whilst this indomitable spirit of fox-hunting pervades, more especially, the aristocratic and provincial population of England, it is not less prevalent amongst certain classes of the Scotch. The Linlithgo and Stirlingshire fox-hounds have long enjoyed a high celebrity. One of the most brilliant runs which ever took place in that country occurred when the pack was under the management of the Honourable James Sandilands. The "meet" was announced for Stonebyres. This place, well known to the admirers of natural scenery for its romantic waterfall, and to sportsmen as a sure find for the "gallant varmint," attracted on that day a goodly number, not only of the regular attendants on the hounds, but also of the well-mounted members of a neighbouring hunt.

The morning rose bright, sunny, and dry, no rain having fallen for some time—so much so, that some of those learned in the art "of venerie" even doubted the possibility of sport; but here was a fresh instance that Dame Nature cannot be reduced to scientific rules, for this conjecture was happily frustrated. The hounds having been thrown into the cover, whimpers were heard; but practised hunters doubted their correctness, roe-deer being on foot in the cover, and being subsequently viewed, and many passed round to the south-east part of the Stonebyres' plantation. A farmer suggested a trial of a fine piece of gorse, lying on the side of the hill. The hounds no sooner entered this, than the well-known challenge resounded, and reynard was viewed leaving the gorse at a thundering pace. Onward he went across the Blackhill, making his point in a westerly direction, over a strongly fenced country. The start had been so sudden and unexpected, that many of the field did not get well away with him; the first fence, a good rattling stone wall, on boggy ground on both sides, making several reputed good horses bolt and refuse. Now came the tug of war—now came the chapter of accidents. Some of the "good men and true," going at racing pace, down hill, over ploughed ground, were thrown, horse and man, head over heels. But the pace was too good to inquire after their fate. Horses were seen flying without riders, and with difficulty caught, the gallant huntsman himself not escaping the chapter of accidents. The scent was burning; an almost impracticable fence was ridden at by him; both horse and rider kissed their mother earth; but up and away—the huntsman is of too good stuff to be beaten, though his pluck was severely tried this memorable day, having had three falls. The splendid fox now changed his point, and, crossing the banks of the romantic Nethan water, took a southerly line, and skirting the grounds of Auchtifardlo, towards Mansfield and Netherhouse, on towards Lussmahago. He then tried back down to the water; but finding that dangerous, back he went towards the south. He now crossed the
read, and was then viewed by a man dead bent, and just managed to reach his point—a drain at the foot of the field, close to the village of Lasmahago. Up came the huntsman, who rode brilliantly in spite of the chapter of accidents; and afterwards up came some of the "good men and true," their nags looking awfully beaten and pumped out. The scent had been burning; the pace had been killing; and the time was half-an-hour of as brilliant a thing as had ever been seen in the Carnwath country. It would be invidious to particularise who most distinguished himself in this remarkably fast and brilliant run. Let his laurels rest with him; but gallantry demands that a tribute be paid to the bold riding of a lady well known with these hounds. While the lucky sportsmen, who had managed to come up in the meantime, were taking advantage of the close vicinity of Lasmahago, to procure refreshment for exhausted nature, the gallant pack were endeavouring to dislodge reynard from his temporary retreat in the drain, which having succeeded in doing, he bolted, and, after holding out for ten minutes, he was run into and killed in the streets of Lasmahago, among some children at play; thus affording the most satisfactory of all ends, in a sportsman's eyes, to a fine run. The distance traversed during the run was not less than between eight and nine miles, which, considering the time taken, was about the fastest feat that can be done with hounds.

In this exciting sport it is truly beautiful to see the spirit and eagerness manifested by the young horse when he first feels, as it were by instinct, the nature of the duty he is about to be engaged in. In The Horse and his Rider, by Sir Francis Head, Bart., we have this subject graphically narrated. "When a young horse," he says, "that has never seen a hound, is ridden up, for the first time in his life, not to a meet, at which the whole pack are to be seen, but merely to the side of a covert, which, hidden from view, they are drawing, it might reasonably be conceived that, under such circumstances, he could not have an idea of the past, present, or future proceedings—we mean where they had come from, what they were doing, or what they were going to do. However, no sooner does a hound, from laziness, or possibly from feeling that he has been suffi-
ciently pricked by thorns, briars, and gorse, creep out for a few seconds before him, than—'Angels and ministers of grace defend us!'—the young horse pricks up his ears, stares intently at him, holds his breath, and, with a heart beating so hard that it may be not only heard but felt by the rider, he breaks out into a perspiration, which, on the appearance of a few more hounds, turns into a foam as white as soapsuds. On an old hound—by a single deep tone, instantaneously certified by a sharp, shrill, resolute voice of the huntsman—announcing to creation that the one little animal, which so many bigger ones have been so good as to visit, is 'at home,' the young horse paws the ground; if restrained, evinces a slight disposition to rear; until, by the time the whole pack—encouraged by the cheery cry, 'Have at him!'—in full chorus have struck up their band of music, he appears to have become almost ungovernable, and is evidently outrageously anxious to do—he knows not what; and, accordingly, when a sudden shriek, scream, or, as the Irish term it, 'sreech,' rather than a holla, from the opposite side of the covert briefly announces, as by a telegram, the joyous little word 'away,' suit ing his action to it, 'away' the young horse often bolts with his rider, just as likely 'away' from the hounds as with them. If he follows them, infuriated by ardour, which neither he nor his rider has power to control, he looks at nothing, thinks of nothing, until, at full speed, coming to, say, a sti f f ence, he disdains to rise at, a lesson is offered to him which, however, he is a great deal too much excited to learn by heart; and so, before his rider has had time enough to uncoil himself from his roll, the 'young 'un,' without a thought or disposition to wait for the old gentleman, leaves him on the ground to think about the hounds; while, with dangling stirrups, reins hanging loose on his neck, and outstretched neck and tail, he is once again 'up and at 'em.'"

The animal which excites this interest, and calls forth all the energies of both the English sportsman and his horse, is the common fox, the representative of the sub-genus Vulpes, characterised by a linear pupil, and a long bushy tail, and too well known to need a minute description. This wily animal is common in our island, and in most parts of Europe, extending into
Northern Asia, and is everywhere celebrated for its cunning and rapacity. As his linear pupil intimates, the fox is crepuscular, or nocturnal in his habits, but is occasionally seen abroad during the day. In general, however, it is as the dusk of the evening advances that he steals from his burrow, with noiseless steps, to prowl about for prey. His senses of smell and hearing are extremely acute, and he listens, and sniffs the breeze, attentive to every sound, appreciating every odour. His eyes gleam as he creeps along in a crouching attitude, intent upon theft. His movements are all stealthy. He surprises the rabbit gambolling near its burrow; the hare in her form; the poultry on the perch. He slaughters all he can, reserving the overplus for a future exigency, and for that purpose buries it in the earth. In times of scarcity, field-mice, frogs, weasels, and even insects, are devoured. On the continent the fox visits the vineyards, being as partial to the ripe grapes as the jackal is.

He is solitary in his habits, and dwells alone in a burrow, which he has either made or usurped, and which is generally in some secluded situation, not readily to be discovered, and in the neighbourhood of a rabbit-warren, preserves of game, or farms. The female breeds in April, and on her, alone, devolves the entire care of the cubs. She produces three or four at a birth, in a deep burrow, where she has prepared a bed of dried leaves, grass, and moss. The young are very playful, and remain about four months with their parent, who is watchful and resolute to the extreme in their defence. Even when taken at an early age, the fox is not easily tamed, never loses his innate suspiciousness, and never becomes truly domestic. Adults are ferocious when placed in confinement, and soon die. Though slightly made, the fox is very vigorous, and bites with great severity. His powers of endurance and speed have, in this country, recommended him to all lovers of the chase, for whose gratification the breed is preserved, where possible. It has been known to run before the hounds fifty miles at a stretch. When hard pressed, he neither loses his courage nor self-possession, and puts in practice every expedient which cunning dictates to baffle the hounds, or conceal him from their search; and, if all fail, he dies, defending himself to the last, without uttering a cry. His voice is a sort of yelp, which, however, is only occasionally exerted, and never when in quest of prey. It is said by Bewick, and we have often heard it affirmed, that the fox breeds with the dog. We have also seen sharp-nosed dogs, called fox-dogs, and were at the same time assured that they were a cross between the two animals; but it has always so happened that the assertion could not be substantiated.

He who has no larger acquaintance with the oft-decried fox than from having seen him steal away from the covert side, amidst the "whoop" of the huntsman, and the bustle of the "break," or, panting for breath, and begrimed with mud, has beheld him running for life, can have little idea of the beauty of his person in his natural haunts. There, sleek as a kitten, and almost as playful, he really looks a very handsome animal; and, on a still summer's night, when the moon shines brightly, it is delightful to witness his graceful form and nimble motions. He will enter a field, perhaps—but very cautiously—occasionally stopping to see if anything is at hand; and, if not fully satisfied that all is safe, he rears himself upon his hind legs (like a dog in the act of begging), and, erecting his ears, waits for a few seconds, mute as a mouse, eager to catch the echo of the slightest sound. Assured that all is safe, his operations commence. Backwards and forwards over the field he paces; beats over the surface as carefully as a pointer his shooting-ground, and occasionally captures a mouse, or a beetle, to reward him for his patient search. Wherever low willows, oziers, gorse, and thick-bottomed furze abound, the fox is almost sure to be met with. It is generally supposed, and we think upon good grounds, that there are in this country three kinds, which, for the sake of distinction, may be called the Greyhound Fox, the Common Fox, and the Little Red Fox. Most persons who have hunted with fox-hounds cannot have failed to notice the great difference which exists between different individuals, as regards their form, colour, speed, and manners; and there are very few who would not, at a first glance, pronounce them distinct species. Naturalists, however, who have examined them scientifically, regard them as mere varieties; but those varieties are so well marked that they appear
worth describing. The three kinds which exist in Derbyshire are:

The Common Fox, already described.

The Greyhound Fox, the form of which resembles that of a greyhound dog. He is larger in size, longer on the legs, more slender in shape, and of swifter speed than the common fox, generally giving faster and more enduring chases. One of these animals has been known to run for four hours before the hounds; and he usually leaves the cover in dashing style. In colour he resembles the common fox, but has almost invariably some grisy or silvery hairs in his coat. His head is large and sharp-looking, rather broad across the cheeks; ears broad and large; nose thin and pointed; and the jet black hairs growing from the upper lip are some of them three inches in length. These foxes are occasionally met with on Charnwood Forest.

The Little Red Fox is the third, and is an animal of much smaller size than the common fox. His form is short, compact, and thick, and the colour of his coat red—hence the name. He seems to prefer the oldest covers and woods, and is supposed by many people to be indigenous to Britain, or the one from which the other kinds are descended. When leaving cover he does not gallop off boldly before the hounds, but endeavours to steal away cautiously, and frequently affords the best sport, and most protracted runs. For so small an animal his endurance is very considerable, frequently knocking up the best-bred hounds and horses. A Berkshire friend observes:—“I was once with the Craven hounds, and viewed a small red fox away from a piece of gorse, which gave us a run of sixteen miles from point to point, without a check, threading woods of five hundred acres, when, at last, she was run into by being caught in a wire. There were only six up at the death, out of sixty or seventy at the meet; and when the second whip went into the wood for the fox, I remarked to Mr. Villebois ‘that the fox we found was a remarkably small one, and red’; and, on being brought out, she proved to be the same.” This animal is found in some parts of Nottinghamshire, Derbyshire, Leicestershire, and Berkshire.

When the covers in the vicinity of parks have been drawn several times, foxes betake themselves to hollow trees, and endeavour to secrete themselves in the holes and crevices. We remember a brace once climbing a tree nearly twenty feet high, which grew in a slanting direction, and hiding themselves amongst the branches whilst the hounds were beating the brushwood beneath. The bitch displays considerable affection for her young, and, even if hard pressed by hounds, reluctantly leaves the cover where they are situated. In 1841, the Marquis of Hastings’ hounds were drawing Stamton Springs, near Calke, Derbyshire; and found a fox, which, for more than an hour, defied all effort to make her break. Several covers having been drawn blank, the huntsman was anxious to get her away, but failed; so, supposing she was a bitch that had cubs, the hounds were whipped off. This proved to be correct; for some pedestrians, who had been following the hounds, stumbled upon the hair by accident, and brought the cubs to show the hunters. They were afterwards taken back, and reared in the wood. Her breeding-place was at the bottom of a thick honey-suckle bush, through which luxuriant herbage had crept, and afforded excellent concealment. A hole, about three feet in circumference, and three inches in depth, was scooped out of the ground; and round the edges of it, dead oak and beech-leaves were ranged. The young were seven in number, shaggy and grotesque-looking objects, four of which had their brushes tipped with white hair.

In the summer of 1842, a bitch fox reared a litter of cubs in the middle of a wheat field, in the parish of Melbourne, Derbyshire. The crop was in full ear when they were discovered, and, being thick and high, afforded them excellent shelter. The spot occupied by the family was on the top of a piece of dry land, and the stems of corn were trodden down and padded close to the earth for many yards. The parents provided a most bountiful table; for, scattered around them, lay no less than two leverets, a young bantam cock, a partridge, the wings of a pheasant, besides the remains of fowls, and a vast profusion of feathers and bones. The novelty of the scene tempted the curious to visit the spot; and the dam led her family away, not quitting the field, however, but concealing them amongst the thickest parts of the crop; and, although eventually reared, they were rarely seen afterwards.

421
When a bitch has small cubs, and she becomes aware that her nest is discovered, she takes them up by one in her mouth, as a cat does her kittens, and removes them to a more secure place. The bark of the fox is most frequently heard in January and February; some individuals bark precisely like a terrier giving mouth at game. The food of this animal consists principally of beetles, reptiles, small birds, and rabbits; he will also take partridges, pheasants, fowls, ducks, geese, and even swans. A person who had spent much time in the woods, once told us that, perceiving a fox near a covert side, he stole very cautiously up to him, and found that he was playing with a field-mouse which he had just caught. The same person, once hearing a very unusual noise in the woods, went to ascertain the cause, when he found it to proceed from two foxes, who were quarrelling over a pheasant. One of the animals had captured a prize, of which it was evident the other intended to rob him.

We could fill a large amount of space with anecdotes of the different traits of character exhibited by the fox; but a few must suffice.

A Berkshire gentleman had winged a pheasant, of which his spaniels went in pursuit: he saw it running on the ground; but the pheasant had not gone far before a fine fox caught and ran off with it in his mouth across the open field, and, although the sportsman rated him hard, and the spaniels followed in pursuit, the thief got clear off with his prize.

A similar event again occurred in the same copse, and the fox mentioned was undoubtedly the same animal whose audacity was exhibited on the previous occasion. It was evident that the animal was quickly on the alert whenever he heard the report of a gun in the covert, which he frequented, for a long time, unmolested.

In 1810, the Hull Packet contained an account of a singular occurrence which took place at Owthorne, near Patrington, in Holderness. "A fine male fox made his appearance amongst a flock of lambs belonging to a widow of that place, and became so much attached to one of the lambs that he could not be driven away. The most extraordinary part of the affair was, that the lamb also declined to be parted from its strange companion, and the pair were seen daily, seldom very far from each other."

Mr. Charles S. Graves relates the following anecdote:—"A curious circumstance occurred at Ingleby many years ago. The hounds were beating the wood opposite the house, when my grandmother heard a great swearing amongst her cats in the entrance-hall, and, on going to see what was the matter, found a fox seated in the hall; on seeing her he ran along the hall, and down the steps into the cellar, and took his place behind the beer-barrel, where he was secured. No hounds had been anywhere near the house, nor had he been run at all." Foxes are particularly fond of cheese; and fish have been found near their "earths."

Having ventured to digress thus far from our subject, we will return to another description of our hounds.

Formerly two noble varieties of the hound were common in England, which are now seldom seen. We allude to the old English hound and the bloodhound.

Of the old English hound, which is described by Whittaker, in his History of Manchester, as the original breed of our island, some years since, there was to be seen a fine specimen in Lancashire. It was tall and robust, with a chest of extraordinary depth and breadth, with pendulous lips, and deeply set eyes; the ears were large and long, and hung very low; the nose was broad, and the nostrils large and moist. The voice was deep, full, and sonorous. The general colour was black, passing into tan, or sandy red, about the muzzle and along the inside of the limbs. Shakespeare's description of the hounds of Theseus, in the Midsummer Night's Dream, is true to the letter as referring to this breed, with which he was, no doubt, well acquainted:

"My hounds are bred out of the Spartan kind,
So flaw'd, so sanded; and their heads are hung
With ears that sweep away the morning dew;
Crook-knee'd and dew-lapped like Thessalian bulls;
Slow in pursuit, but match'd in mouth like bells,
Each under each."

THE TALBOT.

Besides the old English, or Southern hound, was the old English stag-hound, or Talbot, a powerful dog, but of lighter form, and more fleet than the former. From this breed has descended the still lighter and swifter foxhound of the present day. The Talbot was
formerly known as St. Hubert's breed, and was, perhaps, the oldest of our slow hounds.

THE BLOODHOUND.

Among the hounds of the "olden time" was the Bloodhound, so celebrated for its exquisite scent, and unwearied perseverance; qualities which were taken advantage of, by training it, not only to the chase of game, but to the pursuit of man. A true bloodhound (and the pure blood is rare) stands about eight-and-twenty inches in height, and is muscular, compact, and strong. The forehead is broad, and the face narrow towards the muzzle; the nostrils are wide, and well developed; the ears are large, pendulous, and broad at the base; the aspect is serene and sagacious; the tail is long, with an upward curve when in pursuit, at which time the hound opens with a voice deep and sonorous, that may be heard down the wind for a very long distance.

The colour of the true breed is stated to be almost invariably a reddish tan, darkening gradually towards the upper parts, till it becomes mixed with the black on the back; the lower parts, limbs, and tail being of a lighter shade, and the muzzle tawny. Pennant adds, "a black spot over each eye;" but some bloodhounds, which were said to have been of the original blood, had not these marks. Some—but such instances were not common—had a little white about them, such as a star in the face, &c. The better opinion is, that the original stock was a mixture of the deep-mouthed Southern hound, and the powerful old English stag-hound.

Our ancestors soon discovered the infallibility of the bloodhound in tracing any animal, living or dead, to its resting-place. To train it, the young dog, accompanied by a staunch old hound, was led to the spot whence a deer, or other animal, had been taken on for a mile or two. The hounds were then laid on and encouraged, and, after hunting this "drag" successfully, were rewarded with a portion of the venison which composed it. The next step was to take the young dog, with his seasoned tutor, to a spot whence a man, whose shoes had been rubbed with the blood of a deer, had started on a circuit of two or three miles. During his progress, the man was instructed to renew the blood from time to time, to keep the scent well alive. His circuit was gradually enlarged at each succeeding lesson; and the young hound, thus entered and trained, became, at last, fully equal to hunt by itself, either for the purpose of woodcraft, war, or "following gear," as the pursuit after the property plundered in a border foray was termed.

Laid on the track of a marauder, it kept up a steady, persevering chase, and was not baffled without difficulty. Sir Walter Scott, in his graphic description of the "stark mouse-trooper," Sir William of Deloraine, "good at need," gives, as a proof of his merit, that he "By wily turns and desperate bounds
Had baffled Percy's best bloodhounds."

And the same accomplished knight, his stern nature touched by sorrow at the sight of Sir Richard Musgrave slain, thus eulogises his dead enemy:—

"Yet rest thee God! for well I know
I ne'er shall find a nobler foe.
In all the northern countries here,
Whose word is snaffle, spur, and spear,
Thou wert the best to follow gear.
'Twas pleasure, as we look'd behind,
To see how thou the chase couldst wind,
Cheer the dark bloodhound on his way,
And with the bale rouse the fray.
I'd give the lands of Deloraine,
Dark Musgrave were alive again."

Sir Walter Scott states that the breed of bloodhounds was kept up by the Buccleuch family on their border estates till within the eighteenth century. In former ages, these dogs, or, as the Scotch called them, "Sleuthhounds," were kept in great numbers on the borders; and fugitive kings, as well as moostroopers, were obliged to study how to evade them. Robert Bruce was repeatedly tracked by them, and, on one occasion, only escaped by wading for a considerable distance up a brook, and climbing a tree which overhung the water.

"Rycht to the burn thair passyt ware,
But the sleuth-hound made slanting there,
And waevryt lang time ta and fra;
That he na certain gait couth ga;
Till at the last John of Lorn,
Persevivt the Hund the sleuth had borne."

The Bruce, Book VIII.

"A sure way of stopping the dog," says Sir Walter Scott, in a note to the Lay of the Last Minstrel, "was to spill blood upon the track, which destroyed the discriminating fineness of the scent. A captive was sometimes
sacrificed on such occasions. Henry the Minstrel tells a romantic story of Wallace, founded on this circumstance. The hero's little band had been joined by an Irishman, named Fawdon, or Fadsean, a dark, savage, and suspicious character. After a sharp skirmish at Black-Neve Side, Wallace was forced to retreat, with only sixteen followers. The English pursued with a border bloodhound. In the retreat, Fawdon, tired, or affecting to be so, would go no farther. Wallace, having in vain argued with him, in hasty anger struck off his head, and continued the retreat. When the English came up, their hound stayed upon the dead body."

Mr. Boyle, in his Treatise on Air, informs us, that a person of quality, in order to ascertain whether a young bloodhound had been well trained, caused one of his servants to walk to a town four miles off, and then to a market-town three miles from thence. The dog, without seeing the man he was to pursue, followed him by the scent to the above-mentioned places, notwithstanding the multitude of market people that went along the same road, and of travellers that had occasion to cross it; and when he came to the chief market-town, he passed through the streets without taking any notice of the people there. He ceased not till he had gone to the house where the man he sought rested himself, and where he found him, in an upper room, to the wonder of those who had accompanied him in his pursuit.

In 1803, the "Thrapstone Association"—a society formed in Northamptonshire for the suppression of felony—procured and trained a bloodhound, for the detection of sheep-stealers. In order to prove the utility of the dog, a man was dispatched from a spot where a great concourse of people were assembled, about ten o'clock, A.M., and an hour afterwards the hound was laid on the scent. After a chase of an hour and a-half, the hound found the man secreted in a tree, many miles from the place of starting.

The Cuban bloodhound, as it is termed, is a dog of Spanish descent, sagacious and savage, and which was employed by the Spaniards with atrocious barbarity in their conquest of America; and, more recently (1795), in Jamaica, against the Maroons, who had revolted, and were waging a bloody and successful war against the government forces, but which the very terror these dogs inspired, at once happily brought to a close.

The dogs used in Cuba in the pursuit of murderers and felons, have a fine scent and great power. Their colour is tan, with black about the muzzle; the ears are comparatively small; the muzzle is shorter and more pointed than in the ordinary hound, and they are shorter on the limbs. In some prints they resemble the mastiff or ban-dog, especially in the form of the head, which approaches that of the bull-dog: indeed, by many, and with reason, they are regarded more as a variety of the mastiff than the hound; and, for ourselves, we hesitate not to regard them as such. They make excellent watch-dogs, and attack both the bull and the bear with determined resolution. Their height at the shoulder is about two feet.

BEAGLE, HARRIERS, AND FOX-HOUND.

Several varieties of hounds now exist in our island; and of these, the Beagle, the Harrier, and the Fox-hound are familiar to all our readers. No country equals England in the swiftness, spirit, and endurance of its hounds; and in no country is so much attention paid to the different breeds, especially the harrier and fox-hound. The beagle was formerly a great favourite, but is now little used. It is of small stature, but of exquisite scent, and its tones, when heard in full cry, are musical. It has not, however, the strength or fleetness of the harrier, and still less of the fox-hound, and hence it does not engage the attention of the sportsmen of the modern school, who, unlike Sir Roger de Coverley, are impetuous in the field, preferring a hard run to a tame and quiet pursuit. The beagle was only employed in hunting the hare, as is the harrier; but the fox-hound is trained both for the deer and the fox. The strength and powers of scent of the fox-hound are very great, and many astonishing instances of the energy and endurance of these animals are on record.

The cost of keeping a pack of harriers, or beagles, varies according to modes and means; also according to the nature of the country in which they are maintained. In Ireland, for example, all things being equal, a pack would be kept at a cheaper rate than a similar pack might be expected to be in England. This,
However, is not always the case; and a great disparity appears in the different sums expended by different individuals in the keeping of their harriers or beagles. For example, we have heard of the owner of twelve couples of good working harriers, keeping them at a comparatively inconsiderable outlay. His plan was this:—He laboured to encourage a hunting spirit in his neighbourhood, and to get his hounds kept at the different villages or farm-houses. He employed a good pedestrian huntsman at 3s. a day, for two days in the week, to collect and hunt the hounds, and divided the hares killed between themselves and the different farmers whose grounds he hunted over; and then, at the close of the season, gave to themselves and the watchers and gamekeepers a good jollification, in the shape of a hunt-supper; and, occasionally, after a good run, quenched the thirst of the parishioners by a gallon or two of ale.

This plan he found to cement their good feeling towards the hunt, and to have a great tendency to preserve the hares, whilst the hounds were always kept strong in scent, wind, and limb; and, as he kept a horse and strong pony, he made them useful, both for hunting, hacking, and harness, and could, even then, pop in an occasional day, by having an extra gallop with an adjoining pack of fox-hounds; and if he found that he was putting too hard upon horse-flesh, he could then spare them, and go after his harriers an occasional day on foot.

If a man can do without the parade of huntsmen, whips, and all the concomitant et ceteras, he would not only find it a very great saving of expense, but add materially to his sport, the annual expenditure of which would not cost him more than £50. In carrying out this plan of economy, hounds should not exceed eighteen inches; and they should be encouraged in a morning scent, and to do their own work without being interfered with. By this means hounds are encouraged to self-persistence, and to stick close to each other. A small kennel, to rear puppies, should be got, till they are fit to be billeted abroad; and they should be bred from faultless hounds, with good-toned voices.

The economy of this mode of keeping a pack of harriers is certainly very great, and, we have no doubt, both much sport and much satisfaction could be derived from it; but, of course, much of these would depend on the state of the purse, and the physical constitution and mental organism of him who would follow it. In Ireland, a pack of harriers may be kept at much less expense than in England, even though there is in that country an additional degree of parade exhibited in accompanying the pack. A gentleman sportsman, in replying to a query on this subject, thus describes his mode of maintaining his pack:

"The query is, the probable expense of keeping from twelve to fourteen couple of harriers, to hunt two or three days a week. In endeavouring to answer this question, I must assume that the querist is living in Ireland, as I know nothing of the prices of the various necessaries in either England or Scotland. To come at facts, however, fourteen couple of hunting-hounds will consume very nearly half a ton of oatmeal in a month, which, at the average of prices in this country (15s. per cwt.), would amount to £20 per annum for meal; then comes carrion, from 2s. 6d. to 5s. a carcass, for a year's consumption, of which it would be impossible for me to state any fixed sum, the supply being so precarious; but, for my own part, I always take as many as I can get, feeling, as I do, how much it lightens the meal bill, and adds to the condition of the pack. Straw is the next item, and from £10 to £15 might safely be put down as not too much for this. Now for servants' wages. I pay my whipper 7s. a week, with board, lodging, and clothes, for which consideration he grooms one of his own horses entirely, and keeps an eye to the other; feeds and exercises the hounds, and is responsible in the same way as a kennel huntsman for the general management of the hounds: indoors, under him, there is a boiler (as we call him), at 5s. per week, who, as his name implies, boils the mess, cleans the kennel, &c. &c.; he, again, has the assistance of another boy every morning, to wash out the kennels—which, if well done, is rather a troublesome business. I do not consider a kennel could be kept decently with less help; and, of course, if the proprietor does not act as huntsman himself, he must expect his wages bill to be higher; and I doubt not some English readers will smile at what we consider very fair wages, and for which we get our work right well done."
have now, I believe, only omitted one item, and one in which the less is spent the better—viz., drugs. Sulphur is always requisite, and the supply should never be allowed to run short; and in the summer season, the ingredients requisite for dressing the pack must, of course, be procured—along with any other requisites, which the sum of £10 ought amply to provide. Fuel—as the price and convenience of obtaining this differ so materially, that in some places it forms an expensive item, while in others it is always ready to hand—I must leave your inquirer to judge for himself what addition it would form to his expenditure, merely informing him that there is no getting on without it. In my own case, using, as I do, logs of wood which I have not to buy, I consider from £8 to £10 covers the cutting and carriage. Now for the summary of the expense: meal, £90; carrion, £5 (I state a low sum for this, as I consider if a full supply of it is obtained the meal bill will be proportionately reduced); straw, £15; physic or drugs, £10; fuel, £10; wages of whip and boiler, £31 4s.; a man for one quarter of a day throughout the year, £1 11s. 3d., at the rate of 1s. per diem. To this should be added the board, lodging, and clothing of the whip, with the lodging of the boiler.

"By this it will be seen that the keep of fourteen couple of harriers stands me in the sum of £165 15s. 3d. in the year. I may, perhaps, be a little high in putting down half a cwt. per month of meal; but, if I am, it will be found that there are many little sundries that will fully balance my tax. In conclusion, I must add that, save in the meal bill, little difference would be felt between the keep of fourteen couple and twenty couple; whereas I firmly believe no fourteen couple of hounds (I speak of this country) could hunt three days a week through a season. I now come to a very important part of the question, viz., the expense of getting up a pack of hounds—a subject upon which I can speak from experience, as I smarted pretty considerably during my apprenticeship. I will merely state the facts as they appear in the kennel-ledger, as follows:—£3, £30, £18, £5, £11, £90 10s., in all a sum of £127 10s., for which consideration I got 31½ couple of hounds; to which sum I should make a very large addition for carriage, as I got them from all parts of England; 11½ couple I was made a present of; making, in all, 46 couple. Since what I call the purchasing era has passed, I have reared 32 couple of puppies; and now I can take into the field as fair and evenly-matched a pack as ever frightened the life out of the boldest reynard that ever skirred a country."

So much for Ireland; and with one more example of, and a few comments on harrier-keeping in England, we will close this part of our subject. A practical sporting gentleman, writing on the same theme, gives, from his own personal experience, the expense necessary to carry on a hunting establishment of from twelve to fourteen couples, to go out two or three times a week, and also the expense of building kennels, &c. "Having kept a pack of hounds, consisting of twelve or fourteen couples," he says, "and having built kennels for them, I know pretty well the £ s. d. items connected with such an establishment. In the first place, hounds cannot work more than three times a week. Hounds require hunting twice a week to keep them steady and in good condition; but more than this it is unreasonable to expect from them. To hunt twice a week will entail the expense of four horses—two for the huntsman, and two for his whip. These, with good management and ordinary luck, will see him through a season; but, in case of accident, I should recommend him to commence the season with five horses, which will render him completely master of his work. Nothing, in my opinion, is so great a drawback to sport as to be under-horsed; and it must ever be borne in mind that hunting harriers is far more trying to horses than hunting foxhounds; and no man can make the best of his day's sport who does not ride close with his pack in all their turnings. The expense of horse-keeping will amount to something like £45 a horse per annum. This item will, consequently, be £225. The keeping of thirteen couple of harriers will cost, in oatmeal and flesh, something like £100 per annum; a boy, to boil flesh and attend to the pack, at 7s. per week, £18 per annum; taxes for horses and hounds, something like £27; and sundries, which are at all times heavy when horses and hounds are kept, £25—thus making the yearly expense something like £395. Your kennel,
with a small boiling-house attached, may be built, with necessary convenience, for about £70. And here I would make a remark. Let the kennel and yard be placed on well-drained ground, and the floor laid on at least twelve inches of chalk, or stone of some sort, as nothing brings about kennel lameness so much as damp floors; and, if once among your hounds, the trouble is incurable, as it hangs about like a plague. In conclusion, I strongly recommend the purchasing of a pack that have been accustomed to work together, even if the first outlay seem large. I recommend this, as I am fully convinced that no plan is so unsatisfactory, and, in the long run, so expensive, as getting draughts from different lots. It entails on you the faults of every pack you procure them from; and you will be years before you have anything like a useful lot."

These estimates, especially the last, are, in the opinions of some, too high, for it is said dogs do not require palaces. Perfectly dry and well-aired barns, byres, or outhouses, and plenty of sweet straw, are all the requisites for amateur packs. Twenty couple of small beagles, to a man who has the ordinary number of servants about him, will cost but a trifle, if he can afford at all to have the luxury of a small sporting establishment. Extravagance, display, and want of care and knowledge to be economical, and overdoing things, are the great causes of things remaining undone, and why we have not half the sport which, with economy, we might have. Like the frog in the fable, we swell ourselves out till we burst; hence most of our failures, and the constant annual abandonment of mansions and manors, horses and hounds, dogs, guns, and field sports, and, often, of our country and home. No one would find fault with well-spent liberality; but it is the tomfooleries and need-notes that are at the root of the mischief, and not liberality and just expenses. Besides, how true it is that extreme selfishness and extreme prodigality often meet in the same person. Where money ought to be judiciously and liberally expended, how frequently is it withheld. Underpaid keepers; no food allowed for pheasants in the winter; no proper quantity of traps; no watchers in the egg and breeding season, and at other important times; no proper allowances or food for dogs, or of powder, shot, &c.; shepherds and farm-labourers looked upon as rascals—ungenerous and suspicious espionage exercised over them; no little donours of money, tea, or clothing to them and their wives and families; in fact, we might enumerate a whole catalogue of petty omissions which are made by men who pretend to have money and to sport, and of which they ought to be ashamed. Where is the tenant-farmer's remuneration and compliments of the season? Too often in the river Lethe. You may have palaces for stables and kennels, expensive shooting-boxes, a useless staff of idle and inefficient servants, and great general personal expenditure, and the sport—the hobby—which should be the first consideration, becomes the last.

But back to the beagles, which we will assume you have, and that you have already dry housing convenience for them, and an active and intelligent man (partially employed on other things, because the beagles will not fill up his time), who can ride or run well, and has a good notion of hunting—you need not go to any expense on those heads, except a gratuity at Christmas of £5 in addition to his wages; and your dog-keep will cost you fourpence a week each. Then there will be straw, travelling expenses if you leave home, gratuities, dog-tax, &c., in addition; but we feel satisfied that we could, if close at home, keep and hunt a pack of small beagles for a mere trifle. By the way, larch and red-deal sawdust, well dried, and used as beds for dogs, is an effectual remedy against fleas and ticks.

Perhaps one of the most extraordinary instances of cheap dog-keeping is furnished in the case of a Mr. Osbaldeston; and although it was not harriers he kept, but fox-hounds, it may be that some humble, but enthusiastic lover of sport may take a hint from it, and become a keeper of dogs, even in the centre of the great metropolis. "With half-a-dozen of children," says the Sporting Anecdotes, "as many couples of hounds, and two hunters, this Mr. Osbaldeston, clerk to an attorney, kept himself, family, and these dogs and horses, upon a salary of £60 per annum. This, also, was effected in London, without running into debt, and with always a good coat on his back. To explain this seeming impossibility, it should be observed that, after the expiration of the office hours, Mr. Osbaldeston acted as an..."
accountant for the butchers at Clare Market, who paid him in offal, the choicest morsels of which he selected for himself and family, and with the rest he fed his hounds, which were kept in the garret. His horses were lodged in the cellar, and fed on grains from a neighbour's brewhouse, and on damaged corn, with which he was supplied by a corn-chandler, whose books he kept in order once or twice a week. In the season he hunted, and, by giving a hare, now and then, to the farmers over whose grounds he sported, he secured their good-will and permission; and several gentlemen, struck with the extraordinary economical mode of his hunting arrangements, which were generally known, likewise winked at his going over their manors. This Nimrodian was the younger son of a gentleman of good family, but small fortune, in the north of England, and having, imprudently, married one of his father's servants, was turned out of doors, with no other fortune than a southern hound, big with pup, whose offspring, from that time, became a source of amusement to himself."

The animal mostly hunted by harriers is the common hare, which is found throughout Europe, and, indeed, in most of the northern parts of the world. Being destitute of weapons of defence, it is endowed by Providence in a high degree with the sentiment of fear. Its timidity is known to every one: it is attentive to every alarm, and is, therefore, furnished with ears very long and tubular, which catch the remotest sounds. The eyes are so prominent as to enable the animal to see both before and behind.

The hare feeds in the evenings, and sleeps in its form during the day; and, as it generally lies on the ground, its feet are protected, both above and below, with a thick covering of fur. In a moonlight evening many of the species may frequently be seen sporting together, leaping about and pursuing each other; but the least noise alarms them, and they then scamper off, each in a different direction. Their pace is a kind of gallop, or quick succession of leaps; and they are extremely swift, particularly in ascending high grounds, to which, when pursued, they generally have recourse: here their large and strong hind legs are of singular use to them. In northern regions, where, on the descent of the winter's snows, they would (were their summer fur to remain) be rendered particularly conspicuous to animals of prey, they change their yellow-grey dress in the autumn, for one perfectly white; and are thus enabled, in a great measure, to elude their enemies.

In more temperate regions, they choose, in winter, a form exposed to the south, to obtain all the possible warmth of that season; and in summer, when they are desirous of shunning the hot rays of the sun, they change this for one with a northerly aspect; but in both cases they have the instinct of generally fixing upon a place where the immediately surrounding objects are nearly the colour of their own bodies.

In one hare that a gentleman watched, as soon as the dogs were heard, though at the distance of nearly a mile, she rose from her form, swam across a rivulet, then lay down among the bushes on the other side, and by this means evaded the scent of the hounds. When a hare has been chased for a considerable length of time, she will sometimes push another from its seat, and lie down there herself. When hard pressed, she will mingle with a flock of sheep, run up an old wall, and conceal herself among the grass on the top of it, or cross a river several times at small distances. She never runs in a line directly forward; but constantly doubles about, which frequently throws the dogs out of the scent; and she generally goes against the wind. It is extremely remarkable that hares, however frequently pursued by the dogs, seldom leave the place where they were brought forth, or that in which they usually sit; and it is a very common thing to find them, after a long and severe chase, in the same place the day following.

The females have less strength and agility than the males: they are, consequently, more timid; and never suffer the dogs to approach them so near, before they rise, as the males. They are likewise said to practise more arts, and to double more frequently.

This animal is gentle, and susceptible even of education. He does not often, however, though he exhibits some degree of attachment to his master, become altogether domestic; for, even when taken very young, brought up in the house, and accustomed to kindness and
attention, no sooner has he arrived at a certain age, than he generally seizes the first opportunity of recovering his liberty, and flying to the fields.

While Dr. Townson was at Göttingen, he had a young hare brought to him, which he took so much pains with as to render it more familiar than these animals commonly are. In the evenings, it soon became so frolicsome, as to run and jump about his sofa and bed; sometimes in its play it would leap upon him, and pat him with its fore feet; or, while he was reading, even knock the book out of his hand. But whenever a stranger entered the room, the little creature always exhibited considerable alarm.

Mr. Borlase saw a hare that was so familiar as to feed from the hand, lie under a chair in a common sitting-room, and appear in every other respect as easy and comfortable in its situation as a lap-dog. It now and then went out into the garden; but, after regaling itself, always returned to the house as its proper habitation. Its usual companions were a greyhound and a spaniel; both so fond of hare-hunting, that they often went out together, without any person accompanying them. With these two dogs this tame hare spent its evenings: they always slept on the same hearth, and, very frequently, it would rest itself upon them.

Hares are very much infested with fleas. Linnaeus tells us, that cloth made of their fur will attract these insects, and preserve the wearer himself from their troublesome attacks. It is much hunted in almost every country.

"Poor is the triumph o'er the timid hare!
Yet vain her best precaution: though she sits
Conceal'd with folded ears; unsleeping eyes,
By nature rais'd to take th' horizon in;
And head conceal'd betwixt her hairy feet,
In act to spring away. The scented dew
Betray's her early labyrinth; and deep
In scatter'd, sullen openings, far behind,
With ev'ry breeze, she hears the coming storm:
But nearer, and more frequent, as it loads
The sighing gale, she springs amaz'd, and all
The savage soul of game is up at once."

In India the hare is hunted for sport; not only with dogs, but with hawks, and some species of the cat tribe. The flesh was regarded by Moses as unclean; and, though in esteem among the Romans, was forbidden by the Druids, and by the Britons of the early centuries. It is now, though very black, dry, and devoid of fat, much esteemed by the Europeans, on account of its peculiar flavour.

Mr. Greiff, in his work on Sweden, makes some pertinent remarks relative to the chase, and the natural history of the hare in that country:

"The hare hunt, with the barriers so called, or the common hounds," he says, "is one of the pleasantest sports; but, if you do not wish to be deprived of this sport in course of time, you ought not to prosecute it at all seasons of the year. It is true that the female brings forth young three times, from March to June inclusive, and has seven to eight young each time; but the mother's indifference for her young, and the many kind of persecutions they are subject to, are the cause that few grow up. The female never places the young ones in one place, but one here, another there, and perhaps visits them only two or three times, and perhaps never. I have, however, found three under the same bush; but, as it was during a hunt, it is possible that the parturition was hastened by the chase. Besides man, who shoots and catches, the hare's enemies are the wolf, fox, dog, cat, eagle, eagle-owl, hare-owl, and hawks of different sorts. In wet and rainy weather, midges and insects fasten themselves about the eyes of the young hare, and inflame them so, that worms are bred, and entirely consume them. In the bare winter, or, in other words, if the ground be not covered with snow, his white skin betrays him. From March to August the hunting of the hare should be continued with moderation; it is likewise necessary, for the breaking-in of the hounds, to let them hunt by the scent. A prudent and old sportsman never shoots the female at that period; and if a few males are shot, it does no harm. The female is generally larger, carries herself high when she runs, and makes small bounds; the male is little, runs low, and makes wide bounds.

"It is asserted that old male hares kill the young ones; but, I believe, the case is the same with this as with other animals—that when any of them get a good station, the strongest drive the weakest from it. In the spring, it is easiest for the dogs to get them up; and, as the males ramble both night and
day, one can often find four or five with one female. The old hares are called ramlers, in the spring, when they stroll about to great distances to seek for the females. If the dogs run after one to a great distance, and the place of finding is left quiet, it is certain that the others will return to the same place. About Midsummer is the most difficult time to get them up, when the juniper-bush is in bloom, and all flowers throw out such a strong scent: the hare, also, does not require to go far for food. I have often seen, by the dew in the fields, and in the wood, that he has not moved ten steps round about; when he has hit upon buckbean (wattwæpping), or any other palatable food. In autumn and winter, the hare sits close; but in October and November the dogs can easily enough get him up. It helps, as they say, to get the hare on foot, by shouts, shots, and rattles. One may very well use five or six, or even a greater number of dogs.

"When they can be tracked on the snow, only one dog should be used, as several destroy, for each other, the track of the hare when she springs off; they are also an impediment to the sportsman while he is ringing, by frightening the hare from her seat. In autumn, the hare frequents the open country, and grounds covered with small juniper bushes; and when the snow falls, it sits sometimes in the snow-drifts, and in the furrows of corn-fields. When it is hard weather, it will sit two or three nights without going from its seat. During a thaw, it sits often on stones, and in open places; but in severe cold, in thickets and bushes. If the country for tracking will permit, that is to say, if it be sufficiently open, it is more convenient, to ride about and search for its track along the fence of corn-fields, as it goes in and out; for, to follow all the windings and turnings which it makes in the course of the night, is both fatigueing and consumes time. As long as you find the track of the hare to be so that the back feet immediately follow each other, it is a proof that it has no inclination to rest; but when it begins to go backwards and forwards in the same track, and makes one or two leaps, and sets all its four feet together almost in one point, it is certain that you have it very near, and the time has arrived not to follow the track more, but to ring it immediately. If it has gone farther than the first ring, you must make a new one. Whilst performing this operation, the sportsman should not halt, as then the hare rises easily from its seat. When it is ascertained that it has sprung up, the dog is immediately to be let loose. The hare is caught with snares in fences, or, with the usual gins, in woods and hedges. Roasted, it —especially a young hare—makes a good dish at table."

In speaking of the hare, in another part of his work, Mr. Greiff says—"At a hunt, when a female hare was shot, seven young ones, all alive, were cast to the dogs; a bitch which had lately pupped, took one of the young ones, laid it in a bush, and licked and dried it; and we sportsmen had a difficulty to get it from her, as she constantly licked and caressed it, as if she wanted to give it suck. It was carried home, and fed with milk. Eight days afterwards it was killed, by an unlucky accident, to the great mortification of all the hunting party."

In the chronological history of Great Britain, hare-hunting takes precedence of fox-hunting. "Hare-hunting," says a writer in the *Encyclo. Brit.*, "claims precedence of fox-hunting in the sporting chronology of Great Britain, and, we believe, of all other countries, inasmuch as a hare has always been esteemed excellent eating; and a fox the rankest of carriion. We gather from Xenophon that it was practised before his day, and he wrote fully upon it above three centuries before Christ; both hounds and nets being then used in the pursuit. Neither can we marvel at hare-hunting being the favourite diversion in all nations given to sporting, where the use of the horse in the field had not become common. But we will go a point farther than this, and assert, that how inferior soever may be the estimation in which hunting the hare is held in comparison with hunting the fox, no animal of the chase affords so much hunting as she does." In this we concur; and Mr. Beekford agrees with us, for he says, that "the hare, when properly hunted in a good country, will show more hunting, to those fond of seeing hounds hunt, than any other animal." In an *Essay on Hunting*, by the County Squire, he says—"The chase after the fox or stag is
violent, and little more than riding, or running; but the hare displays the very art of hunting—she affords a pleasure worthy of a philosopher—a curiosity that may justly raise the admiration of the wisest statesman, physician, or divine. I, therefore, hope for pardon from my more sprightly brethren, if I give my vote for the innocent hare above all other game.”

The hare is a very prolific animal, and, were it otherwise, the race would soon become extinct, from the numerous enemies by which it is sought and assailed. The average duration of the hare’s life is about seven years. It is pursued by dogs and foxes with mortal and unrelenting antipathy. Weasels, wild cats, and wolves, seize and devour it whenever it is within their reach; and eagles, hawks, and other birds of prey are also destructive enemies; but the most formidable of all is man. If taken young, it may be tamed and domesticated. It has occasionally been suckled and nursed by a cat.

Mr. Beckford, an excellent sportsman, makes many valuable remarks upon the harrier and the hare, and thinks that it is a fault in the former to run too fast. Scope should be given for all the little tricks of the hare, nor should she be killed needlessly. She will make a good defence when fiercely hunted; and, as far as her own safety is concerned, the hare has more cunning than the fox, and makes use of shifts to save her life far beyond all the artifices of the other. The County Squire, another good authority upon this subject, says, in reference to hare-hunting:—“I would advise a young huntsman, when the scent is well, always to keep himself far behind. At such a time, especially, if it be against the wind, it is impossible for the hare to hold forward, nor has she any mode of escaping but to stop short, and, when all are past, to steal immediately back. This is often the occasion of an irrecoverable fault in the midst of the warmest sport; and is the best trick the hare has for her life in scentsing weather. If the huntsman, therefore, is not too forward, he will have the advantage of seeing her manoeuvre, and of assisting his hounds at this critical moment. Upon sight of the hare, avoid, above all things, the vile practice of halloowing hounds off a scent to lay them on after a view. It not only spoils the dogs, by accustoming them at every fault to listen for and expect the halloo, but it is foul sporting; equally unfair, and to be condemned, to suffer the pricks of the hare’s footing to be sought for when she runs the foal; for, although it is admitted that, by such pricking and discovering her steps, no hare can escape, yet it is an unmanly mode of assisting hounds, which no huntsman, who is a sportsman, will be guilty of himself, or condone to make use of when done by others. The huntsman should never be noisy when a hare is first started; let him not only check his own forwardness, but that, likewise, of the inexperienced sportsman. Hounds are apt enough, in the first heat of their mettle, to overshoot their game, and hours of sad sport have happened from driving them too fast. Too many people think a chief part of hunting consists in halloowing loud and riding hard; but they are mistaken, and must not be offended should the huntsman swear at such practices. No tongue can be allowed but his, nor, at this particular time, ought any one to be more forward. The chief considerations for the huntsman, when the hounds are at fault, are, how long the hare has been on foot, and how far the hounds make it good; if she has not been long, and hard pressed, he must expeditiously try a wide circle, and so persist in contracting his circles, until he returns to the place where the dogs threw up. Should the hare have been driven hard, or be nearly dead run, the huntsman need only try a small compass, and that slowly and cautiously, for she will only leap off a few rods and squat, until one or other of the dogs jumps upon her. A huntsman should be careful of talking too loud to hounds, and in a key which, instead of cheering, confounds them.”

In reference to the huntsman, the same authority says—“Give me a fellow of everlasting patience and good temper, who does not consider hunting merely as his business, but who naturally loves it; one with a clear moderate voice, that speaks to an old hound when at fault, frequently and with quickness, and entices him in a tone that enforces courage, and induces him to stoop perpetually to recover the scent. It is by no means the huntsman’s business, by pricking the hare, to hit her off; in the first place, it is unfair; and, secondly, while he is poring with his eyes upon the
ground, not one in twenty of the hounds will have his nose to it. If there is a long default, the huntsman should attend to the tender-nosed dog, which, perhaps, he disregarded in the morning as a babbler, and whom he pronounced worthy of a halter for opening at nothing; his superior excellence of scenting may now show itself to have merited a different judgment, and may encourage some stancher hound to stoop, which he would not otherwise do."

Mr. Beckford, in a great measure, coincides with these remarks, and jocularly observes—"Were it customary to attend to the breed of huntsmen, as well as to that of hounds, the family of the silent gentleman, mentioned by the Spectator, would furnish an excellent cross; and that a female of his lineage, married to a knowing huntsman, would probably produce a perfect hare hunter."

It is said, that a hare generally describes a circle in her flight, either larger or smaller, in accordance with her strength; and that the female does not make so large a détourn as the male hare. Either sex, however, when, having been hunted, and yet escaped, whether by having made large or small circles, will follow nearly the same track again when pursued; much, however, will depend on her general habits, and whether the country be open or enclosed. In inclosures, and where there is much cover, the dodges of the hare form a complete puzzle to the hounds. Besides running the foil, she frequently makes doubles, which is going forward to tread the same steps back again, purposely to confuse her pursuers; and the same style in which the first double is made, she generally continues to follow, whether long or short.

We will not prolong this part of our subject, but conclude it by giving Mr. Beckford’s opinion on the harrier pack individually and collectively. "The number of hounds," he says, "should not exceed twenty couple in the field, from the difficulty of getting a greater number to run well together; and a pack of harriers (as well as fox-hounds) are incomplete if they do not. A hound that runs too fast for the rest ought not to be kept. Some huntsmen load them with heavy collars, or tie a long strap round their necks; a better way would be to part with them; whether they go too slow or too fast, they ought equally to be drafted. The hounds most likely to show sport, are between the large slow-hunting harrier and the little fox-beagle; the former are dull, heavy, and too slow; the latter are lively, light, and too fleet; the first sort have the best noses, and will kill their game at last, if the day be long enough; the other, on the contrary, dash and are all alive, but every cold blast affects them; and in a deep and wet country, it is not impossible that some of them may be drowned." He further observes—"that with great trouble, and by breeding, for many years, a vast number of hounds, he has succeeded in his endeavours of getting a cross of both kinds, with great bone and strength, into as small a compass as possible; that they were handsome, ran well together, had all the spirit that could be wished, and would hunt the coldest scent. In conclusion, harriers to be good, must be kept to their proper game."

**THE ENGLISH POINTER.**

This dog is produced by a cross between the fox-hound and the Spanish pointer, a large, big-boned hound, high in his legs, with a deep jowl, and very heavy ears. This dog is now seldom seen; like the Talbot, the source, as we presume, of the light, active, but vigorous fox-hound, the old Spanish pointer has merged into the intelligent, vigorous dog, so much prized by the sportsman for his excellent qualifications. In some breeds of pointers there is, we believe, a cross of the fox-hound, which improves their strength and energy.

The intelligence of the pointer, and the occupation in which he is so much engaged, has rendered him capable of judging between the qualities of a good and a bad shot. Capt. Brown relates the following anecdote on this subject:—"A gentleman having requested the loan of a pointer dog from a friend, was informed by him that the dog would behave very well so long as he could kill his birds; but if he frequently missed them, the dog would run home and leave him. The pointer was accordingly sent, and the following day was fixed for trial; but, unfortunately, his new master happened to be a remarkably bad shot. Bird after bird rose and was fired at, but still pursued its flight untouched, till, at last, the dog became careless, and often missed his
ENGLISH POINTER. FOR MOUNTAIN, FIELD, AND FARM. [ENGLISH POINTER.

game. As if seemingly willing, however, to give one chance more, he made a dead stop at a fern bush, with his nose pointed downward, his fore foot bent, and the tail straight and steady. In this position he remained firm till the sportsman was close to him, with both barrels cocked; then, moving steadily forward for a few paces, he at last stood still near a bunch of heather, the tail expressing the anxiety he felt, by moving regularly backwards and forwards. At last, out sprung a fine old blackcock. Bang, bang, went both barrels—but the bird escaped unhurt. The patience of the dog was now quite exhausted, and, instead of dropping to the charge, he turned boldly round, placed his tail between his legs, gave one howl, long and loud, and set off as fast as he could to his own home."

These dogs have been known to go out hunting by themselves, and if they found to return for their master, and, by gestures, induce him to take his gun, and follow them to the spot. This peculiarity, however, is not confined to them.

As Reynard kills his own mutton, as the phrase is, and supplies his own larder with rabbits, seldom destroying game, or visiting distant hen-roosts when there is an abundant number of bunnies close at hand, and following his own impulses without let or hindrance; it may possibly be excused if a pack of hounds, carrying out the idiosyncrasy principle, should get up a run to themselves, without either the voice of the huntsman to cheer them onwards, or the thong of the whips to keep them well together. A case of this description took place with the Essex Union hounds. Tired of the inaction of the kennel at Danbury, and anxious for the exercise of their good qualities as a famous pack, they managed to burst from their bounds, and commenced a chase upon their own account. They collected in a compact body, and, under the guidance of the leader of the pack, they drew the cover in the immediate neighbourhood of the common; and, having speedily found a fox, they went off in full cry, and proved that they were adepts at their work. An alarm was given; and it was not till the huntsman and whips had had a chase of three-quarters of an hour, that the truant pack were drawn off the scent, and brought safely back to the captivity of the kennel.

All these animals are very superior in the scent; but, according to the lines of Tickell, they must yield in this particular to the Talbot, or bloodhound.

"O'er all the bloodhound boasts superior skill,
To scent, to view, to turn, and boldly kill;
His fellows' vain alarms rejects with scorn,
True to the master's voice, and learned horn.
His nostrils off, if ancient fame sing true,
Trace the sly felon through the tainted dew;
Once sniff'd, he follows with unalter'd aim,
Nor odours lure him from the chosen game;
Deep-mouth'd he thunders, and inflamed he views,
Springs on relentless, and to death pursues."

Before the beginning of the present century pointers were known in Great Britain, and are now abundantly spread over these islands. They have also been transported to our colonial possessions, where it is to be hoped the breed may be perpetuated, although we fear that the want of hunting opportunity will cause them to degenerate. We have records of some of the species having exhibited traits of excellence of the very highest order. "The celebrated pointer dog Dash," says Mr. Blaine, "so admirably portrayed by Gilpin, was the produce of a Spanish pointer and a fox-hound; and the blending of the high scented powers of the Spanish pointer, and the dash, speed, and courage of the fox-hound, produced one of the best pointers that ever crossed a field, or ranged a moor, either as regarded speed, endurance, and such scented powers as carried him, at once, up to the birds, with little quartering of the ground. He was equally good at backing, which he did in a style that gained him great admiration. It is recorded that he was sold by his master, Colonel Thornton, to Sir Richard Symons, for 160 pounds' worth of Champagne and Burgundy, a hogshead of claret, a valuable gun, and a pointer. The bargain was also made with a stipulation, that if any accident happened to him, he was to be returned to Colonel Thornton for fifty guineas. It appears that Dash did break his leg, which unfitted him for any purpose but that of breeding from, and likewise that the sporting colonel gladly received him back again for the stipulated sum."

It is impossible for any one to estimate the qualities of dogs who has not witnessed their development, correctly, or even sufficiently. Dr. Shaw tells us that the French academi-
The Dog, and Its Varieties; [English Pointer.]

Academics speak of a dog of Germany, which, in a manner, is perfectly intelligible, and would call for tea, coffee, chocolate, &c. The person who evidenced the qualities of this dog, and who communicated an account of them to the Royal Academy of France, was no less than the distinguished Leibnitz—one not likely to form a hasty opinion, or coolly report an untruth. The dog, however, had been educated to his mode of speech. A little boy, the son of a peasant, imagined that he perceived in the voice of the dog the rudimental resemblance to certain words, and, therefore, took it into his head to teach him to speak. With this object in view he set to work, and spared neither time, labour, nor patience upon his canine scholar, who was about three years old when his education in the German language commenced; and he soon made such progress, that he could articulate, with some degree of distinctness, no fewer than thirty words. It appears, however, that he was somewhat of a truant, and was negligent in the exertion of his extraordinary talents—a circumstance very common, even in men of conscious ability. He was averse to his being pressed into the service of literature; so that it was necessary that the word should be first pronounced to him each time, which he, as it were, echoed from his preceptor. Leibnitz, however, attests that he himself heard him speak; and the French academicians add, that unless they had received the testimony of so great a man as Leibnitz, they should scarcely have dared to report the circumstance. This extraordinary dog was a native of Zeitz, in Misnia, in Saxony. Had this dog been a native of Japan instead of Germany, to what a degree of consideration would he not have risen! The islands of that empire form the earthly paradise of dogs. There they have every encouragement to live happily, and enjoy a perfect immunity from many of the punishments to which they are doomed by the less humane, yet more civilised Europeans. The reason for this exemption arose out of a singular superstition. An emperor, who reigned at the close of the last century, chanced to be born under the sign of the Dog, one of the twelve celestial signs of Japan; and on this account the emperor decreed that all dogs should be deemed sacred. They, accordingly, have no masters, but lie and prowl about the streets as they list, to the extreme annoyance of many of the passers-by, and especially to those who are not possessed of very strong, affectionate, canine tendencies. If a pack of these dogs take it into their sagacious heads to attack a person, he must, on no account, beat or kill them, but suffer himself to be bitten, or, perhaps, like Actaeon, devoured. To kill one of them is death by the law, no matter what may have been the ferocity of the brute. In every town there are guardians of these dogs, and they alone are empowered to punish their charges. Every street must maintain a certain number of these animals, or, at least, provide them with victuals. Huts, or dog hospitals, are erected in different parts of the towns; and to these, in cases of sickness, the patients must be carefully conveyed by the inhabitants. The dogs that die must be carried up to the tops of the hills and the mountains, the usual places of burial for the human species, and there be respectfully interred. Had the speaking dog of Germany chanced to have been born in such a community, it is impossible to say what honours might have been conferred upon him. An emperor raised his horse to the dignity of the Roman magistracy; the Emperor of Japan might, at least, have made the dog a professor of languages.

The dog is not the only animal that can be trained to point. We have heard of other species matchless even in this particular. Mr. Daniel, in his Rural Sports, records the case of a female pig, the property of Mr. Toomer, gamekeeper to Sir Henry Mildmay, that was as perfect a pointer as ever took the field. Mr. Blaine substantiates the account of Mr. Daniel, by the evidence of an eye-witness of the facts recorded. "It was certainly," he says, "a mere matter of accident that occasioned the development of the peculiar scenting powers of this extraordinary animal. The aptitude of swine, generally, in finding certain palatable roots under ground was well known to Toomer; nor was it unlikely, by what followed, that he might have entertained an opinion, that almost any keen-scenting animal could be taught both to wind game, and to stand on the point towards it; and that he was, therefore, led to allow a female pig to accompany his young.
pointers, in their breaking lessons, to the field. By that as it may, it turned out, to the surprise and gratification of the intelligent keeper, that within a fortnight from her first entry, she would hunt and point partridges or rabbits; and her training being much forwarded by the abundance of both, which were near the keeper's lodge, she daily improved, and, in a few weeks, would retrieve birds that had run as well as the best pointer; nay, her nose was superior to any pointer they ever possessed, and no two men in England had better. They hunted her principally on the moors and heaths. Slut has stood partridges, black-game, pheasants, snipes, and rabbits in the same way, but was never known to point a hare. She was seldom taken by choice more than a mile or two from the lodge, but as frequently joined them when out with their pointers, and continued with them several hours. She has sometimes stood a jack-snipe, when all the pointers have passed by it. She would back the dogs when they pointed, but the dogs refused to back her until spoken to—Toomer's dogs being all trained to make a general halt when the word was given, whether any dog pointed or not; so that she has been frequently standing in the midst of a field of pointers. In consequence of the dogs being not much inclined to hunt when she was with them—for they dropped their sterner and showed symptoms of jealousy—she did not very often accompany them, except for the novelty; or when she accidentally joined them in the forest. Her pace was mostly a trot; she was seldom known to gallop, except when called to go out shooting; she would then come home off the forest at full stretch—for she was never shut up, except to prevent her being out of the sound of the call or whistle when a party of gentlemen had appointed to see her out the next day, and which call she obeyed as readily as a dog—and be as much elated as a dog upon being shown the gun. She always expressed great pleasure when game, either dead or alive, was placed before her. She has frequently stood a single partridge at forty yards' distance—her nose in a direct line to the bird. After standing some considerable time, she would drop like a setter, still keeping her nose in an exact line, and would continue in that position until the game moved; if it took wing, she would come up to the place, and put her nose down two or three times; but if a bird ran off, she would get up and go to the place, and draw slowly after it; and when the bird stopped she would stand it as before: nor was her love of hunting confined to partridges only; but she has stood black-game, pheasants, snipes, and rabbits, and has been seen to do it to all these varieties in one day."

This, in some respects, may beat the powers even of the educated dog; but it is a rare, and, it must be acknowledged, an extraordinary instance of development in the porcine race.

THE SPANISH POINTER.

This dog is apparently one of very ancient extraction; but Mr. Richardson thinks he is not of Spanish origin—at least not remotely so; for the primitive breed is traceable to the East. The old Spanish pointer is, when perfectly thorough-bred, remarkable from having a 'left nose, similar to the Russian variety. The animal is altogether too heavy for the ardour of British sportsmen; and, with the old Talbot, or Manchester hound, has gradually passed out of notice. He has been displaced from the estimation in which he was held, by a lighter, more active, and energetic dog, more suitable to the tastes of the British sportsman; viz., the English pointer.

THE RUSSIAN POINTER.

This dog is covered with coarse, wiry hair, like the Russian terrier. He is somewhat less in stature than the ordinary pointer, and is lower in the shoulder. His nose 'left—he is frequently called the "double-nosed pointer." He is very staunch, and is held in deservedly high estimation. His temper, however, is said to be unbending, and he, therefore, requires the most careful training. When thoroughly broken in, and rendered perfectly subservient to the will of his master, he is esteemed a valuable dog, and brings a high price.

THE PORTUGUESE POINTER.

This animal is not so heavy as the Spanish pointer; and is not to be depended on, from his irritable disposition. He is very unsteady, and is favoured with a spreading tail. We introduce him here simply on account of his
bad qualities, that no person may have anything to do with him.

THE FRENCH POINTER

Wants the staunchness of our English dog. He is less objectionable than the variety just described, but still not the thing. This dog has more to commend him than the Italian, but he has not the steadiness of the English breed. We do not know why this should be; but it strikes us that these canine creatures of the Portuguese and French people participate in some degree of the idiosyncrasies of the natures to which they themselves belong.

THE ITALIAN POINTER.

This is a perfect miniature variety of a very highly-bred English pointer, seldom exceeding one foot in height. Mr. Richardson says, he saw one, about twelve years ago, in possession of Stewart Monteith, Esq., of Closeburn, Dumfriesshire; and another, about the same time, in possession of Mr. Mathew, an artist, resident in Edinburgh. These little dogs had exquisite noses, and would set game as staunchly as any other pointer, but were, of course, too small for field use.

THE Dalmatian, or Carriage Dog.

This animal greatly resembles the pointer; but is not remarkable for either its sagacity or power of scent. Notwithstanding these defects, he has been broken to the gun, and proved himself quite capable of holding his ground with other pointers. As he is not regularly trained to the field, whatever drawbacks he may have in hunting, may have sprung from that circumstance. The sagacity of dogs of every variety of breed is universally acknowledged, and there are, every day, instances of its exemplification being witnessed throughout the civilised world. One of the most extraordinary displays of the possession of this quality transpired not long ago. Messrs. — , tobacconists, closed their shop one evening, leaving their favourite Newfoundland inside. On opening the store on the following morning, the floor in the back room was found to be on fire, and the dog was labouring with his fore feet and mouth, trying to subdue it. A pail of water, which stood in the room, had been poured down the hole. The faithful animal had so successfully combated the fire as to prevent its spreading beyond a spot two or three feet square. How long the noble fellow had stood sentinel and fought down the advancing flames can only be conjectured; it must have been several hours. His feet, legs, and mouth were badly burned, and he was seriously injured internally by inhaling the hot air. He refused his food, and was apparently in much pain. He is worth his weight in gold, and may safely be pronounced the noblest of his race.

SPANIELS.

The Spaniel is a very ancient dog, the breed of which has, in various countries, received the utmost attention. In the Levant there seems to be several breeds; and even history has given the spaniel celebrity for its fidelity, and the affectionate disposition of which it is possessed. The chief order of Denmark, now called the Order of the Elephant, was instituted to commemorate the faithfulness of a spaniel, which adhered to the sovereign when his subjects deserted him. The motto to this order still exists, and it is simple, brief, and expressive—"Wildbrat was faithful." Mr. Daniel, in his Rural Sports, speaks of the amiability of a spaniel that belonged to the gamekeeper of the Rev. Mr. Corsellis. "The gamekeeper of Mr. Corsellis," he says, "had reared a spaniel, which was his constant attendant, both by day and night; wherever old Daniel, the keeper, appeared, Dash was close beside him; and the dog was of infinite use in his nocturnal excursions. The game, at that season, he never regarded, although, in the day-time, no spaniel would find it in better style, or in greater quantity; but at night, if a strange foot had entered any of the coverts, Dash, by a significant whine, informed his master that the enemy was abroad; and many poachers have been detected and caught from this singular intelligence. After many years' friendly connection, old Daniel was seized with a disease which terminated in consumption and his death. Whilst the slow, but fatal progress of his disorder allowed him to crawl about, Dash, as usual, followed his footsteps; and when nature was still further exhausted, and he
took to his bed, at the foot of it unwarily attended the faithful animal; and when he died, the dog would not quit the body, but lay upon the bed by its side. It was with difficulty he was tempted to eat any food; and although, after the burial, he was taken to the hall, and caressed with all the tenderness which so fond an attachment naturally called forth, he took every opportunity to steal back to the room in the cottage where his old master breathed his last. Here he would remain for hours; from thence he daily visited his grave; and, at the end of fourteen days, notwithstanding every kindness and attention shown him, he died literally broken-hearted." To this anecdote we may append the Danish motto, only altering the name, and say, "Dass was faithful."

"As the shepherd's dog," says Mr. Richardson, "is the faithful friend of those in the humber walks of life, so are the spaniels to 'chiefs and ladies bright'—to the gentler sex, par excellence, and to those high in 'honour and in place.' Examples of the good qualities of these dogs are everywhere notorious. As the shepherd's dog represents the utile, so may these represent the ducce. The former, the rough and honest comrade of the rough and honest peasant—the latter, the associate of luxurious courtiers and of powerful princes; but still, though moving amidst tinsel and falsehood, never losing the primitive honesty and purity of intention which characterise his disposition."

The following we take from a communication made to a respectable paper:—"I had a spaniel dog that was particularly attached to me. She seemed quite conscious when I was about to leave home for a lengthened absence, and would whine and look exceedingly miserable on such occasions; though she would suffer me to depart without any exhibition of especial regret when I was only going to the neighbouring towns for a day or two. I was informed, on credible authority, that when I was in London, or any other distant place, and wrote home, this dog would select my letter from a number of others, and, if she could possibly obtain it, would run away with it in her mouth to some secure hiding-place, and cry over it; and, perhaps, if she had found words, would have exclaimed, like Here, when perusing an epistle from Leander:—

"'With what delight I read your letter over;
Your presence only could have given me joy.'"

How far credulity may be given to this instance of sagacity, we must leave it to the reader's own judgment to decide.

THE SETTER, OR LAND SPANIEL.

This spaniel was first broken in to set partridges and other feathered game, as an assistant to the net, by Dudley, Duke of Northumberland, in 1335; and Mr. Daniel, in his Rural Sports, gives a copy of a document, dated 1685, in which a yeoman binds himself, for ten shillings, to teach a spaniel to set partridges and pheasants. That the setter and the old original land spaniel are identical, there can be no doubt.

"There are several varieties of setter. The ordinary old English setter, with rather a square head and heavy chops, looking as if he had a dash of Spanish pointer in him: colour usually liver-and-white. The Irish setter, narrower in the head, finer in the muzzle; usually of a yellowish-red colour, perhaps the fastest of all setters. This is a dog in very high esteem; no trace of the pointer is seen in him. These are the genuine, unmixed descendants of the original land spaniel; and so highly valued are they, that a hundred guineas is by no means an unusual price for a single dog. There was a celebrated breed of these dogs—now, I believe, extinct—kept by that ancient and noble Irish family, the O'Connors of Offaly: those belonging to the late Maurice O'Connor were highly renowned, and the breed is described by his grandson as yet remaining."

Of the sagacity of every variety of spaniel, we have almost innumerable instances, which, to those who are unacquainted with the mental manifestations of dogs, sometimes appear so extraordinary, that it makes credulity pause before it can admit them into the repository of its facts. On one occasion, some gentlemen were shooting in the woods belonging to Mrs. Stackpoole and Miss Wasey, of Prior's Court, when one of the party (Mr. J. Wernham Pocock, of Chieveley) discovered that he had lost his watch and chain. He recollected having them safely in his pocket about an
hour before, but had since been through a considerable portion of high cover. Fortunately, however, Mr. Pocock had a retriever dog with him, which he sent into the wood to find the missing valuables; hardly, however, supposing that he would really do so; but, upon following the animal some distance into the high wood, the dog was found to have taken his station at the stem of a small tree, into which he was anxiously looking up, and endeavouring to jump. Mr. Pocock’s gratification and surprise may be imagined, when he saw his watch and chain suspended in the tree by the bough which had drawn them from his pocket.

The nature of the setter was generally well understood two centuries and a-half ago. Gervase Markham, in his work On the Art of Fowling, says—"I know that in divers places in this kingdom the setting dogs are to be taught (so that men of ability may have them at their pleasure); yet, likewise, I know they are sold at such great rates and prices, that no industrious man whatsoever (which either loves the sport, or would be partaker of the benefit) but will be glad to learn how to make a dog himself, and so both save his purse and make his pleasure and profit both more sure and more delicate; for this I must assure all men that buy their dogs from mercenary teachers, that evermore those salesmen do reserve in their own bosoms some one secret or another, for the want of knowledge whereof the purchaser quickly finds his dog imperfect, and so is forced upon every disorder or alteration of keeping to send the dog back to his first master anew to be reformed, which, drawing on you a new price, makes the dog’s certain price without end, and without valuation. This fault to redress, and to make every man the true master of his own work, I will show you here, in a brief and compendious manner, all the mysteries and secrets which lie hid in this laborious business. The first thing, therefore, you must learn in this art, is to make a true selection of your dog which you intend to apply to this purpose of setting; and, in this selection, you shall observe, that although any dog which is perfect, and of good scent, and naturally addicted to the hunting of feathers—as whether it be the land spaniel, water spaniel, or else the mongrels between either or both of these kinds, or the mongrels of either of these kinds, either with the shallow-flewed hound, the tumbler, the lurcher, or indeed the small bastard mastiff—may be brought to this perfection in setting (as I have seen by daily experience, both in this and in other nations); yet is there none so excellent, indeed, as the true-bred land spaniel, being of a nimble and good size, rather small than gross, and of courageous and fiery metal, evermore loving and desiring toil, when toil seems most irksome and weary, which, although you cannot know in a whelp so young, as it is intended he must be when you first begin to train him to this purpose, yet you may have a strong speculation therein if you choose him from a right litter or breed, wherein, by succession, you have known that the whole generation have been endowed with all these qualities, as, namely, that he is a strong, lusty, and nimble ranger, both of active foot, wanton tail, and busy nostril; that his toil is without weariness, his search without changeableness, and yet that no delight nor desire transport him beyond fear or obedience; for it is the perfectest character of the most perfect spaniel ever to be fearful and loving to him that is his master and keeper. I confess I have seen excellent rare setting dogs made in the Low Countries, which have been of a bastard tumbler’s kind; and, indeed, I have found in them (if I may so term it) a greater wisdom (which, indeed, is but a greater fear) than in our land spaniels; but, comparing the whole work together, that is, the labour of ranging, the scent in finding, and the act of setting, they have been much inferior to our dogs, and not able to make their ways in the sharp thickets and troublesome covers, nor stand up with them in the large and spacious campaigns. To speak then, in a word, touching the best choice of this setting dog, let him be as near as you can the best bred spaniel that you can procure; and though some have been curious in observing their colours, as giving pre-eminence to the motley, the liver-head, or the white or black spotted; yet, questionless, it is but a vain curiosity, for no colour is amiss for this purpose, provided the natural qualities be perfect, and answerable for the work to which end you intend them."

Notwithstanding all the precautions taken
in training the setter, there are some of them, when taken into the field, affected with what is called "gun-shy." A gentleman, whilst shooting with a friend, on the Clune Moors, in Morayshire, observed that one very handsome setter was invariably left behind; and, upon asking the reason, was informed that he was "gun-shy," and "ran home;" but that "without the gun, no dog could beat him on the hills." He was too good-looking to be thrown away, though his owner had but slight hope, after running home, that any good could be done. However, he tried, and the plan adopted was the following:—He coupled him to a retriever (a stronger dog than the setter), and took them on the hill; at first, the "gun-shy" setter wanted to bolt, but the retriever was too fond of the sport to allow it, when a sort of "pull devil, pull tailor" performance commenced, always ending in favour of the retriever. This went on for three successive days, each day the gun-shyness wearing off; and, on the fourth morning, no symptoms of it were visible. This dog was shot over for several months, and came at last to be pronounced by far the best dog in his kennel, which is by no means the worst in the North. Let a dog see what you are firing at, and not blaze over him in a kennel or yard.

Another sportsman, who had much experience of gun-shy in setters, found the only successful means of curing them was, by taking them out with some hunting terrier or dog, where game was abundant (whether winged game, or quadrupeds, was immaterial), and allowing them to run riot as they pleased for several days; then, while at a distance, and the dogs alone, to fire an occasional shot, never allowing them to see a whip, or even speak angrily to them, until their ardour became excessive. Then, for a dog, he would shoot a hare or rabbit, and give him the entrails; and should this have proved unsuccessful in removing his terror, he would break him off the way, by tying up one of his fore legs with a pair of couples, close under his neck, and then take up amongst the guns, and check him with a check-line (a long line annexed to a collar put round his neck, by which he may be held to a set), at which time the gun would be continually used, and no harsh severity whatever.

A sportsman, writing to _The Field_, says—"I have now a setter bitch—the best, I may say, I ever saw out—which was, at one time, under the influence of this fever (gun-shy). I had almost despaired of removing this alarm, when it occurred to me, as I wished to propagate the stock of an old dog setter, I would try what 'warding' would do. The effect was wonderful. On the 1st of September, I think it was, my keeper took her out after her love affair, and shot two-and-a-half brace of birds over her; she never bolted, nor has she evinced any feeling or symptom of fear at a gun, or the report of one; and is now, and has been since that time, one of the best dogs I ever shot to. I should recommend this plan of putting the dog to a bitch. If this does not succeed, he cannot do better than follow a work on dogs, written by Colonel Hutchinson, which work, I observe, other correspondents have recommended. Patience and kindness must cure the evil; squabbing off, occasionally, (leaving the dog) may accustom him to the report of a gun—increasing the lead by degrees, and patting the dog, and giving him a piece of biscuit, cake, &c., after each discharge. Taking him out, also, with an old dog may do wonders, as a dog will more readily learn at his own species than from any other means. I have known the above remedy of 'warding' succeed in many instances."

Setters have been known to be affected with gun-shy up to eighteen months old, and after that turned out very well. These have not been actually gun-shy, but would not work off. If the dog runs away when the gun is fired off, some think they never get over it.

Mr. Richardson says—"The setter is by some sportsmen preferred to the pointer; and where water is to be got at occasionally, during a day's shooting, there can be no doubt of his superiority. He cannot, however, work without a drink as long as the pointer can, although, if he can obtain a sufficient supply, he can work still longer than that dog. In disposition, the pointer is more affectionate, and more attached to his master individually, than the setter is. He requires more training than the latter dog; but that training must be of a very mild and gentle description, lest the dog be blinked, or spirit-broken. The setter will always work best in cold and wet weather.
The pointer cannot, from his short hair, which makes him very susceptible of cold; but will stand out a day's shooting much better than the setter in very warm weather. However, the setter is decidedly the best dog for general use.

The black setter is a rare specimen, and is both staunch to his work, and beautiful. The Scotch setter stands high on his legs, but is difficult to break, from the quarrelsomeness of his disposition. He is usually of a black and tan colour.

Of the affectionate disposition of the setter, we have numerous illustrative anecdotes. Mr. Sherrers Bell, F.R.S., F.L.S., in his History of British Quadrupeds, thus discourses upon the qualities of one of this kind of dog:—"By far the most interesting and, if I may so employ the term, amicable animal I have ever known, was a bitch of this kind, formerly belonging to my father, which he had from a puppy, and which, although never regularly broke, was the best dog in the field he ever possessed. The very expression of poor Juno's countenance was full of sensibility and affection. She appeared to be always on the watch to evince her love and gratitude to those who were kind to her; and the instinct of attachment was, in her, so powerful, that it showed itself in her conduct to other animals, as well as to her human friends. A kitten, which had lately been taken from its mother, was sent to us, and, on Juno's approach, showed the usual horror of the cat towards dogs. But Juno seemed determined to conquer the antipathy; and, by the most winning and persevering kindness and forbearance—advancing or receding, as she found the waywardness of her new friend's temper required—she completely attached the kitten to her; and, as she had lately lost her puppies, and still had some milk left, I have often seen them lying together before the fire, the kitten sucking her kind fostermother, who was licking and caressing her as her offspring. She would also play with great gentleness with some rabbits of mine, and would entice them to familiarity by the kindness of her manner; and so fond was she of caressing the young of the dog species, that when a spaniel bitch of my father had puppies, of which all, excepting one, were destroyed. Juno would take every opportunity to steal the remaining one from its mother's nest, and carry it to her home, where she would lick and fondle it with the greatest tenderness. Poor Pussy, the mother, also a good-tempered creature, as soon as she had discovered the theft, hastened, of course, to bring back her little one, which was again to be stolen on the first favourable opportunity; until, at length, the two bitches killed the poor puppy between them, as they were endeavouring each to pull it from the other; all this with the most perfect mutual good understanding. Juno lived to a good old age, an unspoiled pet, after her master had shot to her fourteen seasons."

A curious question arising out of the game laws—Can a farmer be unlawfully on his own farm?—was argued some time ago in the High Court of Justiciary in Edinburg. It was an advocacy and suspension of a judgment of the sheriff-substitute of Dumfries, whereby Mr. Smith, tenant of the farm of Broadleydyke, Lochmaben, was sentenced to a month's imprisonment with hard labour, for being guilty of night poaching on his own farm, under 9 Geo. IV. c. 69. By this statute it is enacted, that if any person shall, by night, unlawfully take or destroy any game or rabbits in any land, whether open or enclosed, or shall, by night, unlawfully enter or be on any land, open or enclosed, with a gun, net, engine, or other instrument, for the purpose of taking or destroying game, such offender may be apprehended, &c. On the 12th of December, the complainant was served with a criminal libel, charging him with having been on his farm by night for the purpose of taking or destroying game, and guilty therefore of the above statutory offence. The case was tried before Sheriff Trotter, on the 20th of December; and his lordship having found him guilty of being upon the lands for the purpose of taking or destroying game, pronounced the sentence of which the present was a suspension. The grounds on which the conviction was sought to be quashed were—First, that the complaint was irrelevant, and ought to have been dismissed; because, while the statute drew a distinction between destroying game or rabbits, and being unlawfully on the lands by night for the purpose of the major of the libel embraced them both as one offence—
a circumstance which was fatal to the indictment in the case of Mr. Cornet (1825); further, the species facti did not amount to either of the crimes specified in the statute. In the second place, the act did not apply at all to the complainant's case, because it was his own farm, and he could never be unlawfully there under any circumstances. In the third place, it was maintained that the terms of the conviction were bad, and inapplicable to the statute, inasmuch as the qualifications, "with any gun, not, or other instrument," were omitted. The judges were unanimous in holding that, from the terms of the conviction, it must be set aside; but they were divided in opinion as to whether a farmer could be unlawfully on his own farm in the sense of the act. Lords Deas and Cowan were of opinion that he could not. Lords Handyside and Ardmillan that he could. The Lord Justice Clerk gave his casting vote in favour of the latter view, and the sentence was suspended with expenses.

Thus it would seem doubtful whether a man has a right to be on his own farm with a gun in his hand.

THE WATER SPANIEL.

This is a sturdy dog, with crisped hair, and of variable stature, according to the sporting duties he has to be engaged in. Those of this species that have to be employed on the banks of rivers, moors, or lakes, should be small, but strong and spirited. Old Gervase Markham says—"The water-dog is a creature of such general use, and so frequently in use here in England, that it is needless to make any large description of him; the rather, since not any amongst us is so simple that he cannot say where he sees him. This is a water-dog, or a dog bred for the water; yet, because in this (as in other creatures) there are other characters and forms which pretend more excellency, and figure a greater height of virtue than others do, I will here describe, as near as I can, the best proportions of a perfect water-dog. First, for the colour of the best water-dog, albeit some (which are curious in all things) will ascribe more excellency to one colour than to another, as the black to be the best and handsomest, the liver-hued swiftest in swimming, and the pied or spotted dog, quickest at scent; yet, in truth, it is not so, for all colours are alike, and so dogs of any of the former colours may be excellent good dogs, and may be excellent good curs, according to their first hardening and training; for instruction is the liquor where-with they are seasoned, and if they be well handled at first they will never smell of that discretion; and if they be ill handled they will ever stink of that folly; for nature is a true mistress, and bestows her gifts freely, and it is only nature which abuses them." He next proceeds to the clipping or shearing of this animal. "Now, for the cutting or shearing him," he continues, "from the navel downward or backward; it is two ways well to be allowed of, that is, for summer hunting, or for wager; because these water-dogs naturally are ever most laden with hair on the hinder parts, nature, as it were, labouring to defend that part most which is continually to be employed in the most extremity; and because the hinder parts are ever deeper in the water than the fore parts, therefore nature hath given them armour of hair to defend the wet and coldness; yet this defence in the summer time, by the violence of the heat of the sun, and the greatness of the dog's labour, is very noisome and troublesome, and not only maketh him sooner to faint and give over his sport, but also makes him, by his overheating, more subject to take the mange. And so, likewise, in matter of wager, it is a very heavy burthen to the dog, and maketh him to swim less nimbly and slow, besides the former offences before rectified; but for the cutting or shaving of a dog, all quite over even from the foot to the nostril, that I utterly dislike; for it not only takes from him the general benefits which nature hath lent him, but also brings such a tenderness and chilliness over all his body, that the water in the end will grow irksome under him." We have modernised the spelling of the above, in order that the quaintness of Markham may the more generally be appreciated, and his sense the more easily comprehended.

Markham's instructions, relative to training the water-dog, are excellent, and more or less applicable to all dogs.

"Now for the manner of training or bringing up of his water-dog; it is to be understood that you cannot begin too early with him; that is to say, even when you first teach him, and teach him to lap, for even then you shall begin
to teach him to couch and lie close, not daring to stir or move from that posture in which you put him without your especial license, cherishing him ever when he doth your will, and correcting him when he doth the contrary; and always observing this maxim in the first teaching of him, that you never let your dog eat or taste any meat, but when he doth something to deserve it, that custom may make it. Known food is a thing which cometh not by chance, or the bounty of your hand, but for reward or merit when he doth your commandments; and this will not only make him willing to learn, but kept to remember and retain what he learneth, and diligently to perform your pleasure without stick or amazement; the characters of your commands being so deeply imprinted in his knowledge; and to this end, you must have no more teachers, no more feeders, cherishers, or correctors, but one—for multiplicity breeds confusion—and to teach divers ways is to teach no way well; also you must be very constant to the words or directions by which you teach, choosing such as are the most significant for your purpose, and fittest for the action you would have the dog do, and by no means alter the word which you first use. When, therefore, you have made your whelp understand these several sounds or words, and that he will couch and lie down at your feet, how you please, when you please, and as long as you please, and that with a single word or a look only; you shall then proceed and teach him to lead in a line and collar, following you at your heels in decent and comely order, neither treading upon your heels, nor going before or side by you, which shows too much haste; nor hanging back, or straining your line, by the means of too much sloth, but following in decent and orderly manner, without offence either to the dog or his leader; and this kind of leading is to make the whelp familiar with you that he may love and acknowledge you, and no man else. When this general obedience is taught (which is done by observation of his going, and moving him by sights or sports, which may tempt him to stray beyond his bounds, and then to correct his offences, and to cherish and reward his obedience), you shall then teach him to fetch and carry anything you shall throw forth of your hand.”

The water spaniel is greatly improved in point of beauty by intermixture with the land spaniel. The small-sized water spaniel is, by some, considered the best to hunt with, as they make excellent retrievers, and are exceedingly active and expert at their work. Some, however, prefer middle-sized dogs, perhaps from the conception that they are a little stronger; but what they have in strength, the probability is that they lose in activity. It is from this supposition that some have even gone so far as to cross the spaniel with the Newfoundland; but, we believe, the preference, by many eminent sportmen, is generally given to the smaller-sized animal. The water spaniel is the most faithful and affectionate of all dogs. In these qualities he may be said even to surpass, certainly to rival, Arrian’s description of the hound, Hormé, which was “most gentle, and kindly affectionate.” “Never before,” says Arrian, “had any dog such regard for myself and friend, and fellow sportsman, Megillus; for, when not actually engaged in coursing, he is never away from one or the other of us; but while I am at home, he remains within by my side, accompanies me on going abroad, follows me to the gymnasium, and, while I am taking exercise, sits down by me. On my return, he runs before me, often looking back to see whether I had turned anywhere out of the road; and, as soon as he catches sight of me, showing symptoms of joy, and again trotting on before me. If I am going out on any government business, he remains with my friend, and does exactly the same towards him; he is the constant companion of whichever may be sick; and if he has not seen either of us for only a short time, he jumps up repeatedly by way of salutation, and barks, with joy, as a greeting to us. At meals, he puts us first with one foot, and then with the other, to put us in mind that he is to have his share of food. He has, also, many tones of speech, more than I ever knew in any other dog; pointing out, in his own language, whatever he wants. Having been beaten, when a puppy, with a whip, if any one, even to this day, does but mention a whip, he will come up to the speaker, covering and begging, applying his mouth to the man’s, as if to kiss him, and, jumping up, will hang on his neck, and not let him go until he has appeased his angry threats.
Now, really, I do not think that I should be ashamed to write even the name of this dog, that it may be left to posterity— that Xenophon, the Athenian, had a greyhound, called Harnée, of the greatest speed and intelligence, and altogether supremely excellent."

Flattering as this description is, we cannot think it over-drawn, for we, ourselves, have been possessed of dogs of different breeds, which have testified the utmost affection, not only to ourselves personally, but to all the members of the household, except the servants, whom some of them have marked out for a smaller proportion of their favour. We have already alluded to the motto, "Wildbrat was faithful," as belonging to the principal order in Denmark; and there is another instance of faithfulness in the spaniel, also connected with history, and which places the sagacity of this beautiful species of dog in a most favourable point of view. The circumstance is noticed by Mr. Blaine, in whose language we will here give it; but the anecdote is given by Mr. Daniel:—

"Lodebrook, of the blood-royal of Denmark, and father to Humber and Hubba, being in a boat with his ox and his dog, was, by an unexpected storm, driven on the coast of Norfolk; where, being discovered, and suspected as a spy, he was brought to Edmund, at that time king of the East Angles. Making himself known, he was treated with great hospitality by the monarch, and particularly so on account of his dexterous skill in hawking and hunting. The king's falconer grew jealous of this attention, and, lest it should lessen his merit in his royal master's opinion, and so deprive him of his place, had the treachery to waylay Lodebrook, and murder him, and conceal the body amongst some bushes. He was presently missed at court, and the king manifested great impatience to know what was become of him, when his dog, who had staid in the woods by the corpse of his master, till famine forced him thence, came and fawned on the king, and enticed him to follow him. The body was found, and, by a chain of evidence, the murderer was discovered: as a just punishment, he was placed alone in Lodebrook's boat, and committed to the mercy of the sea, which bore him to the very shore the prince had quitted. The boat was recognised; and the assassin, to avoid the torture, falsely confessed that Lodebrook had been put to death by the order of Edmund, which account so exasperated the Dane, that, to revenge his murder, they invaded England."

The water spaniel is of considerable antiquity. He is sculptured on many Roman remains; and Colonel Smith thinks him identical with the Canis Taurus lauded by Xenophon.

THE RETRIEVER.

This is a useful dog, but of uncertain parentage. He has been called an indefinite dog. He is required to act many parts—to make a tolerable pointer, a better setter, and a handy hunter, in thick covers after wounded game. To be perfect in his calling, he should, on the very glance of your eye, spring among tangled woods and briars, or rush into the water, pick up, and bring out a dead or wounded bird. He is necessarily an animal of great canine attainments, full of intelligence of the highest order; remarkably quick in his apprehension, adventurous, and swift of foot. This kind of dog is a necessary appendage to a regular shooting establishment. It is astonishing how sagacious he becomes by proper training, and how much his labours facilitate the acquisition of a good day's sport. The great error to guard against, is the haste and impatience which are embodied in his nature.

Speaking of the desire which every thorough sportsman has to have every species of dog adapted to the peculiar kind of game to be hunted, Mr. Blaine says that he knew such a one, who, when ranging his pointers in advance, was always followed by a retriever of very rare qualities. His pointers, also, did their duty to admiration; and when they came to a steady point, bang from each barrel followed, and two birds usually fell; the pointers remained on the spot, motionless witnesses. A move of the sportsman's hand, and the "away" to the retriever, sent him off like lightning, and he returned with both birds. The ability of this dog was such, that when two birds fell, he would hold one by the neck, and the other by the wing, near to the body; by which device neither bird would be injured, nor himself encumbered. In pheasant-shooting, likewise, the excellent discipline of this dog, and his extra-
ordinary tact, were the delight of all who saw his performances. Training is everything. It operates on the canine as it does on the human species. It gives them knowledge, understanding, and intelligence. In these expressions we hope to be considered as not exciting the dog to an equality with the man. We employ them because we know of none better to convey our meaning. To a certain extent, the dog is possessed of all the qualities they express. Who will gainsay that he has not knowledge, understanding, and intelligence?

"To see," says Mr. Apperley, speaking of the feeding of a kennel of hounds—"to see sixty couple of hounds, all as hungry as tigers, standing aloof in the yard (as is the practice in some kennels), and without even hearing, much less feeling the whip, not daring to move until the order is given them to do so! And what is the order given? Why, at the words, 'Come over, bitches,' or, 'Come over, dogs,' every hound of each individual sex comes forward, as the sex it belongs to may be called for, leaving those of the other sex in their places. Then the act of drawing them to the feeding-troughs is an exceedingly interesting sight. Often, with the door wide open, and the savoury meat in their view, the huntsman has no use for his whip, having nothing to do but to call each hound by his name, which, of course, he readily answers to. The expression of countenance, too, at this time, is well worthy of notice; and that of earnest solicitation, of entreaty, we might almost say of importunity, cannot be more forcibly displayed than in the face of a hungry hound awaiting his turn to be drawn. He appears absolutely to watch the lips of the huntsman, anticipating his own name." Here the qualities to which we have alluded are exemplified in a marked degree.

The retriever is sometimes a cross between a Newfoundland and a pointer; and, indeed, Newfoundland dogs, themselves, act as retrievers. The general tractability and docility of these dogs render them easily to be taught to do almost anything but speak. Some have shot woodcocks to them. In reference to retrievers being trained by children, opinions differ. "Six years since a gentleman bought a retriever, that had been trained by children to fetch or bring stones from the bottom of a river, until his teeth had been broken with the practice, and he proved altogether worthless as a sporting dog. It is now upwards of six times six years since I committed the very same blunder, and my dog seems to have been even worse than his, for I never could get him to take the slightest notice either of gun or game; and so lively a recollection have I entertained of the circumstance ever since, that I never dreamed afterwards of buying a dog until I had tried him at the actual work for which I wanted him. His dog was trained by children; so was mine; and with my dog, at least, the children had done their part to admiration. The dog knew his lesson perfectly: the spike-collar could not have done it better, if it had been applied at twelve months old, to make him dive for stones, and fetch them up from the bottom of a river. The mistake, in both cases, was in keeping the dogs at child's play too long and too exclusively to admit of their being turned into sporting dogs afterwards; or, rather, I should not have bought a dog for a retriever that had done nothing but fetch stones for children until his teeth were broken.

"I have now in my house a little animal, a cross between a Blenheim spaniel and a foreign nondescript. He belongs to my children, and they have taught him tricks enough to qualify him for an exhibition; his teeth are all gone with gnawing sticks and fetching stones, and he is as fond of these things now as he was six years ago as a puppy; but, notwithstanding all this, a better little dog never hunted a rabbit out of a furze-brake, or a water-hen out of a bed of rushes; and, whether he is standing in a corner, or performing any other of his numerous antics, the click of my gun-lock will send him screeaming to the house-door."

Training is everything, we repeat; although a spaniel or retriever should range close on flat ground, he ought always to enter and remain in cover, however far from it a shooter may think proper to station himself. Nothing can be more annoying than an animal scampering on dry leaves in and out of a wood, effectually preventing our hearing a cock rise, and all kinds of game from approaching us. Neither should he be allowed to quit a wood to hunt the banks of a brook for water-hens. A pointer that has
been used as a snipe dog the preceding winter, will bring a man down from the top of a grouse-hill, in August, to the well-known bog, for a worthless snipe; and a spaniel will make for anything in the shape of water, to potter on the stale scent of water-hens, and soon acquire the vile habit of hunting straightforward, without tack or traverse.

"While making my annual collection of brown feathers, during the late frost," says a follower of the angle, "I was reminded, more than once, of the device which has often enabled me, when fonder of wild-fowl than at present, to recover a mallard lying on the edge of dangerous ice, without risking the loss of a valuable retriever. Ten-to-one other men have had recourse to the same ficelle; but, as it may be new to some, I will mention it.

Having nearly lost a valuable retriever, and risking my own life to save his, I bethought myself of an old salmon-rod, to which I attached a sufficiency of whipcord, with four large hooks tied, back to back, at the end of it. The rod was an old stiff travelling jack-of-all-trades, in five pieces, portable, and fit for service at once. My attendant carried this, of course, and, when required, mounted it while I was loading. Very little practice enabled me to hook a duck within five-and-twenty yards. When feathers were scarce, and I was particularly anxious to secure a drake, if beyond the reach of my line, I attached a cord to the retriever's collar before sending him into dangerous ice.

"When ascending a river I kept about half a gun-shot from the bank, my man following rather more than a gun-shot in the rear, and close to the river. When ducks had been marked down, I approached at right angles to the direction of the stream, making allowances for the birds swimming up, which they generally do after alighting.

"I think I have observed, that when a duck rises wild, and, after making several circles in the air, settles near the place from which he rose, there is reason to expect others near him—very often a single bird of the other sex. In this case, both birds will occasionally be very close, if no noise be made when the single bird rose. At all events, a duck that drops in a hedge, or other thick cover, at some distance from a pond or river, will gene-

rally let you get near enough to be picked up, or recovered by the retriever."

The value of a retriever is sometimes very considerable. "At the Kingston assizes, an action (Clegg v. Hobbler) was tried to recover the value of a dog shot by defendant. The dog was a retriever puppy, three months old, and very well bred. He stayed away from home, and nothing was heard of him for several days, when he was brought home dead. The dog had gone into a field belonging to the defendant, where there were some sheep; and, while he was chasing them about, defendant came with a gun, and at once shot him dead.—Baron Alderson inquired of the plaintiff what kind of retriever the dog was.—The plaintiff replied, that he really was unable to tell how he was bred. All he knew was, that he was a retriever, and that his father was a very valuable animal.—Baron Alderson said, that all sorts of dogs might be trained as retrievers; and he had even heard of a pig being a retriever.

—Mr. James: Yes, my lord, for truffles!—

The learned judge said he should like to hear something more respecting the breed of the dog.—Mr. James: My lord, the father of the dog is here, and he shall be produced presently.—Witnesses were examined to prove that the dog was shot by the defendant, and the deceased's father was then placed on the counsel's table. He was a fine handsome animal, and it was stated that his sporting qualities were first-rate. He appeared very much dissatisfied with his novel position among so many wigs.—Mr. Brooks, on behalf of the defendant, said, that at the time in question, the sheep that were in the field were fat, and ready for the butcher. They had been worried by a dog two or three nights before; and, on this night, he supposed it was the same dog; and, on his going into the field, he found him chasing the sheep about, and shot him.—Baron Alderson said, that he had acted illegally. Even if the dog had worried the sheep, a person was not justified in destroying him until he had tried to get him away by fair means. Ultimately, on the learned judge's suggestion, it was decided that defendant should pay all plaintiff's costs out of pocket, and a certain sum as the nominal value of the dog."
Thus, it is illegal to shoot a dog upon your own property, even although he is in the act of chasing and frightening your sheep, until you have tried to make him desist, or to drive him from the field by fair means.

GENERAL REMARKS ON SHOOTING DOGS.

After the sportsman has secured his sporting quarters, the next consideration is his dogs. What kind shall he take? If he has them, good and well; if not, the sooner he procures them, and gets to know them, the better. Dogs are not put into condition for work in a week, nor yet in a month; and a man really fond of sport, will, himself, take the greatest interest in the exercising of his dogs, so as to prepare them both in wind and in foot for this, the hardest of all work for them; and if men would themselves take their dogs out for their daily walks along the road, they would feel the benefit of it in August, by their own feet being in better order for walking, and by their dogs knowing them well, and beating for their master, instead of for the keeper. Colonel Hawker tells us to use “well-tried and staunch dogs;” and others say, that “dogs for grouse-shooting ought to be first-rate in every respect—the highest bred, and best disciplined;” though the colonel prefers setters, and advises, when practicable, a mixture of pointers and setters. In Daniel’s Rural Sports, in Lascelles’ Familiar Letters on Sporting—in fact, in every book on the subject, but in none more succinctly and better treated than in Blaine, we find the same thing—“To have good sport, you must have good dogs.” What can be more disappointing, or annoying, than to find, on arriving at the moor, that when you want to be killing game, you have to be dog-breaking?—that the dogs either won’t range at all, or else run up more birds than they point—and that when you do get a shot, you have to shout until you are hoarse to make them “down charge,” putting up two or three birds under your feet; and, having loaded, put yourself into a fever of perspiration with thrashing them for “running in,” and snapping the bird you have killed, spoiling your grouse, your temper, and your shooting for the rest of the day. This may seem an unusual case; but any one who shoots chiefly on subscription moors, will bear us out, that more than half the men one meets with, are provided with a team of dogs not one iota better than we have described. Where, then, is a man to procure good dogs? is the natural question. Let him go to a really respectable breaker, or keeper; have a good trial, and give a good price. Some parts of the year are certainly not favourable to see dogs well tried, especially when birds are sitting, and have very little scent; and if it is necessary to see whether a dog is “free from bare,” it is difficult to find one without going into corn or moving grass. The dog’s general style, working to hand and obedience, however, can be judged of, as also his condition, and the hardness of his feet; and if he has been shot over for one or more seasons, so much the better. But, to any one who wishes to shoot in comfort, we would say, avoid what is called “a promising young dog, just out of the breaker’s hands, and ready for work,” unless you can have a really good trial, and see powder burnt over him. No one ought to take less than two brace of dogs to the moors, so as to be able to change them at noon, and keeping the best for the afternoon shooting. It is true good setters will go all day, and some every day in the week; and though we believe some pointers are capable of almost the same exertion, we have never met with them; still, it is hard upon the animal, however courageous, to tax his strength beyond certain limits, and is, besides, a comfort to oneself to let out a fresh brace after luncheon. By the way, some men have their spare dogs led along with them, which is a great mistake, as, with the excitement of watching their master shoot, and the pulling against the man who leads them, they are never resting. We knew one who liked his dogs to begin the season, though not over fat, with plenty of flesh on their ribs. He thought they worked better for it, and very soon got to their hard-condition trim, and doing their work better than dogs that are kept thin by poor diet; for if dogs are properly fed before going to the moors, no one can have them in spare working condition with common road exercise, unless he give them fifteen or twenty miles a day after a horse, like greyhounds. He fed his dogs pretty much the same all the year round, with the exception of substituting “greaves” for flesh in hot
weather; good boiled oatmeal, flesh (or greaves), with potatoes boiled in the soup, and occasionally cabbage sliced into it, and plenty of salt, which he thought the best food for dogs at all times. When at the moors, and one has not the same convenience for cooking, he used barley-flour instead of oatmeal (as it only requires scalding), with “greaves” and salt, and milk, if he could get it.

The miserable accommodation for dogs that one generally meets with on subscription moors is well known, and mostly consists of some wretched barn or outhouse, with the roof half off, no door, and the floor as wet as a snipe-ground. In this case, the comfort of having your own servant will, in itself, repay the expense of taking him down with you, instead of trusting to some man whom you may hire as bag-carrier, &c., at four or five shillings a day, and who, having no interest in your dogs, neither feeds nor takes care of them as he ought. Your own man will, with a few boards, &c., make the best of the place in which they have to live. He will also prepare their food properly before you go out in the morning, so that they may be fed immediately on your return, instead of being left for an hour or so, during which they have curled themselves up to sleep, and are too stiff and tired to leave their benches to eat. He will also let them out for a few minutes the first thing in the morning, whilst he is cleaning out their kennel; putting in a little fresh straw, if required, and filling their troughs with fresh water, &c. All dogs’ feet should be dipped in strong salt and water immediately on coming off the moors; and a couple of minutes with the “dandy-brush” will, if they come in wet, cause them to dry in half the time that they otherwise would. Dogs, in hunting, are sometimes bitten by vipers. These reptiles, the only venomous of the three British varieties of the snake, abound on some moors; and, unless the bite is promptly treated, a valuable dog’s life may be lost. Sweet oil, the fat of vipers, turpentine, and numerous other remedies, are advised; but the common “burdock” is an excellent specific. This was told us by an old poacher; and, though we constantly used to lose dogs, sheep, and even cows, notwithstanding all our care, before we knew of this remedy, we never lost another animal afterwards. The mode of using it is to slice or scrape a large handful of the root, and pour upon it about two quarts of boiling water; when this infusion is cool, foment the bitten part with it many times a day, and pour about half a wine-glass of it down the dog’s throat three or four times a day. We never knew this to fail, and the dog is fit for work in a couple of days. This subject, however, will be treated more at large when we come to speak of the diseases and accidents to which dogs are subject.

**BREEDING, BREAKING, AND TRAINING SPANIELS, SETTERS, AND POINTERS.**

There has been much written on this subject; and dog-breaking, at the present day, is pretty much the same as it was in the time of Gervase Markham. The art of breeding, however, has occupied the attention of many able sportsmen. In a state of nature, the sexual appetite of a bitch occurs only once a year; but, in a state of domestication, it occurs oftener, within six, eight, or nine months. This arises from the difference of food upon which the animal is fed, and the consequently changed condition of its habits and constitution. In breeding dogs, the in-and-in system has had both its advocates and its opponents. One interested in this subject says, that there have been various animals of the finest qualities bred from parents very nearly related to each other; and this is perfectly true: if we have a male and female full brother and sister, and both of very fine quality, the chances are that we shall have a fine progeny. “I had a very fine greyhound from this method; at the same time, one of the whelps was quite an idiot, and I was forced to destroy it when about two months old. My personal experience, with regard to the lower animals, is not very extensive; but, being naturally fond of the study of natural history, I have taken every opportunity of gaining information; and I find among farmers a constant habit of introducing a male from some other family. Gamekeepers pursue the same plan with regard to dogs; they call it introducing fresh blood: they generally adhere to the same kind, but not always: the best greyhounds have a cross with the bulldog; and, I believe, though I speak with diffidence,
that the best race-horses are all cross-bred—that is to say, they are the cross produce of various kinds, such as the Barb, the Arab, the English and Spanish horses,* the latter an undoubtedly cross-breed in itself, from horses introduced into Spain by the Moors; and, however good many of the pure or thorough-bred horses—such as Barbs and Arabs—may be, yet they are no match, as regards speed, with the cross-breeds of our own country. They may have more endurance in the country where they are bred, because, being bred there, they are more suited to the climate and nature of the ground; and this is the case with every thorough-bred animal whatsoever; if you alter the circumstances, you alter the animal to suit them. The Skye terrier in England, after two or three generations, is not the Skye terrier of the Isle of Skye; its habits and form alter greatly. I used often to speculate and wonder why it should have such short and powerful legs and long body; but one day, while watching some puppies of pure breed at play, I saw the mystery explained. There was a mound of earth, standing at an angle of about 70°, the surface of which being loosened by frost, rolled down at the slightest touch; the puppies, with their short strong legs and elongated bodies, climbed up this with little difficulty, and, having got to the top, turned round, and, thrusting their fore feet forward, slipped down on their bellies, kicking themselves along with their hind feet. This operation, which they repeated over and over again, seemed to afford them infinite gratification, and the surface of the hillock became grooved by their breasts being ploughed repeatedly down it. Here was a wonderful instance of the form of the animal being adapted to the locality. The Isle of Skye has a singularly rocky and uneven surface, and these short-legged and long-backed animals are admirably suited to it. These dogs have a very thick skin, clothed with a large quantity of long hair, both calculated to protect them against falls.

"It should be observed, that the system of breeding-in, in both wild and domestic animals, is not by any means a haphazard affair, as it certainly is with the human race. With domestic animals we always select the finest;

* This we have already shown in our division on the horse.
partake, in a great degree, of the properties of the mother.' 'I have tried,' says the sporting
baronet, 'many experiments by breeding
in-and-in upon dogs, fowls, and pigeons; the
dogs became, from strong spaniels, weak and
diminutive lap-dogs; the fowls became long in
the legs, small in the body, and bad breeders.'
Sir William Clayton, in his Treatise on Grey-
hounds, is also, in some degree, unfavourable
to breeding akin. He says—'If continued
for some litters, a manifest inferiority of size,
and a deficiency of bone will soon be visible,
as well as a want of courage and bottom,
though the beauty of the form, with the except-
tion of the size, may not be diminished.'
Mr. Beckford is also averse to consanguineous
breeding among dogs. 'A very famous sports-
man,' he says, 'has told me, that he fre-
quently breeds from brothers and sisters. As I
should be very unwilling to urge anything in
opposition to such authority, you had better
try it; if it succeeds in hounds, it is more, I
believe, than it usually does in other animals.'
It is remarkable that the ancients, although
they advocated the system of in-and-in breeding
among all other domestic animals, yet
were averse to it in the dog. In the Geo-
pontier, l, xix. c. i, we are cautioned against
breeding between individuals of the same
litter. Conrad Gesner, on this subject, ob-
serves, 'that the very best dogs are bred each
in their own line, or from parents of a similar
kind; but an extreme care in huntsmen for
improvement, has led them so to mingle dif-
fferent breeds as to make the varieties almost
innumerable.'

"Like begets like," is a truism; and in no
instance is it more just, nor in any more im-
portant than in dog-breeding; consequently,
it is not easy to be too careful that the quali-
ties and form of both parents be as perfect as
possible. As no bitch is without some defect,
so it should be remembered, in selecting a
mate for her, that the dog should not only be
entirely without that particular defect, but
even superabundantly furnished contrariwise.
If the strain borders on the light and leggy,
do not perpetuate the defect, but choose a dog
not coarse, but strong and well trifled. If
the bitch incline to be floc (tender), fix on a
dog for her that is singularly hardy. The
qualities also must be attended to in breeding,
for they run as much in the blood as the form
does. If the bitch, though exquisite in figure,
be yet wanting in metal, give her a mate with as
much dash and determination of the right kind
as possible. If, on the contrary, though well-
shed, she is given to skirting, to run riot, to
hobble, or to any other hurtful propensities,
cross it with super-excellence, in the opposite
quality in the dog selected for her. Skirting
particularly by removing the breed, by letting
the skirter be mated with a thorough line hunt-
ing hound. It is by judicious crossing that the
puck is rendered complete. Let masters of
hounds be very careful, likewise, in entrusting
their favourite bitches to the care of the atten-
dants of other kennels. There is infinite risk
and chance of deception in this, because,
where the stallion, be it fox-hound, grey-
hound, or pointer, is of great celebrity, the
probability is, that such dog is already fully
engaged, in which case another dog may be
fraudulently substituted, and the bitch served
by one that, instead of mending the breed,
may increase its defects. On this subject
Colonel Cook well observes—'It is the custom
to send bitches to the fashionable stallions of
the day; for instance, to the late Mr. Meynell's 'Gusman,' Lord Fitzwilliam's
'Hardwick;' Lord Yarborough's 'Ranter,'
Mr. Ward's 'Charon,' the Duke of Rutland's
'Topper,' the Duke of Beaufort's 'Justice,'
the Duke of Grafton's 'Regent;' Lord Lon-
dale's 'Ruler;' Mr. Smith's 'Champion,'
Mr. Munster's 'Collier,' Lord Myddleton's
'Vaniiter;' &c.; but, as it generally happens
that your brood bitches go to heat much about
the same time, it is therefore not very probable
that one stallion bound can ward many bitches,
besides those of the owner; nor is it reason-
able to expect, in the height of the season,
that the dog-bounds can be left at home to
ward bitches from other kennels. I would
suggest, in order to be more certain of your
breed, that you send your bitch to a well-bred
dog, brother, if possible, to the stallion bound;
and, to prevent any mistake, order your ser-
vants to see the bitch warded.'

We have remarked, in reference to the
horse, that, as a general rule, 'like produces
like;' and we think the same will be found to
hold good in reference to the dog. Mr. Beck-
ford advises us to consider the size, shape,
THE DOG, AND ITS VARIETIES;  

colour, constitution, and natural disposition of the dog intended to be bred from, as well as the fineness of his nose, his stoutness, and mode of hunting. "On no account," he says, "breed from one that is not stout, that is not tender-nosed, or that is a skirter." Similar instructions to these are set forth by Somerville, in the following lines:

"Observe with care his shape, sort, colour, size;  
Nor will sagacious hunters less regard  
His inward habits; the vain babbler shun,  
Ever loquacious, ever in the wrong;  
His foolish offspring shall offend thy ears  
With false alarms, and loud impertinence.  
Nor less the shifting ear avoid, that breaks  
Illusive from the pack; to the next hedge  
Devious he strays; there every means he tries;  
If haply then he cross the steaming scent,  
Away he flies vain-glorious, and exults  
As if the pack supreme, and in his speed  
And strength unrival'd. Lo! east far behind,  
His vex'd associates pant, and lab'ring strain  
To climb the steep ascent. Soon as they reach  
Th' insulting boaster, his false courage fails;  
Behind he lags, doom'd to the fatal noose,  
His master's hate, and scorn of all the field;  
What can from such be hop'd but a base brood  
Of coward curs, a frantic, vagrant race."

In breaking dogs to make retrievers, systems differ in different countries. Following one who has had much experience of various systems, we find that the one practised by the French differs from that practised in England, equally in its process and results—it is that of force, the spiked collar being universally used; and, although this expedient is certainly a severe one, yet it is affirmed that it produces a result which the suaviter in modo fails to effect, except to a certain extent, in the case of the Newfoundland and water spaniel. As the fortiter in re, or compulsory system of the spiked collar, is harsh, and the punishment inflicted severe, it must be remarked, that the experienced breakers of France find it inexpensive to commence with any young dog till he is ten or twelve months old, the severity of the training having the effect of cowing and intimidating dogs of a younger age. The breakers would, also, seem to be averse to any previous instruction being imparted to puppies, either by children or other means, as that always renders their operations with the spiked collar more difficult. It was on one occasion mentioned to a dog-breaker of note, that a dog was about to be sent to him to be taught, and that it had already received some instructions by gentle means, and that he would fetch and carry tolerably. His reply was—"Tant pis. J'aurai plus de peine avec ce chien la; il sera plus entêté, et plus difficile à dresser." This circumstance is alluded to, because an opinion is by no means uncommon, that dogs should be taught to fetch and carry as soon as they are able to run about; and some have even recommended children as their best instructors; and, judging from the successful results in one or two cases, have expressed themselves strongly in favour of this method, intimating it to be the right one, and that universally practised in France. With every deference to such sportsmen, it may safely be thought that they are making a rule of the exception, and, at the same time, confounding two things which are totally dissimilar, as the compulsory system differs "tutto cielo" from the mild and gentle one, both in its process and in its results. It is readily admitted that you cannot begin too early to teach dogs to be docile and obedient, and to impart preliminary instruction to them, when it is intended to teach them to fetch their game by gentle means; but it cannot be conceded that children are the best instructors, because experience has frequently shown that they are the very worst if a dog is expected to carry anything beyond a ball, a stick, or a stone, and to be used for sporting purposes—simply because dogs, taught by children, are generally in the habit of playing with whatever they fetch and carry, and rarely or ever pick it up at once, or immediately return with it when they have picked it up. On the contrary, they mostly drop it several times, and, after finally securing it, commence a series of gambols before they return, infinitely to the delight and satisfaction of themselves and the children with whom they are playing. The consequence of this is, when a dog so taught is taken into the field, he is almost certain to mouth his game, drop it, and pick it up again several times, leaving the ground covered with feathers; and, perhaps, when he finally seizes the bird, he will stand wagging his tail, looking his master in the face with infinite satisfaction to himself, as he has been in the habit of doing with his instructors, which, doubtless, pleases the children, and excites their benevolent attachment; but it is,
nevertheless, very vexations and annoying to the sportsman. Many dogs of this description have been taken to the field; and, in a preceding page, we have adduced an instance in the field; but they never can be depended on, except, perhaps, Newfoundlanders, or water spaniels, as these two races of dogs are easily broken to bring their game either on land or from the water, their instinct inducing them strongly in that direction, although it may be doubted whether they are ever so perfectly taught by gentle, as by compulsory means. Dogs taught to fetch their game by gentle means have been pronounced uncertain in their obedience; on some days taking the water unhesitatingly, and bringing perfectly; and, on others, no earthly power being able to induce them either to take water or to fetch their game. This generally occurs whenever anything has arisen to ruffle their tempers. Indeed, we have heard of a Newfoundland, a first-rate retriever, who had been taught by gentle means, and who, when sulky from being scolded or thrashed, would not stir one inch; whereas we have never known a dog refuse to go and fetch his game either on land or from the water, whatever his breed might be, who had been thoroughly taught with the spiked collar by a competent instructor.

Although this “uncertainty” and “sulkiness” may have, in some instances, exhibited themselves, we are far from believing such exhibition to be either general or conclusive that severe measures are the best for breaking or training a dog. We have seen the effects of gentleness upon the horse; and we have no doubt that gentleness used towards the dog is by far the most potent and effective educator. In proof of this, the following account of a canine performance, which took place in London some years ago, will be found exceedingly interesting. It was published in the *Lancet*.

“Two fine dogs, of the Spanish breed, were introduced by M. Léonard, with the customary French *politesse*—the largest, by the name of M. Philax; the other, as M. Brac (or Spot). The former had been in training three, the latter, two years. They were in vigorous health; and, having bowed very gracefully, seated themselves on the hearth-rug, side by side. M. Léonard then gave a lively descrip-
meat, and give it to Brae; and then Brae was told to give it back to Philax, who was to return it to its place. Philax was next told he might bring a piece of bread, and eat it; but, before he had time to swallow it, his master forbade him, and directed him to show that he had not disobeyed, and the dog instantly protruded the crust between his lips.

"While many of these feats were being performed, M. Léonard snapped a whip violently, to prove that the animals were so completely under discipline that they would not heed any interruption.

"After many other performances, M. Léonard invited a gentleman to play a game of dominos with one of them. The younger and slighter dog then seated himself on a chair at the table, and the writer and M. Léonard seated themselves opposite. Six dominos were placed on their edges, in the usual manner, before the dog, and a like number before the writer. The dog having a double number, took one up in his mouth, and put it in the middle of the table; the writer played a corresponding piece on one side; the dog immediately placed another correctly, and so on, until all the pieces were engaged. Other six dominos were then given to each, and the writer intentionally played a wrong number. The dog looked surprised, stared very earnestly at the writer, growled, and finally barked angrily. Finding that no notice was taken of his remonstrances, he pushed away the wrong domino with his nose, and took up a suitable one from his own pieces, and played it in its stead. The writer then played correctly; the dog followed, and won the game. Not the slightest intimation could have been given by M. Léonard to the dog; this mode of play must have been entirely the result of his own observation and judgment. It should be added that the performances were strictly private. The owner of the dogs was a gentleman of independent fortune, and the instruction of his dogs had been taken up merely as a curious and amusing investigation."

Mr. Richardson adduces the following:—

"Some years ago, a Spaniard, named Germundi, exhibited a company of performing dogs in the different towns of Great Britain and Ireland. In Dublin, where he made some stay, he occupied, with his company, the large building at the corner of D'Olier Street, which is now the handsome shop of Messrs. Kinahan. The performances of these dogs were extremely curious. They danced, waltzed, and pirouetted. One, in the costume and character of a lady, sat down to a spinning-wheel, which he kept in motion for a considerable time.

"The company was divided into two groups; one half appearing in dresses of a red colour, and the other being attired in blue. The blues occupied the model of a fortress, which the red troop attacked, drawing up their artillery in front, and opening a heavy fire upon the enemy, which the blues returned with their cannon from the fortress. The reds were, however, at length, victorious; the fortress tottered, and the reds dashed across the defences. Suddenly the works blew up with a tremendous crash, and several dogs, on both sides, lay motionless as they fell, apparently severely maimed, if not entirely dead. When the effects of the explosion had died away, the proprietor advanced, and pulled the performers about as dead dogs, to the no small horror and amazement of the spectators; but immediately, on the dropping of the curtain, the apparently wounded, or dead dogs sprang to their feet, and resumed their proper places.

"The next scene introduced one of the dogs as a captive between two of his comrades, all attired in military costume. The captive, being condemned as a deserter, was sentenced to be shot, and the sentence was carried forthwith into execution by his canine comrades. On being fired at he fell, struggled convulsively for a few seconds, then apparently died; in this state he was dragged about the stage; his comrades then placed him in a barrow, and wheeled him away. He subsequently appeared placed in a bier drawn by dogs, with likewise a canine driver, who flourished a whip over his companions, and, with a procession of the whole company, attired as soldiers, moved slowly to the solemn dead march, deposited their comrade in the grave, and thus concluded their performance. These dogs were of various descriptions—pugs, poodles, mongrels.

"There was an interlude of young puppies, who tumbled head-over-heels in various diverting attitudes; after which he introduced a fine specimen of bulldog, which the exhibitor called his fire king. This dog was trained to
exhibit in the midst of a brilliant display of fireworks, and nothing could exceed the courage he preserved when wholly surrounded by flames, or the resolution he manifested not to quit his position until the fire was entirely extinguished. All this was the result of gentleness.

"Many a good
And useful quality, and virtue too;
Fidelity that neither bribe nor threat
Can move nor warp; and gratitude for small
And trivial favours, lasting as the life,
And glistening even in the dying eye."
